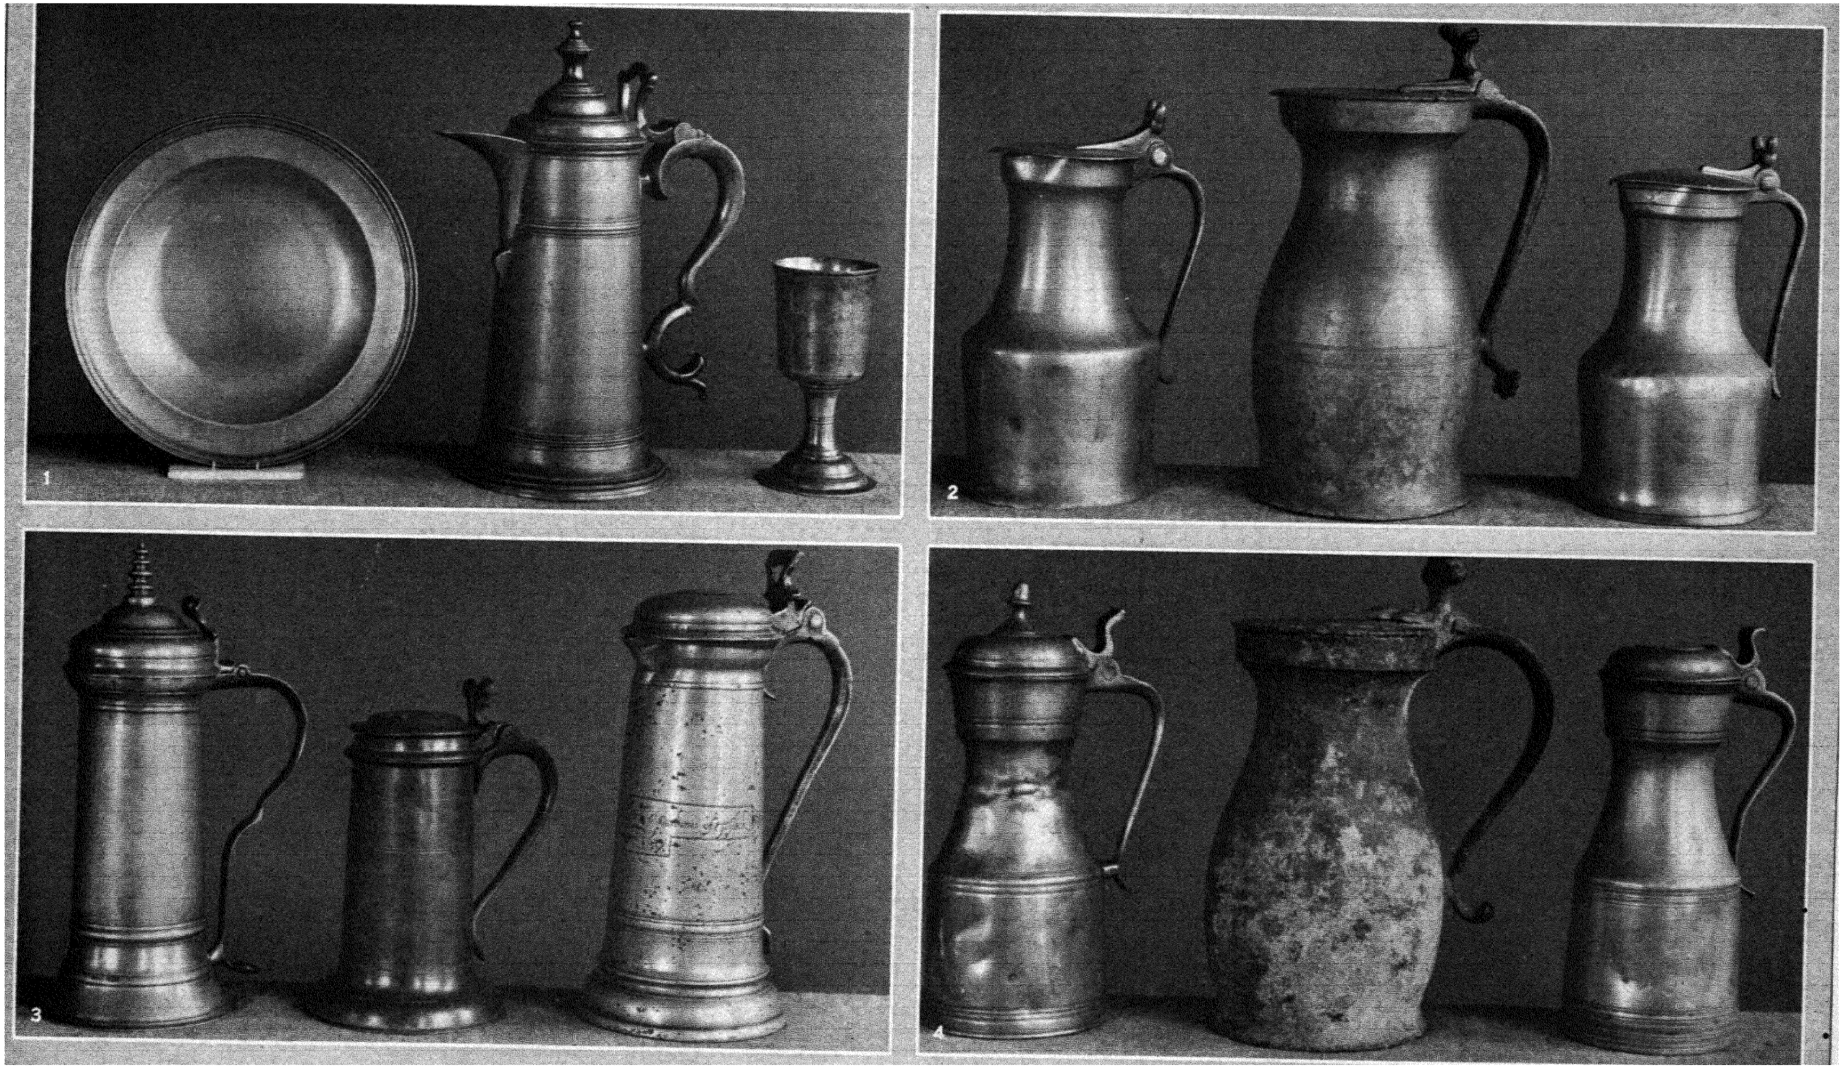
The use of pewter followed three main lines: it was employed for church vessels, for domestic purposes, and in a less degree for what might be termed civic functions. In England pewter was already used in the service of the church in early mediaeval times. Chalices of pewter had replaced wooden vessels before the end of the 11th century; but, in 1175 the Council of Westminster proscribed this metal and bishops were forbidden "to bless a chalice of pewter." From that time until the 15th century it was customary to bury a pewter chalice with the priest. Various references are found from which it may be inferred that in addition to their silver vessels many churches possessed a chalice of pewter or tin destined to be buried with the priest. Such chalices have frequently been found on the opening of coffins. Cruets for the wine and water of the Mass were also of pewter. After the Reformation and throughout the 17th and 18th centuries a large number of pewter vessels are found, especially flagons. The canon of 1603 ordered that the wine should be "brought to the Communion table in a clean and sweet standing pot or stoup of pewter if not of purer metal." Many such flagons still survive, dating from any time up till the end of the 18th century; they follow the shape of the contemporary silver vessels, the commonest being of cylindrical form with bold scroll handle and flat or domed lid. Alms dishes, patens and collecting plates are also found; a set of four beautiful dishes with enamelled centres dating from the 17th century, belong to the church of St. Katherine Cree in the City of London. Complete sets of communion vessels in pewter are rare. The Elizabethan communion cup with its band of engraved ornament is occasionally to be met with in pewter, a rather puzzling fact when it is remembered how common silver was at that period. It seems clear that generally speaking chalices in pewter were merely a makeshift. The churches of Scotland are much richer in communion plate than those of England. At the time of the Reformation St. Giles's Church, Edinburgh, possessed a pair of pewter candlesticks for the high altar which were evidently considered of value. Till the end of the 18th century pewter was much in use, and more and finer vessels are found there than in England: they comprise communion vessels including the beaker form of cup in common use in the north-eastern parts of the country, basins for collecting alms, and a large number of communion "tokens." On the Continent pewter had a much wider application in church vessels and furniture; while chalices and patens were ordered to be of silver at least in part, the cruets were frequently of pewter. This metal was also used for holy-

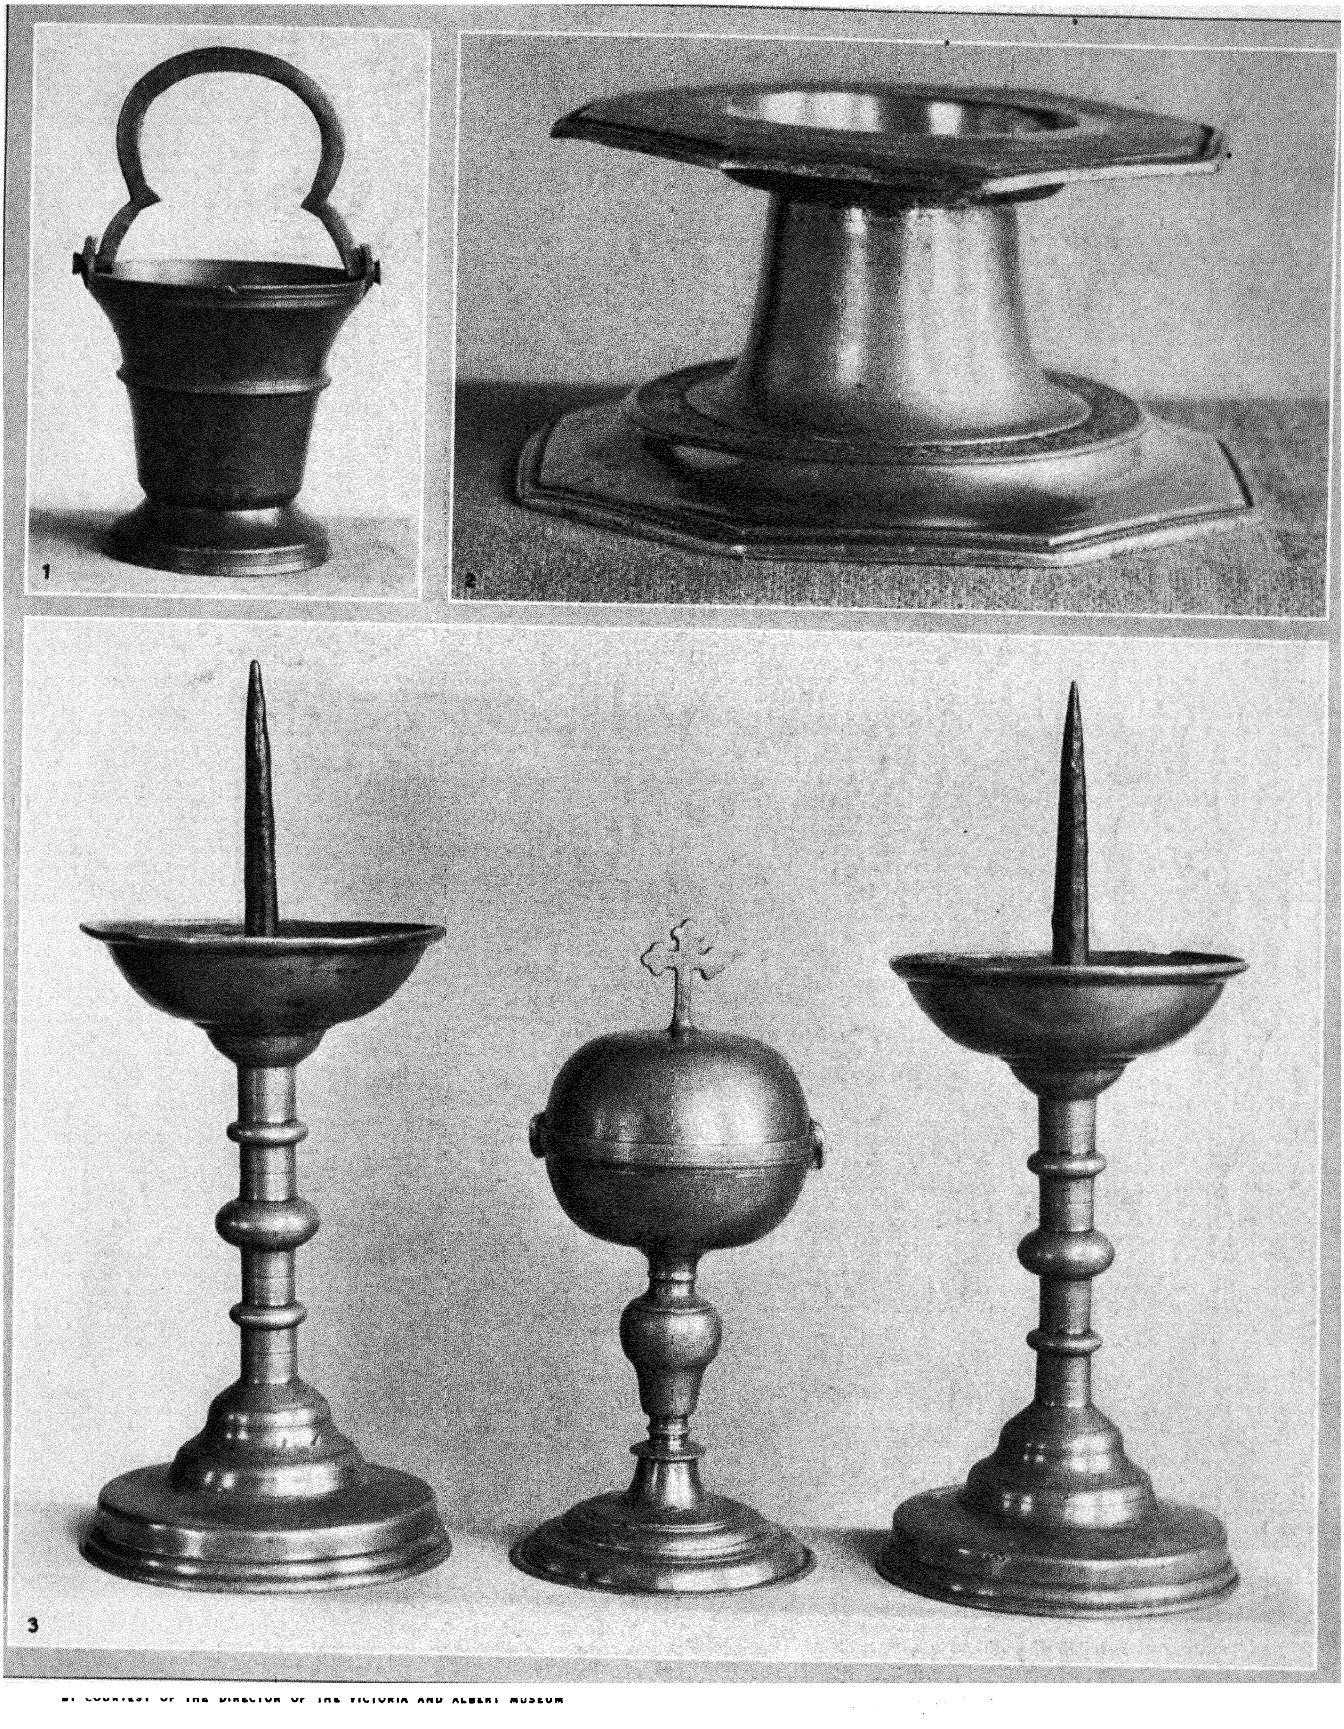


ENGLISH AND SCOTCH ECCLESIASTICAL AND DOMESTIC VESSELS

1. Set of English communion plate from Midhurst Church, Sussex: (a) Communion plate; pewter marks, crowned rose bearing the words "Made in London" and x crowned, 18th century. Diam. 10". (b) Communion flagon, dated 1677. Ht. 13". (c) Communion cup, c. 1670. Ht. 6.4"
2. English measures: (a) Late 17th century. Ht. 10.8". (b) Late 17th century. Ht. 10.5". (c) Early 18th century. Ht. 13.3". Marker's mark of John Home, Snow Hill, London
3. (a) Communion flagon. Pewter. English, 17th century. Ht. 12.8". (b) Communion flagon. Pewter, inscribed "Decemb. 25 1698 Horton." English. Ht. 9.4". (c) Communion flagon. Pewter, inscribed "Willyam Hunt Arter Dauson, churchwardanes of Fosdick. Mark I.E. with a unicorn. The original form has been altered by hammering a spout in the lip. English. Ht. 13.3"
4. English and Scotch measures and flagons: (a) "Tappit-topped hen" flagon, holding a Scotch pint. Scotch, late 17th or early 18th century. Ht. 12", diam. (base) 5". (b) English pewter encrusted with sea-water deposit. Late 17th century. Thumb piece in form of Prince of Wales's feathers; finishing in a *fleur-de-lys*. Ht. 13", diam. (body) 6.5". (c) "Tappit-topped hen" flagon, holding a Scotch pint. Scotch, late 17th or early 18th century. Ht. 11⅜", diam. (body) 4⅞"

FRENCH AND SWISS PEWTER, 16TH CENTURY

1. "Temperantia" ewer, by François Briot of Lorraine, *c.* 1580–90. Signed F.B. It is decorated with figures of the cardinal virtues. (*See* Plate V., fig. 1, for salver.)
2. Large flagon; a guild tankard of silvered pewter cast in relief, with emblematic figures of virtues, vices, muses, and planets, and on the handle figures of Lucretia and Judith, from designs by Peter Flötner of Nürnberg. The marks are Z.P.W.Z. Probably Swiss, Zürich, second half of 16th century
3. Tankard with cover, embossed, the sides containing oval medallions with allegorical figures. French, 16th century. Perhaps François Briot's work. Ht. 7¼", diam. 4⅞"



BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM

ECCLESIASTICAL AND DOMESTIC PEWTER UTENSILS, 16TH–18TH CENTURY

1. Holy-water bucket, English, *c.* 1500; said to have been dug up in Whitechapel
2. Salt cellar, English, *c.* 1660. Ht. 2.9″
3. Pyx and pair of candlesticks. The pyx is South German, Regensburg work, 18th century. The marks are P, with crossed keys. The candlesticks are pewter, with iron prickers, Flemish, 16th century; from a church in Belgium

PEWTER

BY COURTESY OF (1, 2, 3, 5) THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM, (4, 6) CHARLES G. J. PORT

17TH CENTURY PEWTER

1. Candlestick. Pewter. English, late 17th century. Height 4.8 in.
2. Cup, Pewter, cast in relief. English, early 17th century. Height 7.3 in.
3. Candlestick, Pewter, bearing arms of the Pewterers' Company and maker's name, William Granger, English, dated 1616
4. German guild flagon, 17th century
5. Canister with cover. Lead, square, impressed on each of the sides with George and the dragon. German, 16th century. Height 9½", 5¼" square
6. German guild cup, 17th century

FRENCH AND GERMAN PEWTER PLATES AND SALVERS

1. Large salver, "Temperantia" dish, cast in relief, by François Briot of Lorraine, *c.* 1580–90, signed F.B. The plate is decorated with figures of Minerva and the seven arts, the four elements and Temperance in the centre. (*See* Plate II., fig. 1, for ewer.)
2. Large salver cast in relief and set with a flagon of Limoges enamel. The band of ornament on the outer rim shows scenes from the parable of The Prodigal Son. French, 1550–70. Diam. 17 11/16″
3. Two plates cast in relief: (a) Mark, the arms of Nürnberg, with the initials I.H. South German, dated 1628. (b) Mark, the arms of Nürnberg with the initials B.O. South German, dated 1619

ENGLISH PEWTER DISH

Charles II. dish, second half of 17th century, engraved in the centre with the royal arms encircled by the garter, with supporters; surmounted by a helmet, crowned, and having above it a lion and the initials C.R. Beneath is the royal motto, "Dieu et mon droit." Along the inner rim is the inscription, "Vivat Rex Carolus Secundus, Beati Pacifici 1662." This plate was presented by a member of the royal family, possibly by George III., to Lord Onslow, in 1765. Diam. 22"

water vessels (*bénitiers*), crosses and crucifixes, chrismatories and altar candlesticks. In England efforts are now being made to revive the use of pewter for altar furniture; the difficulty formerly presented by the softness of the metal and its liability to denting seems likely to be overcome by a method of hardening.

In domestic life pewter played an important part for many centuries in the past. In England its use is recorded in the 13th century. Edward I. is said to have owned over 300 vessels of pewter. The Pewterers' Company of the City of London had already been in existence for more than a century and a half when Edward IV. in 1473 presented its first charter granting the right of assay. London was not the only place of manufacture; pewter was produced in several other towns, among them being York, Newcastle, Exeter and Bristol. Although in great favour with the nobility and even with royalty in those days, its use soon became secondary to that of silver and with the middle classes it took the same place as silver among the wealthy.

In Elizabethan days Harrison relates that it had attained a high degree of popularity. The old men of his village, he says, had told him of "the exchange of vessels, as of treen platters" into pewter, and wooden spoons into silver or tin. "For so common were all sorts of treen stuff in old time that a man should hardly find four pieces of pewter in a good farmer's house . . . whereas in my time . . . will the farmer think his gains very small . . . if he have not . . . a fair garnish of pewter on his cupboard, with so much more in odd vessel going about the house." The craft of the pewter had obviously reached its zenith at that time, and its popularity continued for at least the two following centuries. Tankards, measures, plates and salvers were produced, the forms following those of silver but with the minimum of decoration, as was fitting for such a metal. Engraving is used at times; the Victoria and Albert museum, London, possesses two large dishes of the time of Charles II. decorated with arms and large flowers and fruit executed in a kind of zig-zag engraving, and a set of plates and dishes of the following century engraved with figure subjects in Hogarthian style. The use of pewter declined during the 19th century, although employed for candlesticks, teapots, spoons and other domestic utensils; its manufacture survives still for tankards and measures such as are needed in inns and refreshment houses. The *Art Nouveau* (*q.v.*), movement in the opening years of the present century witnessed an endeavour to revive the manufacture of pewter.

In France pewter is found in the 14th century in the form of drinking vessels, plates and salt-cellars, as well as cooking pots for the kitchen. Companies of pewterers existed in various towns, and the trade was flourishing and vigorous. In the 16th century highly ornamented pieces are found, such as those associated with the name of François Briot, the greatest of French pewterers. His well-known Temperantia salver and ewer are covered with ornament in relief. On the ewer are figures of the cardinal virtues, while on the dish are figures of Minerva and the seven arts, with the four elements. A figure of Temperance occupies the central boss, while the whole of the remaining surface is filled with relief ornament. A medallion portrait of Briot appears on the reverse of the dish. Another salver of similar character shows scenes from the story of the Prodigal Son on the outer rim in relief; two inner borders of strapwork, masks, and other ornament surround a central enamelled boss. Fine examples are preserved in the Cluny museum, Paris. Much good pewter was produced during the 17th and 18th centuries. At the end of the 19th century several craftsmen produced good decorative pewter worthy of the older traditions of the art, and following the style of the 16th century workers.

Germany had an established industry of pewter at Augsburg and Nuremberg in the 14th century, Belgium and Holland perhaps earlier; Switzerland must have been working about the same time, as well as Russia and the Scandinavian countries. There is a greater variety of vessels and a wider application of usefulness than in England or Scotland. The treatment of pewter in relief is much more common, and it may easily be imagined how pewter found a natural home with the wood-panelled German or Swiss room for its setting. A pewter cistern and basin often of fanciful shape was a necessary adornment of the Swiss sideboard, while German hostels afforded much in the way of tankards and other drinking vessels. Some German pieces appear to have been purely ornamental, as for example the plates with portraits of emperors in relief or with medallions of Bible scenes. Caspar Enderlein of Nuremberg imitated the designs of the French pewterer, François Briot, and produced a copy of his Temperantia dish. An unusual treatment of tankards shows a wooden vessel inlaid with pewter scrollwork, while in others the pewter is inlaid with brass.

In Germany and Switzerland are found the enormous cups and flagons which formed the treasures of local trade guilds and similar institutions. Standing cups are as much as three feet in height, and one at least is known approaching four feet. They were frequently surmounted by a figure representing the trade to which they belonged, and a number of labels or medallions hanging from the upper part recorded the names of masters of the guild. Flagons were of capacious dimensions. Perhaps the place of honour may be accorded to an unusually noble example in the Victoria and Albert museum, London, of rather more than 20 in. in height. Round the upper and lower part of the body is a band of plaques of graceful emblematical figures taken from the designs of the well-known German ornamentist, Peter Flötner of Nuremberg. This flagon is Swiss work and dates from the 16th century. In recent years pewter has been produced in Germany at Nuremberg, Crefeld and Munich.

In America pewter was much used in the early colonial households. Some is found dating from the 17th century; but the period which marked its greatest production was the 100 years between 1750 and 1850. Boston appears to have been a main centre of manufacture. Every kind of utensil was made which was in any way requisite for domestic purposes. Some few pieces were produced for church use. Its appearance at a considerably later period than in Europe, and its persistence when other materials were available, prove its great popularity and the hold that it retained upon American taste long after it had ceased to interest the European.

In China, Korea and Japan the manufacture of pewter was known over 1,000 years ago and has continued until the present day. Much was produced in the 17th and 18th centuries, the shapes following those of bronze and porcelain; engraving was frequently added as an enrichment. Pewter was used and still is for rim-mounts of boxes and for decorative inlay. (*See* also DRINKING VESSELS; METAL; BRONZE AND BRASS; LEAD IN ART; SILVERSMITHS' AND GOLDSMITHS' WORK; TIN; COPPER.)

PFAFF, JOHANN FRIEDRICH (1765–1825), German mathematician, was born on Dec. 22, 1765 at Stuttgart. He studied at Göttingen and Berlin.

From 1788 to 1810 Pfaff was professor of mathematics in Helmstedt; from 1810 till his death, April 21, 1825, he held the chair of mathematics at Halle. His researches bore chiefly on the theory of series, to which he applied the methods of the so-called combinatorial school of German mathematicians, and on the solution of differential equations. His two principal works are *Disquisitiones analyticae maxime ad calculum integralem et doctrinam serierum pertinentes* (4to., vol. i., Helmstedt, 1797) and a memoir on partial differential equations in *Abh. d. Berl. Acad.* (1814–1815). His method of integrating partial differential equations of the first order with any number of variables led Jacobi to introduce the term "Pfaffian problem."

PFALZBURG: *see* PHALSBOURG.

PFEIFFER, IDA LAURA (1797–1858), Austrian traveller, daughter of a merchant named Reyer, was born at Vienna

on Oct. 14, 1797. In 1820 she married Dr. Pfeiffer, a lawyer of Lemberg, who subsequently incurred official persecution and was reduced to poverty. In her later life Mme. Pfeiffer devoted her limited means to extensive travel. Her last journey was in 1846 to Madagascar, where she became involved in a plot to overthrow the government, and was expelled from the country. She died at Vienna on Oct. 27, 1858.

Her travels are described in *Reise einer Wienerin in das Heilige Land* (Vienna, 1843); *Reise nach dem Skandinavischen Norden und der Insel Island* (Pest, 1846); *Eine Frauenfahrt um die Welt* (Vienna, 1850); *Meine Zweite Weltreise* (Vienna, 1856); *Reise nach Madagascar* (Vienna, 1861, with a biography by her son).

PFLANZER-BALTIN, KARL, Freiherr von, Austro-Hungarian general, was born at Pecs in Hungary in 1855. On the outbreak of the World War he was charged with the defence of Transylvania, but when the Russians at this period crossed the Carpathians, Pflanzer-Baltin, with an improvised division threw himself on this enemy. After fighting with varying success in the southern part of Eastern Galicia and in the Bukovina, the VII. Army under his command was driven back by Brussilov's offensive in June 1916, whereupon he was relieved of his command. In the summer of 1918, entrusted with the command on the Albanian front which was yielding before the attack of the Entente army, Pflanzer-Baltin won back, after a brief and powerful attack, the old positions southwards of Fjeri and Berat.

PFLEIDERER, OTTO (1839–1908), German Protestant theologian, was born at Stetten near Cannstadt in Württemberg on Sept. 1, 1839. From 1857 to 1861 he studied at Tübingen under F. C. Baur; and afterwards in England and Scotland. He then entered the ministry, became *repetent* at Tübingen, and for a short time held a pastorate at Heilbronn (1868). In 1870 he became chief pastor and superintendent at Jena and soon afterwards professor ordinarius of theology, but in 1875 he was called to the chair of systematic theology at Berlin, having made his name by his *Der Paulinismus*, published in 1873 (2nd ed., 1890; Eng. trans., *Paulinism*, 2 vols., 1873, etc.). Other important works are: *Das Urchristentum, seine Schriften und Lehren, in geschichtlichem Zusammenhang beschrieben* (1878; enl. ed. 1902; Eng. trans. 1906); *The Development of Theology since Kant, and its Progress in Great Britain since 1825* (1890), written for publication in England; *Religionsphilosophie auf geschichtlichen Grundlage* (1878; Eng. trans., *The Philosophy of Religion on the Basis of its History*, 1886–1888). *Die Entstehung des Christentums* (1905; Eng. trans., 1906); *Religion und Religionen* (1906; Eng. trans., 1907); and *Die Entwicklung des Christentums* (1907). Pfleiderer was Hibbert lecturer in London in 1885, and Gifford lecturer at Edinburgh in 1894. He died on July 18, 1908. In New Testament criticism Pfleiderer belonged to the school of F. C. Baur, but showed a greater disposition to compromise than the early Baur school.

PFLÜGER, EDUARD (1829–1910), German physiologist, was born in Hanau and studied under Müller and du Bois Reymond at Bonn. In 1868 he founded the *Archiv für die gesamte Physiologie*, and ten years later opened the new Institute of Physiology at Bonn. His *Untersuchungen über die Physiologie des Electrotonus* (1859) marked the beginning of his life-long researches on metabolism, embryology and respiration. He experimented with cross-fertilization of the eggs of different species of frogs and became interested in the cleavage in the development of the eggs. He was able to show that the seat of respiration is not in the blood or lungs, but in the tissue.

PFORTA or **SCHULPFORTA,** formerly a Cistercian monastery dating from 1140, and now a German public school. It is in the Prussian province of Saxony, on the Saale, 2 m. S.W. of Naumburg. The remains of the monastery include the 13th century Gothic church, recently restored, the Romanesque chapel (12th century) and other buildings now used as dormitories, lecture rooms, etc. There is also the Fürstenhaus, built in 1573. Schulpforta was one of the three *Fürstenschulen* founded in 1543 by Maurice duke, and later elector, of Saxony, the two others being at Grimma and at Meissen. Pforta passed to Prussia in 1815.

PFORZHEIM, a town of Germany, in the republic of Baden, at the confluence of the Nagold and the Enz, on the margin of the Black Forest, 19 m. S.E. of Karlsruhe by rail. Pop. (1925) 78,859. Pforzheim is of Roman origin. From about 1300 to 1565 it was the seat of the margraves of Baden. It was taken by the troops of the Catholic League in 1624, and was destroyed by the French in 1689. It has the old palace of the margraves of Baden, and the Schlosskirche, the latter an edifice of the 12th–15th centuries. Pforzheim is the chief centre in Germany for the manufacture of gold and silver ornaments and jewellery.

PHAEDO, Greek philosopher, founder of the Elian school, was a native of Elis, born in the last years of the 5th century B.C. In the war of 401–400 between Sparta and Elis he was enslaved in Athens. He became a pupil of Socrates, who conceived a warm affection for him. It appears that he was intimate with Cebes and Plato, and he gave his name to one of Plato's dialogues. Athenaeus relates, however, that he resolutely declined responsibility for any of the views with which Plato credits him, and that the relations between him and Plato were the reverse of friendly. Aeschines also wrote a dialogue called *Phaedo*. Shortly after the death of Socrates Phaedo returned to Elis, where his disciples included Anchipylus, Moschus and Pleistanus, who succeeded him. Subsequently Menedemus and Asclepiades transferred the school to Eretria, where it was known as the Eretrian school and is frequently identified (*e.g.*, by Cicero) with the Megarians. The doctrines of Phaedo are not known, nor is it possible to infer them from the Platonic dialogue. His writings, none of which are preserved, were in the form of dialogues.

See Wilamowitz, *Hermes*, xiv. 189 *seq.*

PHAEDRA, in Greek legend, daughter of Minos and Pasiphaë. With her sister Ariadne she was carried off by Theseus to Athens, and became his wife. On the way to Eleusis she met Hippolytus, (*q.v.* for the rest of the legend).

PHAEDRUS, Roman fabulist, was by birth a Macedonian and lived in the reigns of Augustus, Tiberius, Gaius and Claudius. According to his own statement (prologue to book iii.), not perhaps to be taken too literally, he was born on the Pierian mountain, but he seems to have been brought at an early age to Italy, for he mentions that he read a verse of Ennius as a boy at school. According to the heading of the chief ms. he was a slave and was freed by Augustus. He incurred the wrath of Seianus, the powerful minister of Tiberius, by some supposed allusions in his fables, and was brought to trial and punished. We learn this from the prologue to the third book. The dates of publication of the fables are unknown, but Seneca, writing between A.D. 41 and 43 (*Consol. ad. Polyb.* 27), knows nothing of Phaedrus, and it is probable that he had published nothing then. His work shows little or no originality; he simply versified in iambic trimeters the fables current in his day under the name of "Aesop," interspersing them with anecdotes drawn from daily life, history and mythology. He tells his fable and draws the moral with businesslike directness and simplicity; his language is terse and clear, but thoroughly prosaic. His Latin is correct, and, except for an excessive and peculiar use of abstract words, shows hardly anything that might not have been written in the Augustan age. From a literary point of view Phaedrus is inferior to Babrius, and to his own imitator, La Fontaine; he lacks the quiet picturesqueness and pathos of the former, and the exuberant vivacity and humour of the latter.

In the middle ages Phaedrus exercised a considerable influence through the prose versions of his fables which were current, though his own works and even his name were forgotten. Of these prose versions the oldest existing seems to be that known as the "Anonymus Nilanti," so called because first edited by Nilant at Leiden in 1709 from a ms. of the 13th century. It approaches the text of Phaedrus so closely that it was probably made directly from it. But the largest and most influential of the prose versions of Phaedrus is that which bears the name of *Romulus*. It contains 83 fables, is as old as the 10th century, and seems to have been based on a still earlier prose version, which, under the name of "Aesop," and addressed to one Rufus, may have been made in the Carolingian period or even earlier. The collection of fables in the Weissenburg (now Wolfenbüttel)

ms. is based on the same version as *Romulus.* These three prose versions contain in all 100 distinct fables, of which 56 are derived from the existing and the remaining 44 presumably from lost fables of Phaedrus. Several scholars have tried to restore these lost fables by versifying the prose versions.

The collection bearing the name of *Romulus* became the source from which, during the second half of the middle ages, almost all the collections of Latin fables in prose and verse were wholly or partially drawn.

The first edition of the five books of Phaedrus was published by Pithou at Troyes in 1596. In the beginning of the 18th century there was discovered at Parma a ms. of Perotti (1430–80), archbishop of Siponto, containing 64 fables of Phaedrus, of which some 30 were new. These new fables were first published at Naples, by Cassitto in 1808, and afterwards (much more correctly) by Jannelli in 1809 Both editions were superseded by the discovery of a much better preserved ms of Perotti in the Vatican, published by Angelo Mai in 1831 For some time the authenticity of these new fables was disputed, but they are now generally accepted, and with justice, as genuine fables of Phaedrus They do not form a sixth book, for we know from Avianus that Phaedrus wrote five books only, but it is impossible to assign them to their original places in the five books. They are usually printed as an appendix

Since Pithou's edition in 1596 Phaedrus has been often edited and translated, among the editions may be mentioned those of Burmann (1718 and 1727), Bentley (1726), Schwabe (1806), Berger de Xivrey (1830), Orelli (1832), Eyssenhardt (1867), L. Muller (1877), Rica (1885), and above all those of L Havet (Paris, 1895) and J. P. Postgate (*Phaedri Fabulae Aesopiae,* Script. Class Bibl Oxon 1920) For the mediaeval versions of Phaedrus and their derivatives *see* L Roth, in *Philologus,* i 523 *seq ;* E. Grosse, in *Jahrb f class Philol*, cv (1872); and especially the learned work of Hervieux, *Les Fabulistes latins depuis le siècle d'Auguste jusqu'à la fin du moyen âge* (Paris, 1884), who gives the Latin texts of all the mediaeval imitators (direct and indirect) of Phaedrus, some of them being published for the first time. (J P P.; X)

PHAER (or PHAYER), **THOMAS** (1510?–1560), English translator of Virgil, was educated at Oxford and at Lincoln's Inn He published in 1535 *Natura brevium,* and in 1543 *Newe Boke of Presidentes* He says on the title-page of his version of the *Aeneid* that he was "solicitor to the king and queen's majesties, attending their honourable council in the marches of Wales" He settled at Kilgarran in Pembrokeshire, and combined the study of medicine with his legal practice He wrote several medical works, and was admitted M D of Oxford in 1559 He contributed to Sackville's *Mirrour for Magistrates,* "Howe Owen Glendower, being seduced by false prophecies, toke upon him to be Prince of Wales" In 1558 appeared *The Seven First Bookes of the Eneidos of Virgil converted into English Meter.* He left his task incomplete. The translation was finished by Thomas Twyne in 1584 Phaer was the first to attempt a complete English version of Virgil, the earlier renderings of Surrey and Gawain Douglas being fragmentary

PHAËTHON, in Greek mythology, was the son of Helios, the sun-god, and the nymph Clymene (Gr *phaethōn,* shining, radiant). He persuaded his father to let him drive the chariot of the sun across the sky, but he lost control of the horses, and driving too near the earth scorched it. To save the world from utter destruction Zeus killed Phaëthon with a thunderbolt He fell to earth at the mouth of the Eridanus, a river of northern Europe (identified in later times with the Po), on the banks of which his weeping sisters, the Heliades, were transformed into poplars and their tears into amber. The story is most fully told in the *Metamorphoses* of Ovid (i 750, ii 366, and Nonnus, *Dionysiaca,* xxxviii). The fall of Phaethon is a favourite subject, especially on sarcophagi, as indicating the transitoriness of human life.

See G. Knaack, "Quaestiones phaethonteae," in *Philologische Untersuchungen* (1885); Wilamowitz-Mollendorff and C Robert in *Hermes,* xviii. (1883); Frazer's *Pausanias,* ii. 59, which gives interesting parallels; S. Reinach, *Revue de l'hist. des religions,* lviii (1908).

PHAETON, a low form of horse-drawn carriage also known as pony phaeton, likewise a high carriage with back to back seats. In the United States (1929) the term is being quite generally applied to an open type automobile body with two fixed seats, four doors, folding top and removable curtains. (*See* TOURING CAR)

PHAGOCYTOSIS is the property possessed by many animal cells of engulfing particles by virtue of their power of amoeboid movement. Primarily this power was directed towards nutrition but in higher organisms it has been developed for different purposes and in pathology at the present day bears a wider meaning. The particle having been englobed, one of three things may happen. (1) If the particle be digestible the cell secretes a digestive fluid, a food vacuole is formed, the particle is gradually dissolved by the secretion and the products absorbed into the cell substance (2) If the particle be indigestible, it is retained within the cell for a time and ultimately discharged The particle englobed may comprise almost any material, but if it is to serve as a food it must be of animal or vegetable origin At the time of ingestion it may be dead or living If living the organism is first killed and then digested or (3) the organism may prove resistant, multiply and finally destroy the cell, when a number of organisms are set free. This is one of the means by which, in the higher organisms, a local infection may become distributed through the organism Digestion within a cell is fermentative; a proteolytic ferment has been prepared from the bodies of amoebae which is active in acid, neutral or especially alkaline media

The study of phagocytosis was largely extended in the elaboration of Metchnikoff's view of the nature of immunity Thus, to take an instance from the sponges, minute organisms, which have penetrated the pores of the sponge are seized by the ciliated or amoeboid cells lining those spaces, and are then killed and digested It is readily understandable that we should find such cells on the external surface of an organism or lining the alimentary tract But in addition there are many fixed or wandering cells within the body in which phagocytic power is retained and markedly developed They remove foreign material or debris which may occur within a tissue For instance, as the result of an injury, inflammatory process, etc , cells and other structures of a tissue are destroyed One of the processes preliminary to repair consists in the removal of the resulting debris, which is effected by phagocytes A similar process is seen with red blood corpuscles which have escaped into a tissue through rupture of capillaries Foreign particles accidentally gaining admission to a tissue are in many cases removed in a similar manner, *e g*, soot particles which have passed through the respiratory surface are largely removed by phagocytes and carried to the bronchial lymphatic glands Very commonly living organisms effect an entrance through wound surfaces, the alimentary surface, etc , and one of the processes employed for their destruction and removal is that of phagocytosis Hence the phagocytes are regarded as scavengers of the tissues

In the above-named instances the phagocytes are chiefly wandering cells brought to the seat of their activity by the blood In any tissue where the process is going on phagocytes have accumulated in large numbers They have been attracted to the damaged area by the chemical process of chemiotaxis At the seat of the change chemical substances are produced (*see* PATHOLOGY) which act upon the phagocytes, causing them to migrate towards the source—positive chemiotaxis The same chemical stimulus in a higher concentration may repel the cells—negative chemiotaxis Instances of this are especially frequent in relation to micro-organisms and phagocytes

Metchnikoff held the view, and supported it by many experiments that immunity and susceptibility to infective disease are essentially matters of phagocytosis but this eclectic view is now obsolete though it is not denied that phagocytosis plays an important part in removing bacterial and other debris rendered harmless by other means (*see* IMMUNITY).

As regards the different varieties of phagocytes, leaving apart the cells lining the alimentary tract, a number of free cells possess amoeboid properties as well as also a number of fixed cells. In the latter category are the nerve cells, the large cells of the spleen

pulp and of lymph glands, certain endothelial cells, the neuroglia cells, and perhaps certain cells of connective tissues. Those of greater phagocytic activity are the large splenic and lymph cells, the neuroglia cells and certain endothelial cells. With regard to the wandering cells some are certainly non-phagocytic, for instance the lymphocytes. The polymorphonuclear, the large hyaline and the eosinophil leucocyte are phagocytic. Metchnikoff therefore divided the phagocytes into two classes—the microphages, comprising the polymorphonuclear and the eosinophil cell, and the macrophages, containing the large hyaline cell, the cell of the splenic pulp, the endothelial cell and the neuroglia cell.

The two principal groups of leucocytes are generally spread throughout the vertebrates. Instances of each kind are found even in the lamprey. Cells which show but small differences from the analogous cells of mammals are found in the alligator.

(T. G. B.)

PHAGOTUS, a curious reed instrument, developed by Afranio Albanesi of Pavia (16th century) from the ancient Serbian bagpipe or piva. It was shaped like the letter H, the upper part of each side pillar containing the sound-producing tubes, pierced with finger-holes, and the wind supply being provided by an attached air-reservoir in the form of a bag, and bellows.

PHALANGER, a name applied to the members of the diprotodont marsupial family *Phalangeridae* (*see* MARSUPIALIA).

Phalangers are small or medium-sized woolly coated animals, with long, often prehensile tails, large claws and opposable, nail-less, first hind-toes. They are nocturnal in habit and feed on fruit, leaves and blossoms, though a few are insect-eaters. Several possess gliding membranes between the fore and hind limbs.

The ring-tailed phalangers (*Pseudochirus*) of Australia and New Guinea are the most generalized forms. Allied to them is the Australian "flying-squirrel" (*Petauroides volans*), ranging from Queensland to Victoria. Another flying genus is *Petaurus*, with several species on the Australian continent, Aru Islands and New Guinea. A third parachuting form is the minute *Acrobates pygmaeus* of East Australia.

BY COURTESY OF THE N Y. ZOOLOGICAL SOCIETY

THE PHALANGER, A MEMBER OF A GROUP OF MARSUPIALS

The cuscuses (*Phalanger*) are arboreal animals, the size of cats. They inhabit the Solomon Islands, ranging thence to the Moluccas and Celebes, being the only Old World marsupials found west of New Guinea. The fur is woolly and the tail prehensile. Nearly allied to these are the Australian forms, of which the brush-tailed phalanger (*Trichosurus vulpecula*), about the size of a small fox, is the best known. Other species are *T. fuliginosus* of Tasmania and *T. canina* of South Queensland and New South Wales.

PHALANX, the name, in Greek history of the arrangement of heavy-armed infantry in a single close mass of spearmen (Gr. φάλαγξ, of unknown origin) (*see* ARMY: *History*).

PHALARIS, tyrant of Acragas (Agrigentum) in Sicily, *c.* 570–554 B.C. He was entrusted with the building of the temple of Zeus Atabyrius in the citadel, and took advantage of his position to make himself despot (Aristotle, *Politics*, v. 10). Under his rule Agrigentum seems to have attained considerable prosperity. He supplied the city with water, adorned it with fine buildings, and strengthened it with walls. On the northern coast of the island the people of Himera elected him general with absolute power, in spite of the warnings of the poet Stesichorus (Aristotle, *Rhetoric*, ii. 20). According to Suidas he succeeded in making himself master of the whole of the island. He was at last overthrown in a general rising headed by Telemachus, the ancestor of Theron (tyrant *c.* 488–472), and burned in his brazen bull.

After ages have held up Phalaris to infamy for his excessive cruelty. In his brazen bull, invented, it is said, by Perillus of Athens, the tyrant's victims were shut up and, a fire being kindled beneath, were roasted alive, while their shrieks represented the bellowing of the bull. Perillus himself is said to have been the first victim. There is hardly room to doubt that we have here a tradition of human sacrifice in connection with the worship of the Phoenician Baal (Zeus Atabyrius) such as prevailed at Rhodes. The Carthaginians carried away a brazen bull from Agrigentum to Carthage but it was restored by Scipio.

Later tradition represented Phalaris as a naturally humane man and a patron of philosophy and literature. Plutarch, though he takes the unfavourable view, mentions that the Sicilians gave to the severity of Phalaris the name of justice and a hatred of crime. (Suidas, *s.v.;* Diod. Sic. ix. 20, 30, xiii. 90, xxxii. 25; Polybius vii. 7, xii. 25; Cicero, *De Officiis*, ii. 7, iii. 6.)

The letters bearing the name of Phalaris (148 in number) are now chiefly remembered for the crushing exposure they received at the hands of Richard Bentley in his controversy with the Hon. Charles Boyle, who had published an edition of them in 1695. The first edition of Bentley's *Dissertation on Phalaris* appeared in 1697, and the second edition, replying to the answer which Boyle published in 1698, came out in 1699. Bentley proved conclusively that the letters were written by a sophist or rhetorician (possibly Adrianus of Tyre, died *c.* A.D. 192) hundreds of years after the death of Phalaris. Suidas admired the letters, which he thought genuine and in modern times, before their exposure by Bentley, they were thought highly of by some (*e.g.*, Sir William Temple in his *Essay on Ancient and Modern Learning*), though others, as Politianus and Erasmus, perceived that they were not by Phalaris. The latest edition of the *Epistles* is by R. Hercher, in *Epistolographi graeci* (1873), and of Bentley's Dissertation by W. Wagner (with introduction and notes, 1883); *see* especially R. C. Jebb, *Life of Bentley* (1882).

PHALAROPE, the name given to birds of the genus *Phalaropus*, of which there are three species. The phalaropes are allied to the sandpipers (*q.v.*), from which they differ in their swimming habits and the lobed membranes that fringe their feet and by the close nature of the lower plumage. They are aquatic birds, spending the winter on the open sea. The male is less brightly coloured than the female and performs the duties of incubation. The red-necked phalarope (*P. hyperboreus*) breeds in the Hebrides and Ireland but the group as a whole is an Arctic one. One species, *P. wilsoni*, is exclusively American, the others extend also to Europe.

PHALLICISM or **PHALLISM,** an anthropological term applied to that form of worship in which adoration is paid to the generative function symbolized by the phallus, the male organ (from Gr. φαλλός). The same principle is at the root of the nature worship of Asia Minor, whose chief deity, the Great Mother of the Gods (*q.v.*), is the personification of the earth's fertility: similarly in India worship is paid to divine mothers; the phallus is called *linga* or *lingam*, with the female counterpart called *yoni;* the *linga* symbolizes the generative power of Siva, and is a charm against sterility. The rites classed together as *Sakti puja* represent the adoration of the female principle. Phallic emblems are found in many parts of the world. The tendency, however, to identify all obelisk-like stones and tree trunks, together with rites like circumcision, as remains of phallic worship, has met with much criticism, and the best modern view is that phallicism never developed into an organized cult, *e.g.*, Robertson Smith, *Religion of the Semites*, 3rd ed., pp. 456 and 688.

PHALSBOURG, a town of France, in the department of Moselle, stands on a plateau (1,080 ft.) above the main road from Saverne to Nancy and Metz, 25 m. N.W. of Strasbourg by rail. Pop. (1926) 1,269. The principality of Phalsbourg, of which this town was the capital, originally a part of Luxembourg, afterwards belonged in turn to the bishop of Metz, the bishop of Strasbourg and the duke of Lorraine, and passed to France in 1661 The town commands the passes of the Vosges, and was strongly fortified by Vauban in 1680. Of these fortifications only the Porte de France and the Porte d'Alsace remain.

PHALTAN, a native state of India, in the central division of Bombay, ranking as one of the Satara jagirs. Area, 397 sq.m.; pop. (1921), 43,286. The town of Phaltan is 37 m. north-east of Satara; pop. (1921), 8,929.

PHANARIOTES, a name derived from Phanar, the chief Greek quarter at Stamboul, where the oecumenical patriarchate is situated, and applied to those members of families resident in the Phanar quarter who between the years 1711 and 1821 were appointed hospodars of the Danubian principalities; that period of Moldo-Wallachian history is also usually termed the Pha-

nariote epoch. The active part taken by the Greek princes in the revolt of 1820–21 induced the Porte to revert to the appointment of native princes.

PHANIAS, of Eresus in Lesbos, Greek philosopher and historian, important as an immediate follower of and commentator on Aristotle, came to Athens *c.* 332 B.C., and joined his compatriot, Theophrastus, in the Peripatetic school. His *Analytica, Categoriae* and *De interpretatione,* which were either paraphrases or critical commentaries, seem to have added little to Aristotle's own writings. Alexander of Aphrodisias refers to a work πρὸς Διόδωρον, and Athenaeus quotes from another treatise, *Against the Sophists* He and Theophrastus also carried on the physical investigations of Aristotle; Athenaeus frequently quotes from a work on botany which manifests great care in definitions and accuracy of observation. The chief of his historical works were the *Prytaneis Eresii,* which was either a history of his native place or a general history of Greece arranged according to the period of the Eresian magistracy and works on the *Tyrants of Sicily* and on tyranny in general, which are frequently quoted on questions of chronology (*e g.,* by Plutarch, Suidas, Athenaeus) To the history of Greek literature he contributed works on the poets and on the Socratics, both of which are quoted.

PHANTASMAGORIA, a name invented by a certain Philipstal in 1802 (from Gr φάντασμα, phantasm, apparition, and ἀγορά, assembly) for a show or exhibition of optical illusions produced by means of the projecting lantern (*see* LANTERN). The word has since been applied to any rapidly or strikingly changing scene, or disordered phantasy.

PHARAOH (Par'oh), the Hebraized title of the king of Egypt (*q v*), in Egyptian Per-'o, Pheron in Herodotus represents the same. Its combination with the name of the king, as in Pharaoh-Necho, Pharaoh-Hophra, is in accordance with contemporary native usage the name of the earlier Pharaoh Shishak (Sheshonk) is rightly given without the title. In hieroglyphic a king bears several names preceded by distinctive titles In the IVth Dynasty there might be four of the latter. (1)  identifying him with the royal god Horus, the name is commonly written in a frame  representing the façade of a building, perhaps a palace or tomb, on which the falcon stands (2)  connecting him with the vulture and uraeus goddesses, Nekhabi and Buto of the south and north (3)  a hawk on the symbol of gold, signifying the victorious Horus (4)  the old titles of the rulers of the separate kingdoms of Upper and Lower Egypt, to be read *stni,* "butcher(?)" and *byti,* "beekeeper(?)" The personal name of the king followed (4), and was enclosed in a cartouche  apparently symbolizing the circuit of the sun which alone bounded the king's rule. Before the IVth Dynasty the cartouche is seldom found the usual title is (1), and (3) does not occur In the Vth Dynasty the custom began of giving the king at his accession a special name connecting him with the sun· this was placed in the cartouche after (4), and a fifth title was added. (5)  Si-rē, "son of the Sun-god," to precede a cartouche containing the personal name The king was briefly spoken of by his title *stni* (*see* 4), or *ḥnm-f,* "his service," or *Ity,* "liege-lord" These titles were preserved in the sacred writing down to the latest age An old term for the royal palace establishment and estate was Per-'o, "the Great House," and this gradually became the personal designation of Pharaoh. (F LL. G)

PHARISEES, a sect of the Jews first mentioned by Josephus, (Ant. xiii., 5, 9). Their activity extended over a period of three centuries (from *c.* 135 B C.—A.D. 135). They first emerged as an organized party in the reign of John Hyrcanus and were active down to the time of Hadrian. We may assume that the Pharisees occupied a position of considerable influence and power during the reign of John Hyrcanus (135–105 B C). Later, in the reign of Alexander Jannaeus (104–78 B C.) they appear to have quarrelled with the Maccabaean ruler (who, it must be remembered, functioned as high priest as well as king) and the quarrel lasted some time. The breach was healed in the reign of his widow Salome Alexandra (78–69 B.C.) During the New Testament period the Pharisees, as is evident from the pages of the New Testament, played a dominating part in Jewish communal life.

Their general aim was to develop and deepen the work of the earlier *Ḥasidīm* in making the *Torah* the accepted rule of life for the mass of the Jewish people Their work was astonishingly successful They made the synagogue a permanent and widespread institution of Jewish life Here in the weekly assemblages the lections were read and expounded to the people; the synagogue prayers were developed and made familiar. They also organized a system of elementary religious instruction

Origin of the Name.—Of the various explanations of the name, the view of Lauterbach is most plausible, that the term (which means "separated" or "expelled") is due to an actual event, viz. the expulsion of the lay teachers from the priestly Sanhedrin It must be remembered that during the Persian period of the Post-Exilic epoch the schools which perpetuated the teaching of the law were priestly in character and the actual teachers were themselves priests These earlier *Sopherim* were also responsible for the actual transmission of the text. The system lasted on till the earlier part of the Greek period Then the earlier simplicity and self-contained character of the Jewish community began to break down under the influence of Greek conditions This applied also to the teaching of the law to the people "Laymen arose who had as much influence among the people and with the government as the High-Priest, and they became leaders." These laymen were practically the Pharisaic party who were able to force some of their party into the priestly Sanhedrin Later a crisis arose in the Sanhedrin and the lay leaders were apparently expelled—hence the name Pharisees As is well known, the Pharisees stood for the oral law as well as for the written, and one of their chief preoccupations was to deduce arguments for linking up popular custom with the written text of the Pentateuch They were thus led to develop an ingenious system of exegesis which in course of time resulted in the development of a vast hermeneutical literature

In order to estimate Pharisaism aright during its active period it is necessary to remember that it was sharply divided into warring sects and schools. These are probably not exhausted by the rival schools of Hillel and Shammai; and the polemic of Jesus in the Gospels was primarily directed not against the party as a whole, but against one section of it, an extreme wing of the followers of Shammai who were open to the charge of formalism and hypocrisy. It is probable that the Shammaites were in the ascendent at this time; later, after A D 70, the milder peace-loving school of Hillel predominated. Pharisaism was the dominant factor in the development of orthodox Judaism, which assumed a more or less permanent form in the Rabbinical system Its main interest was to bring the sanctions of religion into this life This tendency also appears in its Messianic doctrine, which it has impressed on all parts of the synagogue liturgy Its Messiah is not the transcendental and heavenly figure of some of the apocalyptists, but a purely human son of David *See* G F. Moore, *Judaism;* Art "Pharisees" in *Enc Rel and Ethics* (G H B)

PHARMACOLOGY. In English-speaking countries, and by the majority of German writers, the term pharmacology is applied to the study of the action of chemical substances (as apart from foods) on all kinds of animals, from bacteria up to man; it is, in fact, a comparative study of the action of chemical bodies on invertebrate and vertebrate animals

Pharmacology is a branch of biology; it is also closely connected with pathology and bacteriology, for certain drugs produce structural as well as functional changes in the tissues, and in germ diseases the peculiar symptoms are caused by foreign substances (toxins) formed by the infective organisms present in the body The effects of many of these toxins bear a close resemblance to the action of certain well-known drugs, as in the case of tetanus toxin and strychnine, and are studied by the same methods

The rapid growth of the science of pharmacology has been one of the most striking features of the development of the science

of medicine during the twentieth century.

Organic Chemistry.—The only substances available for medical use a century ago were certain inorganic salts and crude vegetable extracts. The development of organic chemistry provided therapeutics with purified active principles of the crude vegetable extracts, and thus the use of crude preparations of unknown strength was replaced to a large extent by the use of chemical substances of known composition. Organic chemistry rendered a still more important service to pharmacology with the synthesis of organic compounds by which the number of substances available for use in therapeutics was increased indefinitely.

The anaesthetics, ether (1846) and chloroform (1847), were the first synthetic organic compounds to be used extensively in medicine. Twenty years later the first synthetic hypnotic, chloral hydrate, was introduced, and about 1885 the coal tar antipyretics, acetanilide and antipyrin, were discovered. Since then hundreds of new and valuable synthetic drugs have been discovered.

Salvarsan.—The discovery by Ehrlich in 1910 of salvarsan (*q.v.*), a potent remedy for syphilis, established a new method of research which has since yielded other results of great importance and promises to produce even greater successes.

In his search for a substance which would kill the infectious organism of syphilis (*q.v.*), the *Treponema pallidum,* without injuring the patient, Ehrlich started with the knowledge that allied organisms, the trypanosomes, were killed by certain dyes and organic arsenic compounds. Not content with a random examination of the known compounds, he determined quantitatively which types of compounds were the most satisfactory for his purpose and then got new compounds prepared according to a definite plan. He made a systematic examination of a long series of organic arsenic compounds, determining in each case the minimal dose of the drug which would cure an animal infected with trypanosomes (minimal curative dose) and the maximal dose which the animal could tolerate (maximal tolerated dose). He termed the ratio:—

$$\frac{\text{(maximal tolerated dose)}}{\text{(minimal curative dose)}}$$

the therapeutic index, and sought for a drug with the highest possible therapeutic index. The compound salvarsan or arsenobenzole was the 606th arsenic preparation investigated, and in 1910 it was introduced as a remedy for syphilis. Two years later, Ehrlich introduced neosalvarsan or novarsenobenzole, which has to a large extent replaced salvarsan in the treatment of syphilis (*see* VENEREAL DISEASES). Ehrlich's brilliant success stimulated an intensive investigation of the action of organic metallic compounds upon diseases due to infections by animal parasites.

New Methods.—A number of important new methods of treatment have been discovered. Intramuscular injections of bismuth salts have been found to be of value in the treatment of cases of syphilis which are refractory to the organic arsenicals. Salts of antimony also have been found to have important new therapeutic actions. A century ago the production of subacute antimony poisoning by large doses of tartar emetic was a routine treatment for a very large number of diseases, but the revolt against the "heroic" methods of treatment of disease, in the middle of last century led to tartar emetic being almost abandoned as a therapeutic agent. The drug was discovered to possess the new and important therapeutic action of acting like arsenic as a specific disinfectant for animal parasites (*see* HOOKWORM). Intravenous injections of antimony salts have been found of great value in treating various diseases due to trypanosomal infection, and also have been found to cure the disease bilharziasis (*q.v.*).

Perhaps the most important internal disinfectant to be discovered is the compound "Bayer 205," a derivative of the dye trypan blue. This substance has a powerful action both in preventing and relieving the trypanosomal disease sleeping sickness (*q.v.*), the worst scourge of tropical Africa.

Mollgaard showed recently that an organic compound of gold, sodium aurithiosulphate, named "sanocrysin" can produce very remarkable curative effects, in a certain proportion of cases of tuberculosis (*q.v.*), but is equally capable of producing deleterious effects, and therefore great care is needed in its administration.

Antiseptics.—The special conditions of World War surgery made the discovery of powerful wound disinfectants an urgent problem, and a number of new disinfectant compounds of great activity were discovered, for example the dye "acriflavine," and the quinine derivatives "vuzin" and "optochin" (*see* ANTISEPTICS). Although the synthesis of the alkaloid quinine has not yet been effected, nevertheless its chemical structure is known, and it is possible to modify the structure of the alkaloid and thus produce new compounds. Vuzin and optochin are two quinine derivatives which differ from quinine in having a far more potent disinfectant action on bacteria. Another important new wound disinfectant is chloramine-T, an organic chlorine compound which acts by slowly liberating chlorine. The disinfection of the kidney and the bladder is another important problem in which advances recently have been made. A new organic compound termed hexyl resorcinol appears to be a very powerful urinary disinfectant.

Use of Active Principles.—Most of the advances mentioned hitherto have depended upon the discovery of new synthetic organic compounds of greater potency than any known hitherto, but cures for other diseases have been discovered by substituting purified active principles for crude vegetable extracts.

Ipecacuanha has been known for more than a century to benefit amoebic dysentery, but the administration of the drug by mouth was limited by its action as an emetic. Sir Leonard Rogers showed in 1912 that subcutaneous injections of the alkaloid emetine, the chief active principle present in ipecacuanha, usually produced a rapid cure in cases of amoebic dysentery (*see* DYSENTERY).

Similarly, it has been known for many years that leprosy (*q.v.*) is often benefited by administration of Chaulmoogra oil, but it was found impossible to administer large doses of this oil by mouth on account of its irritant properties. Organic chemists isolated from Chaulmoogra oil certain complex fatty acids named hydnocarpic and chaulmoogric acids, which were believed to be the chief active principles present in the oil. Sir Leonard Rogers in India and Heiser in the Philippines introduced the method of injecting preparations of these purified fatty acids intravenously or intramuscularly and obtained remarkable curative effects even in the cases of leprosy of many years' duration (*see* LEPROSY). The most striking recent successes of pharmacology have been achieved in the cure of infectious diseases, because in most other serious diseases some vital organ has received irreparable damage, which drugs may alleviate but cannot cure.

Anaesthetics and Hypnotics.—Important progress has, however, been made in the discovery of drugs needed to produce certain temporary alterations in the functions of the body. General anaesthetics are perhaps the most important group of drugs of this class. In 1924 and 1925 acetylene and ethylene were tried as substitutes for nitrous oxide, but at present it is doubtful whether the new gases will prove superior to nitrous oxide.

Many drugs produce some very useful action but have in addition some highly undesirable side action. Cocaine (*q.v.*), for example, is an excellent local anaesthetic, with the grave disadvantage of sometimes producing dangerous effects on the brain. Of the large number of local anaesthetics, which have been synthesised in the hope of producing some complete substitute for cocaine, Novocaine is one of the best known and can replace cocaine completely for many but not for all purposes. Since 1910 a number of new compounds of great potency as local anaesthetics have been discovered, and cocaine may soon be superseded.

Similarly, a host of new and very potent hypnotics have been synthesised in the hope of finding a reliable hypnotic which will not produce a habit, and is perfectly safe. Unfortunately, not much advance has been made in this field. In a few cases important new uses have been discovered for drugs which have been known for many years, such as the discovery in 1918 that quinidine, one of the alkaloids present in Cinchona bark or Jesuit's bark, can cure the important disorder of the heart known as auricular fibrillation. (*See* CINCHONA, ALKALOIDS OF.)

Physiological Features.—The accurate analysis of the mode of action of drugs of well-established reputation has in certain cases greatly increased their value, making it possible to increase their dosage with safety and thus ensuring that sufficient of the

drug is given to produce the physiological effect desired. The administration of digitalis in heart disease is a case where considerable improvements in technique of this character have been effected in recent years.

The study of the actions of extracts of the glands of internal secretion (*see* ENDOCRINOLOGY) is a field common to physiology and pharmacology. In 1886 it was shown that the two diseases myxoedema and cretinism, due to deficiency of the thyroid secretion, and previously considered completely incurable, could be cured by the simple remedy of administering dried thyroid gland by the mouth. In 1922 Banting obtained an extract from the pancreas, which he termed insulin (*q.v.*), and which he proved would relieve the disease of diabetes mellitus (*q.v.*).

There are peculiar difficulties attending the study of the secretions of the endocrine glands. Active principles have been obtained from the parathyroid glands and the ovaries which also promise to be of value as agents for substitution therapy, where the normal secretions of these organs are deficient. Substances have been obtained from other endocrine organs which have no certain value as agents for substitution therapy but are drugs with powerful and interesting pharmacological actions. One such substance, adrenalin, was discovered in 1896, and has been found of great value in producing constriction of small arteries and thus acting as a haemostatic.

Extracts of the posterior lobe of the pituitary gland produce a rise of blood pressure and constriction of plain muscle and since 1916 this extract has been brought into therapeutic use, and is now very extensively used to cause contraction of the uterus, and thus to accelerate childbirth and to prevent the disastrous complication known as post-partum haemorrhage.

Vitamins.—The vitamins (*q.v.*) are biological products which have important pharmacological actions. They are unstable bodies of unknown chemical composition which are present in minute amounts in a large variety of fresh foods, but usually are absent in preserved foods. Several vitamins exist, and a regular supply of all of them is essential to normal development and health. Scurvy and rickets are two examples of diseases caused by vitamin lack. Lemon juice has been known for more than a century to be a specific cure for scurvy, and biochemists have now succeeded in concentrating the vitamins of lemon juice so that a child suffering from infantile scurvy can be given the vitamin equivalent of 20 lemons in a single day. Similarly, cod liver oil has long been recognized as a cure for rickets, and the vitamin of cod liver oil has also been prepared in concentrated form.

Parasitology.—The disease-producing parasites are of two classes, firstly the animal parasites such as the trypanosomes, and secondly the vegetable parasites, the bacteria. Very remarkable successes have attended the preparation of internal disinfectants for the animal parasites, and cures have been found for a number of the worst diseases that afflict mankind; in particular, cures have been discovered for a number of very serious tropical diseases (*q.v.*). Less striking success has attended the endeavour to find disinfectants that will kill bacteria infecting the body, but a certain amount of progress has been made, and any advance in this field is of the greatest importance to the inhabitants of temperate climates, because most of the worst infectious diseases of the temperate zone are bacterial in origin.

BIBLIOGRAPHY.—The most important work for general reference is A. Heffter, *Handbuch der Experimentelle Pharmakologie*, 3 vol. (1920); *see* also A. R. Cushny, *Pharmacology and Therapeutics*, 8th ed. (1924); W. E. Dixon, *Manual of Pharmacology*, 6th ed. (1925); A. J. Clark, *Applied Pharmacology*, 2nd ed. (1926); T. Sollinann, *Manual of Pharmacology*, 3rd ed. Philadelphia, 1926 (bibl.); H. H. Meyer and R. Gottlieb, *Experimental Pharmacology*, 2nd ed. in English, Philadelphia, 1926 (bibl.); E. Poulsson, *Text-book of Pharmacology and Therapeutics*, London, 1923.

PHARMACOPOEIA, a book containing directions for the identification of simples and the preparation of compound medicines, and published by the authority of a government or of a medical or pharmaceutical society. The first work of the kind published under government authority appears to have been that of Nuremberg in 1542.

In England until 1617 such drugs and medicines as were in common use were sold by the apothecaries and grocers. In that year the apothecaries obtained a separate charter, and it was enacted that no grocer should keep an apothecary's shop. The preparation of physicians' prescriptions was thus confined to the apothecaries, upon whom pressure was brought to bear to make them dispense accurately, by the issue of a pharmacopoeia in 1618 by the College of Physicians of London, and by the power which the wardens of the apothecaries received in common with the censors of the College of Physicians of examining the shops of apothecaries within 7 m. of London and destroying all the compounds which they found unfaithfully prepared. Between 1618 and 1851, 13 editions of the *London Pharmacopoeia* were issued, each tending towards simplification and elimination of many ridiculous and highly compound medicines that had been in vogue for 2,000 years.

The first *Edinburgh Pharmacopoeia* was published in 1699 and the last in 1841; the first *Dublin Pharmacopoeia* in 1807 and the last in 1850.

The preparations contained in these three pharmacopoeias were not all uniform in strength. In consequence of this inconvenience and danger the Medical Act of 1858 ordained that the General Medical Council should cause to be published the *British Pharmacopoeia*, which should be a substitute throughout Great Britain and Ireland for the separate pharmacopoeias. The first *British Pharmacopoeia* was published in 1864. Since then revised editions have been brought out periodically, physicians and pharmacists being consulted in their compilation. But each new edition requires several years to carry out numerous experiments for devising suitable formulae, so that the current Pharmacopoeia can never be quite up to date. This difficulty has hitherto been met by the publication of such non-official formularies as Squire's *Companion to the Pharmacopoeia* and Martindale's *Extra Pharmacopoeia*, recording all new remedies and their preparations, uses and doses.

National pharmacopoeias now exist in the following countries: Austria, Belgium, Chile, Denmark, France, Germany, Great Britain, Greece, Holland, Hungary, India, Japan, Mexico, Norway, Portugal, Russia, Spain, Sweden, Italy, Switzerland, the United States, Venezuela, Rumania, Finland, Argentina and Servia.

The French *Codex* has probably a more extended use than any other pharmacopoeia outside its own country, being, in connection with Dorvault's *L'Officine*, the standard for druggists in a large portion of Central and South America; it is also official in Turkey. It contains about 1,250 drugs and preparations, or double the average of other modern pharmacopoeias.

Some difficulty has arisen since the passing of the Adulteration of Food and Drugs Act concerning the use of the Pharmacopoeia as a legal standard for the drugs and preparations contained in it. It has been held in the Divisional Courts (*Dickins* v. *Randerson*) that the Pharmacopoeia is a standard for official preparations asked for under their pharmacopoeial name. But for many drugs and chemicals not in the Pharmacopoeia there is no standard of purity that can be used under the Adulteration of Food and Drugs Act. An important step towards supplying this need has been taken by the publication under the authority of the Council of the Pharmaceutical Society of Great Britain of the *British Pharmaceutical Codex*, in which the characters of and tests for the purity of many non-official drugs and preparations are given as well as the character of many glandular preparations and antitoxins that have come into use in medicine, but have not yet been introduced into the Pharmacopoeia.

An International Pharmacopoeia.—Attempts have been made by international pharmaceutical and medical conferences to settle a basis on which an international pharmacopoeia could be prepared, but so far without result. (*See* PHARMACY.) On the other hand, a project for an imperial pharmacopoeia which should be adapted to the general and local requirements of all parts of the British Empire has met with better success. With the aid of the medical and pharmaceutical authorities in each of the seventy administrative divisions of the British Empire an Indian and Colonial addendum to the *British Pharmacopoeia* of 1898 was compiled and published in 1900 in which each article receives official sanction in the countries indicated in the monographs.

Several unofficial universal pharmacopoeias have been pub-

lished in England and in France, which serve to show the comparative strength of parallel preparations in different countries. The greatest stumbling-blocks in the way of uniformity are the tinctures and extracts in which the same name does not always indicate the same thing; thus, extract of aconite signifies an extract of the root in the pharmacopoeias of the United States, Japan and Russia, extract of the leaves in the Danish and Portuguese, inspissated juice of the fresh leaves in the Greek, and alcoholic extract of the root in that of Spain and Italy, and alcoholic extract of the dried leaves in the Chilean pharmacopoeia. It appears probable, however, that the growth of pharmaceutical chemistry will indicate, in time, which of those in use form the most active and trustworthy preparations, while the general adoption of the metric system will lead to clearer approximation of strength than hitherto. Homeopathic and eclectic practitioners as well as dentists have also their special pharmacopoeias.

See Martindale and Westcott, *Extra Pharmacopoeia*, 18th ed. 1924–25, 19th ed. vol i. 1928; *British Pharmaceutical Codex*, London, 1923; *British Pharmacopoeia*, London, 1914; Squire's *Companion to the British Pharmacopoeia*, 19th ed. London, 1916; *Codex medicamentarius Sallieus: Pharmacopée française*, Paris, 1920; *Pharmacopoeia of the United States of America* 10th decennial revision Philadelphia, 1925; *Deutsches Arzneibuch* 6th ed. Berlin 1926. (E. M. Ho.)

PHARMACOSIDERITE, a mineral species consisting of hydrated basic ferric arsenate, $2FeAsO_4 \cdot Fe(OH)_3 \cdot 5H_2O$. Crystals have the form of small, sharply defined cubes of an olive- or grass-green colour, and occur together in considerable numbers on the matrix of the specimens. On account of its cubic form it was early known as "cube ore;" the name pharmacosiderite alludes to the arsenic and iron present (φάρμακον, poison, and σίδηρος, iron). The faces of the cube are striated parallel to one diagonal, and alternate corners may be replaced by faces of a tetrahedron. Natural crystals are sometimes honey-yellow to brown in colour, but this appears to be due to alteration. Pharmacosiderite is a mineral of secondary origin, the crystals occurring attached to gozzany quartz in the upper part of veins of copper ore.

PHARMACY, the art of preparing, preserving and compounding medicines, according to the prescriptions of physicians. The term was first used in this sense in 1597. The International Congresses of Pharmacy, held at intervals from 1865 to 1913, afforded opportunity for the discussion of questions of international importance. Much time and effort were expended in the endeavour to produce an international Pharmacopoeia and to ensure that all medicinal preparations should be the same, no matter in what country they were prescribed. The attempt failed, but it paved the way for the adoption of useful international regulations. (*See* PHARMACOPOEIA.)

International Uniformity.—The congress held in Paris in 1900 recommended that a comparative table should be prepared showing the difference in the strength of medicaments bearing the same name in different pharmacopoeias. This table was considered at a conference of accredited delegates from various nations in Sept. 1902 and a list of preparations was issued upon which agreement as to strength had been reached. An international agreement embodying this list was signed in 1906 by the representatives of 18 nations and, substantially, all the decisions contained in it have been observed in the new issues of the pharmacopoeias of the signatory nations. A similar conference was held in Paris in 1925 to revise some of the decisions of the first conference and to take further steps towards the unification of the pharmacopoeial formulas for potent drugs and their preparations

The 10th international congress held at Brussels in 1910 decided to establish a Fédération Internationale Pharmaceutique for the protection of pharmacy as a profession and as an applied science. The federation was established in 1912 at The Hague with Prof. Van Itallie and Dr. Hofman, the first president and secretary respectively. Twenty-four national societies of pharmacy are now included in it, although Austria, Denmark, Germany, Hungary and Russia have retired since the World War. The Fédération Internationale Pharmaceutique has held meetings annually since 1922.

Modern Pharmacy and Science.—The demands made upon the scientific knowledge and technical skill of the pharmacist have continually increased as shown by successive editions of the British, United States and other pharmacopoeias. The definition of the drugs has become more precise; tests of identity, limits of impurity, methods of assay have been introduced, and the use of the microscope required for the examination of many vegetable drugs. The introduction into medical practice of countless synthetic chemicals, of such organotherapeutical substances as the thyroid gland, pituitrin, etc., and of various vaccines and sera has imposed upon pharmacists the necessity of special study in order to understand them. The same may be said of the X-rays, and of the vitamins, the latter, in an impure form, being used in the form of compressed tablets or of capsules. Hypodermic injections are now commonly supplied sterilised and in ampoules, and the pharmacist must therefore be acquainted with the principles of sterilisation and with the action upon sensitive alkaloids of the heat used and the alkalinity of the glass of which the ampoules have been made.

The Qualifications of the Pharmacist.—In addition, therefore, to a knowledge of chemistry and botany as applied to pharmacy the pharmacist must be an expert microscopist. He must keep himself informed as to the new developments of therapeutics and must be competent to supply such medicines as the physician may prescribe. Disinfection and hygiene also come within his purview. To ensure his competency the Fédération Internationale Pharmaceutique agreed that the following subjects should find a place in the studies of the pharmaceutical student: chemistry (analytical, biological, physiological and pathological), pharmacy (chemical and galenical), pharmacognosy, micrography, toxicology, hygiene, legislation, pharmacology, botany, microbiology, mathematics, crystallography, disinfection, sterilisation and optics.

Modern Developments.—Developments in the treatment of diseases and in the nature and quality of the remedial agents required, which are the outcome of scientific research, have a direct bearing upon pharmacy. Barger, Dale, Carr, Stoll and others have shown that ergot contains two extremely powerful alkaloids, ergotoxine and ergotamine, upon which its activity chiefly depends, accompanied by various amines such as tyroamine and histamine, which possess a subsidiary efficacy. The two alkaloids are soluble in alcohol but insoluble in water and are easily converted into inactive substances from which they can be regenerated. These discoveries opened the way to a preparation of ergot which has proved very satisfactory.

For a long time the group of oxymethylanthraquinone drugs, which includes purgatives such as rhubarb, cascara sagrada, etc., had baffled investigators as the crystalline oxymethylanthraquinones or their glucosides failed to explain, quantitatively at least, the action of the drugs. Maeder has isolated from elder buckthorn bark the glucoside glucorhamnin in which two sugar groups are present. The laxative action of glucofrangulin is such that the amount present in the drug corresponds to the activity of the latter. Probably similar glucosides will be found in other members of the group. Kiefer, working upon Cape aloes, showed that the resins previously considered inactive were, on the contrary, strongly purgative and isolated the substance to which the griping action was due and so made an important step towards a rational preparation of aloes. Bourquelot showed that many enzymes possess a synthetical as well as analytical action and prepared a number of synthetical glucosides and demonstrated the possibility of producing in the laboratory an entirely new class of compounds.

Stabilisation of Drugs.—Pharmacists have long desired to make from drugs preparations which should contain the active constituents in the condition in which they exist in the plant. Goris and Arnould made an important step towards solving this problem by proving that the caffeine in fresh kola nuts exists in combination with kolatin, a combination which is broken up by an oxidase present in the fresh nuts. This oxidase can be rendered inactive by steam or alcohol vapour and the combination then remains unaltered when the nuts are dried and preparations made from them. Such treatment, or "stabilisation," of a drug will probably be extensively adopted.

Medicinal Plants.—During the World War large quantities

of medicinal plants were collected in Great Britain, partly wild, partly cultivated. Attempts to place the cultivation upon a satisfactory footing failed, owing to the difficulty of obtaining assistance for the young industry. In France the Government afforded every aid, and under the direction of Perrot the industry is rapidly growing and much information is being collected as to the effects of soil, manures, etc., necessary to produce the best results. In the United States considerable attention has been devoted to selection experiments with drug plants, and marked progress has been made towards the production of the most suitable strains. The extremely high price of santonin led to a search for other sources of that vermifuge.

Educational System in Great Britain.—The Poisons and Pharmacy Act of 1908 allowed a body corporate, and in Scotland a firm or partnership, to carry on the business of a pharmaceutical chemist or chemist and druggist provided that the business, so far as it related to the keeping, retailing and dispensing of poisons, was under the control of a registered pharmaceutical chemist or chemist and druggist. In the second place powers were given to the Pharmaceutical Society to divide the qualifying examination into two parts and to require candidates for the examination to produce satisfactory evidence that they had received a sufficient preliminary practical training in the subjects of the examination In 1920 the by-laws and regulations necessary for carrying the provisions of the Act of 1908 into effect were drawn up. They came into full force at dates varying from Feb. 1, 1927, to Aug. 1, 1929, and may be briefly summarised as follows:—

Before presenting himself for examination the candidate must have been registered as a student of the Pharmaceutical Society for which purpose he must have passed one of a number of entrance examinations ranging from the junior local examination of Cambridge or Oxford to the matriculation examination of the University of London. After registration he may proceed to the preliminary scientific examination, for which attendance at an approved systematic course of instruction of at least 440 hours in chemistry, botany and physics is necessary. Having passed this, or one of several alternative examinations, he will have to decide whether he will be content with passing the chemist and druggist qualifying examination or aim at the higher qualification by training for the pharmaceutical chemist qualifying examination. In the former case, when giving notice, he must produce a declaration that he has been trained under the direct supervision of a pharmacist in the dispensing and compounding of medicines for 4,000 hours spread over not less than two years in a pharmacy or in the dispensary of a hospital or similar institution approved by the council. He must also have attended an approved systematic course of at least 720 hours in pharmacy, pharmaceutical chemistry, pharmacognosy and forensic pharmacy.

If the candidate elects to proceed from the preliminary scientific examination to the pharmaceutical chemist qualifying examination, then he must be trained for at least 2,000 hours in a pharmacy or hospital and have attended an approved systematic course of at least 1,600 hours in botany, chemistry, pharmacognosy, pharmacy and forensic pharmacy. The statutory examinations in these subjects are conducted by the Pharmaceutical Society.

Thus, whereas in 1920 there was no compulsory curriculum of any kind, the entrant into pharmacy now has to undergo what is practically a two years' approved systematic course of training for the lower qualification and a three years' for the higher; in addition, if he has matriculated, university degrees are open to him. This achievement places the pharmaceutical student in Great Britain on a level with those of most other countries.

Sale of Poisons.—Since the passing of the British Poisons and Pharmacy Act in 1908 the number of substances brought within the range of Part I. of the schedule (those which may not be sold to any person unknown to the seller unless introduced by a person known to both parties and of which the sale must be duly registered) has been much increased. It now includes:

Aconite, aconitine and their preparations; all poisonous alkaloids not specifically named, and their salts and all poisonous derivatives of alkaloids; arsenic and its preparations; atropine and its salts and their preparations; belladonna and all preparations or admixtures (except belladonna plasters) containing 0·1% or more of belladonna alkaloids; cannabis (the dried flowering or fruiting tops of the pistillate plant of *Cannabis sativa*) and the resins prepared therefrom. Cantharides and its poisonous derivatives; coca, any preparation or admixture of, containing 0·1% or more of coca alkaloids; corrosive sublimate; cyanide of potassium and all poisonous cyanides and their preparations; diamorphine (also known as heroin) and all preparations or admixtures containing 0·1% of diamorphine; diethyl-barbituric acid and other alkyl, aryl or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal or by any other trade name, mark or designation; and all poisonous urethanes and ureides; digitalin and all other poisonous constituents of digitalis; ecgonine and all preparations or admixtures containing 0·1% of ecgonine; emetic tartar and all preparations or admixtures containing 1% or more of emetic tartar; ergot of rye and preparations of ergots; lead in combination with oleic acid or other higher fatty acids, whether sold as diachylon or any other designation (except machine-spread plasters), nux vomica and all preparations or admixtures containing 0·2% or more of strychnine; opium and all preparations or admixtures containing 0·2% or more of morphine; picrotoxin; prussic acid and all preparations or admixtures containing 0·1% or more of prussic acid; savin and its oil and all preparations or admixtures containing savin or its oil; strophanthin and all other poisonous constituents of strophanthus; tobacco, any preparations or admixtures of (other than tobacco prepared for smoking and snuff), containing the poisonous alkaloids of tobacco.

By the Dangerous Drugs Act 1920–23 further restrictions have been placed upon the sale of morphine, cocaine, ecgonine, diamorphine, heroin and their respective salts and medicinal opium. Generally stated, these drugs may, with certain exceptions, be supplied only to physicians' prescriptions and a record must be kept of the quantities bought and sold

The Labelling of Poisons Order, which came into force in Great Britain on Jan. 1, 1926, imposed further conditions upon the sale of poisons (whether contained in Part I. or Part II. of the schedule) This Order and the Act under which it is made require that, in general, every preparation containing as an ingredient any poison to which the Pharmacy Act 1868, as amended, applies shall bear on the label a statement of the proportion which such poison bears to the total ingredients of the preparation. The Fédération Internationale Pharmaceutique is endeavouring to formulate a scheme for the uniform treatment of such preparations by all the states included in it (H. G. G.)

THE UNITED STATES

Education.—The total number of pharmacy schools in the United States is between 70 and 80, the majority of which are enrolled in an organization known as the American Association of Colleges of Pharmacy. This organization, since its establishment in 1900 has had a great influence in raising the standards of pharmaceutical education by voluntary co-operation, as there are no national or State laws covering the subject in a general way

Preliminary requirement for entrance to the study of pharmacy is four years of accredited high school work or its equivalent. The minimum course is of three years duration, each year consisting of 32 weeks of college work with certain requirements as to credit hours and curricula. The minimum degree is Graduate in Pharmacy (Ph.G.), which is acceptable as qualifying for registration under most State laws The degree of pharmaceutical chemist (Ph C.) is also given for a somewhat more advanced course, and the degree of Bachelor of Science in Pharmacy (B Sc in Phar) is annually conferred upon many students who voluntarily take a longer and more difficult course, as this degree is usually the minimum educational qualification for official governmental and State positions and for many positions in manufacturing establishments. Post graduate courses leading to the degree of Master of Science in Pharmacy (M Sc in Phar.), and Doctor of Pharmacy (Phar.D) are available for those who wish to continue their studies, particularly with a view of entering research work or the profession of teaching

Beginning with the classes entering the pharmacy colleges in 1932 no student will be accepted for a course less than four years duration, so that by 1936 the minimum course in pharmacy recognized in the United States will be that leading to the degree of Bachelor of Science in Pharmacy.

Registration Requirements.—There is no national examining or registering body in the United States and each State has its own laws applying to the subject. These laws and the procedures growing out of their enforcement have been materially harmonized and rendered more nearly uniform by the National Association of Boards of Pharmacy The majority of the States now require graduation from a recognized college of pharmacy as a necessary

qualification for admission to the examination for registration. In addition to this, all of the States require from two to four years of what is called "drug store experience," a custom dating from the time when a college education in pharmacy was not required.

Laws Affecting Pharmacists.—The laws pertaining to the adulteration of drugs and medicines and the enforcements of legal standards are both State and national in scope. Prior to 1906 there was no Federal law and the States alone controlled the situation. The passage of what is known as the Federal Food and Drugs Act in 1906 greatly strengthened the control of adulteration and misbranding of drugs The Federal law affects only those products which enter interstate commerce and specifically recognizes the standards of the U.S. Pharmacopoeia and the National Formulary as officially governing drugs and medicines. Since 1906 many State laws have been brought into harmony with the provisions of the Federal Act, and as the State laws control intrastate transactions, the entire situation is governed.

Another important act affecting pharmacists in the United States is the Harrison Antinarcotic Act, which is an act giving police power to the United States government in the control of the distribution of habit-forming drugs such as morphine, cocaine, etc. The provisions of this Act require the registration of every physician prescribing certain habit-forming drugs and of every pharmacist dispensing such drugs, as well as control of the manufacturers and jobbers or wholesalers.

Still another act of prime importance affecting pharmacists is the Volstead Act, which provides the legislative regulation for the Eighteenth Amendment to the Constitution of the United States of America, commonly known as the "Prohibition Amendment." This legislation makes the physician and the pharmacist jointly and solely responsible for the dispensing of intoxicating liquors used in the alleviation and cure of disease. A system of registration and of permits, together with numerous regulations and inspections is in constant enforcement by Federal officials, who, as in the Antinarcotic Act, are given police powers in dealing with the situation. Frequent reports are required in connection with the enforcement of both the Antinarcotic and Prohibition laws.

Pharmaceutical Manufacturing and Retailing.—Pharmaceutical manufacturing on a large scale has reached a very high state of efficiency in the United States. This does not take into account the nostrum or so-called "Patent medicine" business, over which no supervising control whatever is exercised, except in the matter of labeling, where the Food and Drugs Act holds the manufacturers of such preparations to strict accountability in connection with claims for composition and curative value. The manufacture of official preparations which a century ago was almost entirely in the hands of retail pharmacists themselves, has almost all been given over to the large scale manufactures. In addition there is a great volume of business in non-secret medicines which physicians are induced to prescribe by name instead of writing a detailed prescription for each patient.

American pharmacy is confronted with a very embarrassing situation in that the professional courses for registration are longer and more exacting and the demand for professional pharmaceutical services seems to be diminishing. This has led to the development of commercialism in pharmacy to a degree not yet experienced in other countries, and the independent pharmacist who desires to maintain his professional status is having a difficult time to hold his own. (C. H. LAW.)

PHARNABAZUS, Persian soldier and statesman, the son of Pharnaces, belonged to a family which from 478 B.C. governed the satrapy of Phrygia on the Hellespont, from its headquarters at Dascylium. Pharnabazus first appears as satrap of this province in 413, when he entered into negotiations with Sparta and began war with Athens After the war he came into conflict with Lysander (*q.v.* *see* also PELOPONNESIAN WAR), who tried to keep the Greek cities under his own dominion, and became one of the causes of his overthrow, by a letter which he sent to the ephors at Sparta.

When in 399 the war with Sparta broke out he again tried to conduct it strenuously. With the help of Conon and Evagoras of Salamis he organized the Persian fleet, and while he was hard pressed on land by Agesilaus he prepared the decisive sea-battle, which was fought in August 394 at Cnidus under his and Conon's command, and completely destroyed the Spartan fleet. He sent support to the allies in Greece, by which the walls of the Peiraeus were rebuilt. But in the war on land he struggled in vain against the lethargy and disorganization of the Persian Empire; and when at last, in 387, in consequence of the embassy of Antalcidas to Susa, the king decided to conclude peace with Sparta and to enter again into close alliance with her, Pharnabazus, the principal opponent of Sparta, was recalled from his command in high honours, to marry Apame, a daughter of the king (Plut. *Artax.* 27).

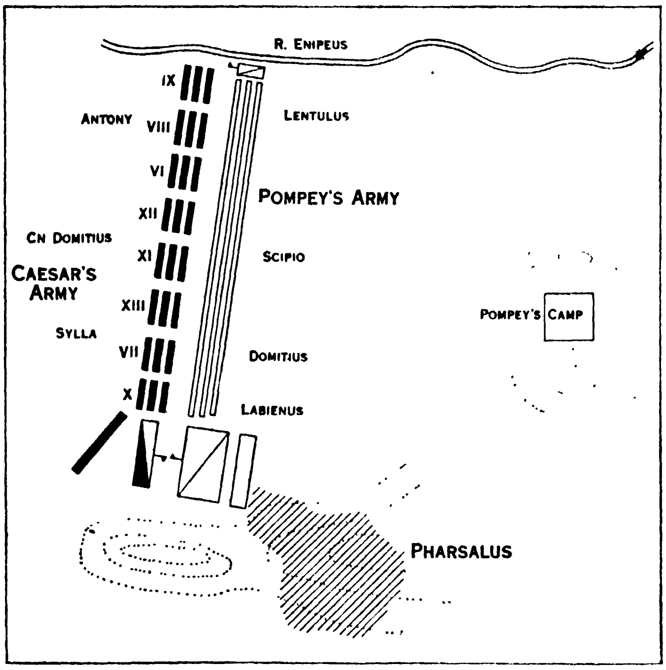
In 385 Pharnabazus was one of the generals sent against Egypt, and in 377 he was ordered to prepare a new expedition against the valley of the Nile. The gathering of the army took years, and when in 373 all was ready, his attempt to force the passage of the Nile failed. A conflict with Iphicrates, the leader of the Greek mercenaries, increased the difficulties; at last Pharnabazus led the army back to Asia. When he died is not known. (ED. M.)

PHARSALUS, BATTLE OF (48 B.C.). The defeat sustained by Julius Caesar at Dyrrachium in May 48 B.C. in no way disheartened him, but it compelled him to change his plan, and that at once. The task before him was a difficult one, namely to retire before a victorious enemy and cross two bridgeless rivers, the Genusus and Apsus. Leaving 15 cohorts and 300 vessels to guard Dyrrachium, on June 3 Pompey set out towards Heraclea whilst Caesar made his way to Aeginium in Thessaly where he was joined by Cn. Domitius and two legions; this brought his force up to nine, some 24,000 men. He moved eastwards and camped north-west of Pharsalus in the plain on the left bank of the Enipeus. There he awaited his enemy whose army numbered 50,000 infantry, 7,000 cavalry and a large number of light troops. Pompey felt certain of victory, but he overlooked the personal factor and forgot that Caesar *was* his army, and that as one writer says: "The whole body was instinct with his purpose." Caesar felt equally certain of success. The battle was fought on June 29.

Pompey planned to hold Caesar's front with his infantry and mass his cavalry, largely outnumbering Caesar's, on his left wing in order to envelop Caesar's right wing and attack it in rear. Pompey's right wing rested on the river Enipeus and was protected not only by the steep banks but by a force of some 600 horsemen, as Caesar saw. It was under the command of Lentulus, and was composed of Cilician and Spanish troops—

good soldiers. His left wing numbered the I. and III. legions and was accompanied by Pompey in person. Scipio held the centre with two Syrian legions and the bulk of the cavalry, slingers and archers, under Labienus were massed on the outer flank of the left wing.

Caesar drew up his legions in three lines of cohorts, four in the first, three in the second and three in the third; his men stood eight deep. On the right he placed the X. legion and on the left the



THE POSITION OF THE ARMIES AT THE BATTLE OF PHARSALUS, MAY 48 B.C. WHEN JULIUS CAESAR DEFEATED THE ARMY OF POMPEY

IX. Antony commanded the left, Sylla the right and Cn. Domitius the centre; he himself took up his position opposite Pompey. Thus far his order of battle was normal, but he had noticed the large force of cavalry massed on his enemy's left. Recognising that this mass was intended to outflank him, he drew up a fourth line of chosen cohorts, taken from the third line, and placed six of these cohorts and his small force of horse on his right, telling them that on their courage would depend the results of the battle. The third line he proposed to hold in reserve, and the first and second he ordered not to charge until he required it to. The trumpets were then sounded, and the battle cry of "Venus Victrix" raised, to which the Pompeians answered: "Hercules Invictus."

Pompey had ordered his men to await the enemy's assault, for he considered that when the two forces clinched his troops would be the fresher; but Caesar realising that this was a sign of weakness ordered his legions forward, trusting as he did to the impetus of the charge inspiring them with courage. Mid-way his men paused to regain breath, then advanced again, and when within range the front rank men hurled their javelins and drawing their swords rushed forward, and the two lines clinched. Immediately Pompey launched his cavalry and archers against his enemy's right flank, driving Caesar's cavalry from the field. Then the fourth line came into play, and in place of casting their javelins they closed on the horsemen with the sword "striking at the horses' breasts, and the men's legs and faces." In spite of their numbers the horsemen turned and fled, and the fourth line falling upon the archers and slingers drove them back, then, wheeling to the left, they struck Pompey's front, now locked in battle, on its flank and rear. At once Caesar galloped to his third line and ordered it to advance. This it did, breaking through Pompey's front. When Pompey saw his cavalry routed, despairing of success, he fled to his camp, possibly to rally the fugitives. The camp was eventually assaulted and taken, whereupon Pompey and 30 horse fled to Larissa and embarked for Egypt, where later on he was assassinated by Ptolemy Auletes, or rather by his tutor the eunuch Photinus, for Ptolemy was but a boy of ten. In this battle Caesar lost 30 centurions and 200 men killed, and Pompey 15,000 killed and 24,000 prisoners. Caesar for political reasons showed great clemency by proclaiming a general pardon. He then organised his prisoners into two new legions and sent them to Asia.

PHARYNGITIS. The pharynx is frequently the seat of a chronic inflammatory condition, usually associated with derangements of the digestive organs, or with syphilis or gout; sometimes it is due to much speaking or to excessive tobacco-smoking —especially of cigarettes. On inspection, the inflamed mucous membrane is seen unduly red and glazed, and dotted over with enlarged follicles. The condition produces irritation and "dryness," with cough and discomfort, which may eventually become chronic. Treatment consists in removing sources of irritation, and in the application of the electric cautery, of astringent lotions or of mild caustic solutions.

PHARYNX, in anatomy, the cavity into which both the nose and mouth lead, which is prolonged into the oesophagus or gullet below, and from which the larynx or air tube comes off below and in front; it therefore serves as a passage both for food and air. The back and sides of the cavity are formed by the three constrictor muscles of the pharynx, each of which overlaps the outer surface of the one above it, and these are lined internally by thick mucous membrane. Above, the pharynx is attached firmly to the base of the skull and the internal pterygoid plates, so that this part cannot collapse, but below the anterior and posterior walls are in contact, and a transverse section of the pharynx is a mere slit.

From the front wall, on a level with the floor of the nose and roof of the mouth, a slanting shelf of muscular and glandular tissue covered with mucous membrane, projects downward and backward into the cavity, and divides it into an upper part or naso-pharynx and a lower or oral pharynx (*see* fig.). This shelf is the *soft palate,* and from the middle of its free border hangs a worm-like projection, the *uvula.* The whole of the front wall of the naso-pharynx is wanting, and here the cavity opens into the nose through the posterior nasal apertures (*see* Olfactory System). On each side of the naso-pharynx, and therefore above the soft palate, is the large triangular opening of the Eustachian tube through which air passes to the tympanum (*see* Ear). Behind this opening, and reaching up to the roof of the naso-pharynx, is a mass of lymphoid tissue, most marked in children, known as the pharyngeal tonsil. This tissue hypertrophies in the disease known as "adenoids."

The oral pharynx communicates with the naso-pharynx behind the free edge of the soft palate. Above and in front it is continuous with the cavity of the mouth, and the demarcation between the two is a ridge of mucous membrane on each side running from the soft palate to the side of the tongue, and caused by the projection of the palato-glossus muscle (anterior pillar of the fauces). About half an inch behind this ridge is another, made by the palato-pharyngeus muscle, which gradually fades away in the side of the pharynx below (posterior pillar of the fauces). Between the two pillars is the fossa (tonsilar sinus) in which the tonsil lies.

The *Tonsil* is an oval mass of lymphoid tissue covered by mucous membrane which dips in to form mucous crypts; externally its position nearly corresponds to that of the angle of the jaw. It is very vascular, deriving its blood from five neighbouring arteries. Below the level of the tonsil the anterior wall of the pharynx is formed by the posterior or pharyngeal surface of the tongue (*q.v.*), while below that is the epiglottis and upper opening of the larynx which is bounded laterally by the aryteno-epiglottic folds (*see* Respiratory System). On the lateral side of each of these folds is a pear-shaped fossa known as the *sinus pyriformis.* Below this the pharynx narrows rapidly until the level of the

lower border of the cricoid cartilage in front and of the sixth cervical vertebra behind is reached; here it passes into the oesophagus, having reached a total length of about five inches.

The mucous membrane of the naso-pharynx, like that of the rest of the respiratory tract, is lined by ciliated columnar epithelium, but in the oral pharynx the epithelium is of the stratified

SAGITTAL SECTION THROUGH MOUTH, TONGUE, LARYNX, PHARYNX, AND NASAL CAVITY, VIEWING THE SECTION SLIGHTLY FROM BELOW

squamous variety. Numerous racemose glands are present (*see* GLANDS; TISSUES), as well as patches of lymphoid tissue especially in childhood. Outside the mucous membrane and separating it from the constrictor muscles is the pharyngeal aponeurosis, which blends above with the periosteum of the base of the skull.

Embryology.—The pharynx is partly formed from the ectodermal stomatodaeal invagination (*see* EMBRYOLOGY and MOUTH) and partly from the fore gut, which is the cephalic part of the entodermal mesodaeum. Up to the fifteenth day (*see* MOUTH), the bucco-pharyngeal membrane separates these structures, and, though no vestiges of it remain, it is clear that the upper and front part of the naso-pharynx is stomatodaeal while the rest is mesodaeal. The five visceral arches with their intervening clefts or pouches surround the pharynx, and the Eustachian tube is a remnant of the first of these. The second pouch is represented in the adult by the tonsilar sinus, and until lately the lateral recess of the pharynx was looked upon as part of the same, but it has now been shown to be an independent diverticulum. The *sinus pyriformis* probably represents that part of the fourth groove from which the lateral lobes of the thyroid body are derived.

The tonsil is formed in the second branchial cleft or rather pouch, for the clefts are largely incomplete in man, about the fourth month; its lymphoid tissue, as well as that elsewhere in the pharynx, is formed from lymphocytes in the subjacent mesenchyme (*see* EMBRYOLOGY), though whether these wander in from the blood or are derived from original mesenchyme cells is still doubtful. The development of the ventral part of the pharynx is dealt with in the articles TONGUE and RESPIRATORY SYSTEM.

Comparative Anatomy.—In the lower, water-breathing vertebrates the pharynx is the part in which respiration occurs. The water passes in through the mouth and out through the gill slits where it comes in contact with the gills or branchiae.

The lowest subphylum of the phylum Chordata, to which the term Adelochorda is sometimes applied, contains a worm-like creature Balanoglossus, in which numerous rows of gill slits open from the pharynx, though Cephalodiscus, another member of the same subphylum, has only one pair of these.

In the subphylum Urochorda, to which the Ascidians or sea-squirts belong, there are many rows of gill slits, as there are also in the Acrania, of which Amphioxus, the lancelet, is the type. In all these lower forms there are no true gills, as the blood-vessels lining the large number of slits provide a sufficient area for the exchange of gases.

In the Cyclostomata a reduction of the number of gill slits takes place, and an increased area for respiration is provided by the gill pouches lined by pleated folds of entodermal mucous membrane; these form the simplest type of true internal gills. In the larval lamprey (Ammocoetes) there are eight gill slits opening from the pharynx, but in the adult (Petromyzon) they are reduced to seven, and a septum grows forward separating the ventral or branchial part of the pharynx from the dorsal or digestive part. Both these tubes, however, communicate near the mouth.

In fishes there are usually five pairs of gill slits, though a rudimentary one in front of these is often present and is called the spiracle. Occasionally, as in Hexanchus and Heptanchus, there may be six or seven slits, and the evidence of comparative anatomy is that fishes formerly had a larger number of gill slits than at present.

In the Teleostomi, which include the bony fishes, there is an external gill cover or operculum.

In the Dipnoi or mud fish the work of the gills is shared by that of the lungs, and in the African form, Protopterus, external gills, developed from the ectodermal parts of the gill slits, first appear. In the tailed Amphibians (Urodela) the first and fifth gill clefts are never perforated and are therefore in the same condition as all the gill clefts of the human embryo, while in the gilled salamanders (Necturus and Proteus) only two gill clefts remain patent. The gills in all the Amphibia are external and of ectodermal origin, but in the Anura (frogs and toads) these are succeeded before the metamorphosis from the tadpole stage by internal gills, which, unlike those of fish, are said to be derived from the ectoderm.

In the embryos of the Sauropsida (reptiles and birds) five gill clefts are evident, though the posterior two are seldom at any time perforated, while in the Mammalia the rudiments of the fifth cleft are no longer found in the embryo, and in man, at all events, none of them are normally perforated except that part of the first which forms the Eustachian tube. It will thus be seen that in the process of phylogeny there is a gradual suppression of the gill clefts beginning at the more posterior ones.

The soft palate is first found in crocodiles as a membranous structure, and it becomes muscular in mammals. The bursa pharyngea and pharyngeal tonsil are found in several of the lower mammals. In the sheep the latter is particularly large.

PHASES. The different luminous appearances presented by the moon (*q.v.*) and several of the planets, the variety of the amount of surface visible from the earth being termed phases.

PHEASANT, the bird, according to legend, introduced by the Argonauts into Europe from the banks of the Phasis (now Rion) in Colchis. Its introduction into England has been attributed, as in the case of so many other species (*e.g.*, the fallow deer, the edible snail, and the Roman nettle), to the Romans, but with

little foundation. This bird, *Phasianis colchicus,* is the type of the family *Phasianidae,* and is reared in England for shooting (*see* SHOOTING). It is distributed in a wild state from the Caspian Sea all over south-east Europe. The male is a handsome bird with brilliant plumage and red wattles; the female protectively coloured in mottled brown. The wings are short; the tail is long. The birds are polygamous; they feed on grain, seeds, shoots, and insects and both fly and run well. The nest is on the ground and 11 or 12 olive-brown eggs are laid. Pheasants will cross with numerous other gallinaceous birds, including the common fowl; the offspring in this case is called a *pero.* The British pheasants have in their blood a mixture of two Chinese species, with white neckrings. This mixture, as well as the pure-bred bird, has been introduced into various parts of U.S.A. and Canada. Reeve's pheasant (*P. reevesi*) from northern China has a very long tail. The golden pheasant (*Chrysolophus pictus*), Amherst's pheasant (*C. amherstiae*) and the silver pheasants (*Gennaeus spp.*) are even more beautiful. They are all Chinese birds and are well known in aviaries. The lovely Argus pheasants (*Argusianus*) of Malacca and Siam may measure 6ft. from the beak to the tail in the male; the secondaries of the wings (which are longer than the primaries) have metallic spots resembling eyes. The monals (*Lophophorus*) inhabit the Himalayas. The peacock pheasants (*Chalcurus* and *Polyplectron*) inhabit Burma, Siam. Indo-China, and the Malay region; the plumage is ornamented with metallic eyespots. The adornments of male pheasants are strikingly displayed in courtship. (*See* COURTSHIP OF ANIMALS.) The so-called Bohemian pheasants are a very rare variety.

PHEIDIAS, son of Charmides, universally regarded as the greatest of Greek sculptors, was born at Athens about 500 B.C. Hegias of Athens was his first master. To his early career belong a chryselephantine Athene for Pellene and a Marathon memorial at Delphi. To this period also belongs the great bronze Athene whose helmet and spear could be seen above the Acropolis buildings far out to sea. An Apollo, found in the Tiber, bears so many of Pheidias's known characteristics that it may be Pheidias's own work (Schrader, in *Jahreshefte,* 1911). If so, it is the only original work by him that we have. Our information as to his later career is fuller, but confusing. We know that he made the colossal Zeus at Olympia; that he controlled the artistic activity at Athens under Pericles, and fell into trouble from Pericles's opponents on charges of peculation, and of sacrilege in representing himself and Pericles on Athene's shield. But the order of these events is obscure. All we know is that the Athene Parthenos was dedicated in 438.

It is important to observe that in resting the fame of Pheidias upon the sculptures of the Parthenon we proceed with little evidence. No ancient writer ascribes them to him, and he seldom, if ever, executed works in marble. What he was celebrated for in antiquity were his statues in bronze or gold and ivory. If Plutarch tells us that he superintended the great works of Pericles on the Acropolis, this phrase is very vague. On the other hand, inscriptions prove that the marble blocks intended for the pedimental statues of the Parthenon were not brought to Athens until 434 B.C., which was probably after the death of Pheidias. And there is a marked contrast in style between these statues and the certain works of Pheidias. It is therefore probable that most, if not all, of the sculptural decoration of the Parthenon was the work of pupils of Pheidias, such as Alcamenes and Agoracritus, working on his designs, rather than their own.

Among the Greeks themselves the two works of Pheidias which far outshone all others, and were the basis of his fame, were the colossal figures in gold and ivory of Zeus at Olympia and of Athena Parthenos at Athens, both of which belong to about the middle of the 5th century. Of the Zeus we have unfortunately lost all trace save small copies on coins of Elis, which give us but a general notion of the pose, and the character of the head. The god was seated on a throne, every part of which was used as a ground for sculptural decoration. His body was of ivory, his robe of gold. His head was of somewhat archaic type; the Otricoli mask which used to be regarded as a copy of the head of the Olympian statue is certainly more than a century later in style. Of the Athena Parthenos two small copies in marble have been found at Athens (*see* GREEK ART, fig. 38), which have no excellence of workmanship, but have a certain evidential value as to the treatment of their original. Other works of Pheidias were the Lemnian Athena, an Apollo Parnopius and an Aphrodite Urania at Elis.

The fine torso of Athena in the École des Beaux Arts at Paris, which has unfortunately lost its head, may perhaps best serve to help our imagination in reconstructing a Pheidian original.

As regards the decorative sculptures of the Parthenon, which the Greeks rated far below their colossus in ivory and gold, *see* the article PARTHENON.

Ancient critics take a very high view of the merits of Pheidias. What they especially praise are his elevated ideas of godhead, and these, the expression of the best religious thought of his time, reacted on the religious conceptions of Greece. A copy of the shield that contained his portrait (the "Strangford" shield) is in the British Museum. Pheidias appears as a vigorous, bald-headed old man.

See Petersen, *Kunst des Phidias* (Berlin, 1873); C. Waldstein, *Essays on the Art of Pheidias* (Cambridge, 1885); Collignon, *Pheidias* (Paris, 1886).

PHEIDON (8th or 7th century B.C.), king of Argos. According to tradition he flourished during the first half of the 8th century B.C. He was a vigorous and energetic ruler and greatly increased the power of Argos. He gradually regained sway over the various cities of the Argive confederacy, the members of which had become practically independent, and (in the words of Ephorus) "reunited the broken fragments of the inheritance of Temenus." His object was to secure predominance for Argos in the north of Peloponnesus. Pheidon assisted the Pisatans to expel the Elean superintendents of the Olympian games and presided at the festival himself. The Eleans, however, refused to recognize the Olympiad or to include it in the register, and shortly afterwards, with the aid of the Spartans, who are said to have looked upon Pheidon as having ousted them from the headship of Greece, defeated Pheidon and were reinstated in the possession of Pisatis and their former privileges. Pheidon is said to have lost his life in a faction fight at Corinth, where the monarchy had recently been overthrown. He made changes in the existing system of weights and measures in the Peloponnese, and his system was in use at Athens before Solon (Arist. *Ath. Pol.* x. 2), but Ephorus' statement that he first coined silver money seems unlikely.

His date is disputed. Pausanias assigns the Olympiad at which he presided to 748, but the balance of modern authority is in favour of the first half of the 7th century.

See Herodotus vi. 127; Ephorus in Strabo viii. 358, 376; Plutarch, *Amatoriae narrationes,* 2; Marmor parium, *ep.* 30; Pollux ix. 83; Nicolaus Damascenus, frag. 41 (in C. W. Müller's *Frag. hist. graecorum,* iii.); G. Grote, *History of Greece,* pt. ii. ch. 4; B. V. Head, *Historia Numorum* (1887); F. Hultsch, *Griechische und römische Metrologie* (1882); G. Rawlinson's *Herodotus,* appendix, bk. i., note 8. On the question of Pheidon's date, *see* J. B. Bury, *History of Greece,* ii. 468 (1902); J. P. Mahaffy, *Problems in Greek History,* ch. 3 (1892); J. G. Frazer's note on Pausanias vi. 22. 2; and especially G. Busolt, *Griechische Geschichte* (2nd ed., 1893), ch. iii. 12. C. Trieber, *Pheidon von Argos* (Hanover, 1880), and J. Beloch, in *Rheinisches Museum,* xlv. 595 (1890), favour a later date, about 580.

PHELPS, EDWARD JOHN (1822–1900), American lawyer and diplomat, was born on July 11, 1822, at Middlebury, Vt. He graduated from Middlebury college in 1840, was a schoolmaster for a year in Virginia and was admitted to the bar in 1843. From 1851 to 1853 he was second controller of the U.S. Treasury, and then practised law in New York city until 1857, when he returned to Burlington. He was one of the founders of the American Bar Association, and was its president in 1880–81.

From 1881 until his death he was Kent professor of law in Yale university. He was minister to Great Britain from 1885 to 1889, and in 1893 served as senior counsel for the United States before the international tribunal at Paris to adjust the Bering sea controversy. He died at New Haven, Conn., on March 9, 1900.

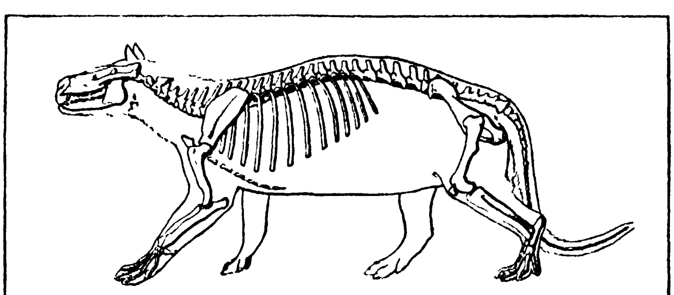
See his *Orations and Essays,* edited by J. G. McCullough, with a "Memoir" by J. W. Stewart (1901); and the memorial address by M. H. Buckham, in *Proceedings of the Vermont Historical Society* (Burlington, Vt., 1901).

PHELPS, SAMUEL (1804–1878), English actor and manager, was born at Devonport on Feb. 13, 1804. He made his first London appearance on Aug. 28, 1837 as Shylock at the Haymarket. After a short season there he was with Macready for about six years at Covent Garden, the Haymarket and Drury Lane successively. In 1844 he became co-lessee of Sadler's Wells Theatre with Thomas L. Greenwood and Mary Amelia Warner (1804–54). Phelps spent 20 years at Sadler's Wells theatre, and raised the house to a leading position in London. Thirty-four of Shakespeare's plays were presented there under his direction. He died on Nov. 6, 1878.

PHENACETIN, a drug crystallizing from water in colourless plates, melting at 135° C. It is soluble in about 70 parts of hot and in about 1,400 parts of cold water. It is prepared by acetylating para-phenetidine, or by heating para-acetylaminophenol and potassium ethyl sulphate with alcoholic soda to 150° C. It is acetyl-*p*-phenetidine, $C_2H_5O{\cdot}C_6H_4{\cdot}NHCOCH_3$. Para-phenetidine is prepared by treating the sodium salt of para-nitrophenol with ethyl iodide, and reducing the nitrophenetole to para-phenetidine or aminophenetole. The yield may be doubled by diazotizing para-phenetidine, coupling with phenol, ethylating and reducing.

Several compounds related to phenacetin have been introduced into medicine. Triphenin is propylphenetidine; lactophenin is lactylphenetidine; pyrantin is para-ethoxyphenyl succinimide, $EtO{\cdot}C_6H_4{\cdot}N[CO{\cdot}CH_2]_2$; salophen or saliphenin is salicylphenetidine; amygdophenin is mandelylphenetidine. In addition, several other derivatives have been suggested which have a greater solubility than phenacetin, *e.g.,* phesin, which is the sodium salt of phenacetinsulphonic acid, apolysin and citrophen (citrophenin), which are citric acid derivatives of para-phenetidin, etc.

Phenacetin is contained in both the British and United States pharmacopoeia, in the latter under the name of acetphenetidin. The dose is 5 to 10 gr. given in cachets or in suspension. When the drug is carelessly made it may contain impurities, producing considerable irritation of the kidneys. The physiological action of phenacetin consists in a sedative action on the sensory tracts of the spinal cord, and a depressant action on the heart, where it tends to paralyse the action of the cardiac muscle. Its chief therapeutic use is as an antineuralgic, and it is of service in migraine, rheumatism of the sub-acute type, intercostal neuralgia and locomotor ataxia.



FROM SCOTT, "LAND MAMMALS OF THE WESTERN HEMISPHERE"

SKELETON OF THE WASATCH CONDYLARTH, IN THE AMERICAN MUSEUM OF NATURAL HISTORY

PHENACODUS, a primitive and generalized hoofed mammal of the Lower Eocene, now extinct. The two best known species are represented by complete skeletons found in the Bighorn basin of Wyoming in 1881. They are of the size respectively of a pig and of a fox, and typically of the family Phenacodontidae of the order Condylarthra.

The teeth of *Phenacodus* are very short-crowned, with low rounded cusps, the dentition unreduced, the premolars smaller than the molars and of simpler pattern. The feet are five-toed but the first and fifth digits are considerably reduced; the small flattened hoofs resemble those of the tapir. The arrangement of the wrist-bones is serial, the upper row directly overlying the lower ones, as in *Hyrax* and the elephant, instead of alternating as with other hoofed animals. The astragalus in the hind foot is like that of Carnivora with distinct neck and convex rounded head. This character distinguishes the Condylarthra from the higher ungulates as the primitive construction of their teeth distinguishes them from the variously specialized ungulate tooth patterns. The brain was small and of inferior structure. (W. D. M.)

PHENAKITE, a mineral consisting of beryllium orthosilicate, Be_2SiO_4, occasionally used as a gem-stone. In general appearance it is not unlike quartz, for which indeed it had been mistaken, and was on this account named from Gr. φέναξ (a deceiver). It occurs as isolated crystals, which are rhombohedral with parallel-faced hemihedrism, and are either lenticular or prismatic in habit. There is no cleavage, the fracture is conchoidal, and the crystals are sometimes perfectly colourless and transparent, but more often greyish or yellowish and only translucent. The hardness is high, being 7·5–8; the specific gravity is 2·98.

Phenakite has long been known from the emerald and chrysoberyl mine on the Takovaya stream, near Ekaterinburg in the Urals, where large crystals occur in mica-schist. It is also found with topaz and microline in the granite of the Ilmen mountains in the southern Urals and of the Pike's Peak region, Colorado. Large crystals of prismatic habit have more recently been found in a felspar quarry at Kragerö, Norway, and clear lenticular crystals are abundant at San Miguel de Piricicaba, Brazil.

For gem purposes the stone is cut in the brilliant form, of which there are two fine examples, weighing 43 and 34 carats, in the mineral collection of the British Museum. The indices of refraction ($\omega = 1{\cdot}6540$, $\epsilon = 1{\cdot}6527$) are higher than those of quartz, beryl or topaz; a faceted phenakite is consequently rather brilliant and may sometimes be mistaken for diamond.

PHENANTHRENE, an aromatic hydrocarbon having the same composition, $C_{14}H_{10}$, as anthracene (*q.v.*) and found with the latter in distillates from coal tar boiling between 270° and 400° C. The crude solid hydrocarbons from this fraction are separated by crystallisation from various organic solvents (alcohol, acetone, carbon disulphide, etc.), phenanthrene being more soluble than anthracene. The former is also less oxidisable than the latter so that chromic acid treatment removes residual anthracene. Phenanthrene (formula I.) is obtained in colourless needles

(I.)   (II.)

or triclinic plates melting at 100–101° C and boiling at 340° C; it exhibits a faint blue fluorescence in solution or when vaporised. Its picrate forms yellow crystals melting at 145° C. Phenanthrene is oxidised by chromic acid to phenanthraquinone (formula II.), obtained in orange needles melting at 198–202° C; it is a typical *ortho*-quinone (*see* QUINONES) and condenses with *ortho*-diamines to form phenazines (*q.v.*). Distilled with soda lime, phenanthraquinone yields diphenyl and by further oxidation the quinone gives diphenic acid. These reactions serve to establish the constitution of the phenanthrene nucleus (I.). This nucleus is present in certain of the opium alkaloids, and when distilled with zinc dust morphine yields phenanthrene. Many attempts have been made, but with little success, to utilise phenanthrene in colour making.

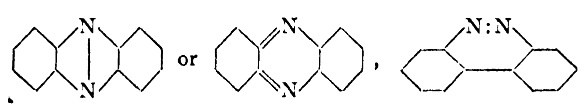
See A. E. Everest, *The Higher Coal Tar Hydrocarbons* (1927).

PHENAZINE, in organic chemistry, the parent substance of many dyestuffs, *e.g.,* the eurhodines, toluylene red, indulines and safranines. (*See* DYES, SYNTHETIC.) It may be obtained by passing aniline vapour over lead oxide, or by the oxidation of dihydrophenazine, which is prepared by heating catechol with orthophenylenediamine. It is also formed when ortho-aminodi

phenylamine is distilled over lead peroxide. It crystallizes in yellow needles which melt at 171° C, and are only sparingly soluble in alcohol. Its formula is $C_{12}H_8N_2$. Sulphuric acid dissolves it, forming a deep red solution. The more complex phenazines, *i.e.*, the naphthophenazines, naphthazines and naphthotolazines, may be prepared by condensing ortho-diamines with ortho-quinones (O. Hinsberg, 1887); by the oxidation of an ortho-diamine in the presence of α-naphthol (O. Witt), and by the decomposition of ortho-anilido (-toluidido-, etc.)-azo compounds with dilute acids. If alkyl or aryl-ortho-diamines be used azonium bases are obtained. The azines are mostly yellow in colour, distil unchanged and are stable to oxidants. They add on alkyl iodides readily, forming alkyl azonium salts.

The symmetrical diaminophenazine is the parent substance of the important dyestuff toluylene red or dimethyldiaminotoluphenazine. It is obtained by the oxidation of orthophenylenediamine with ferric chloride; by oxidizing a mixture of para-aminodimethylaniline and meta-tolylenediamine, toluylene blue, an indamine, being formed as an intermediate product and passing into the red when boiled; and also by the oxidation of dimethylparaphenylenediamine with metatolylenediamine. It crystallizes in orange-red needles and its alcoholic solution fluoresces strongly. It dyes silk and mordanted cotton a fine scarlet. It is known commercially as neutral red. Phenazonium salts are known as safranines. (*See* DYES, SYNTHETIC.)

Phenazone or dibenzopyridazine is an isomeride of phenazine, to which it bears the same relation that phenanthrene bears to anthracene (*qq.v.*). It is formed by reducing diortho-dinitrodiphenyl with sodium amalgam and methyl alcohol. It crystallizes in yellow needles which melt at 156° C. Potassium permanganate oxidizes it to pyridazinetetracarboxylic acid.

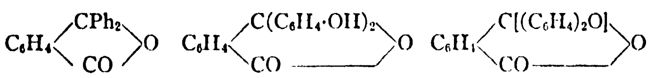


Phenazine Phenazone

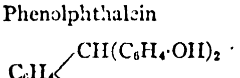
PHENIX CITY, a city of Lee county, Alabama, U.S.A., on the Chattahoochee river, opposite Columbus, Ga. It is on Federal highway 80, and is served by the Central of Georgia railway. Pop. 5,432 in 1920 (85% native white). It is a residential and industrial suburb of Columbus.

PHENOL CONDENSATION PRODUCT: *see* CARBOLIC ACID; BAKELITE.

PHENOLPHTHALEIN, an organic compound of the aromatic series which has two uses: (1) as an indicator for acids and bases in volumetric analysis; (2) as a purgative drug. The phthaleins are prepared by condensing phenols with phthalic anhydride, phenol itself giving rise to phenolphthalein together with a small quantity of fluorane, whilst resorcinol under similar conditions yields fluorescein (*q.v.*). The phthaleins on reduction yield phthalines which are derivatives of triphenylmethane carboxylic acid; thus phenolphthalein itself gives phenolphthaline.



Diphenylphthalide Phenolphthalein Fluorane



Phenolphthaline

Phenolphthalein is obtained when phenol and phthalic anhydride are heated with concentrated sulphuric acid. It crystallizes in colourless crusts (m.p. 250–253° C) and is nearly insoluble in water, but dissolves in dilute solutions of the caustic alkalis with a fine red colour, being reprecipitated from these solutions by the addition of mineral acid. It is to this remarkable colour change that its use as an indicator is due. It dissolves in concentrated caustic alkalis to a colourless solution which probably contains salts of a non-quinonoid character. On fusion with caustic alkali, phenolphthalein yields benzoic acid and para-dihydroxybenzophenone, which shows that in the original condensation the phthalic acid residue has taken the para position to the hydroxyl groups of the phenol.

Fluorane is a by-product of the condensation of phthalic acid and phenol, substitution occurring in the ortho position to the hydroxyl groups of the phenol, so that anhydride formation takes place between these hydroxyl groups. It dissolves in concentrated sulphuric acid with a yellowish-green fluorescence.

Phenolphthalein has extended use as a purgative under such synonyms as purgen, laxoin, laxatol, etc. The official dose is 2 to 5 grains (0·12 to 0·3 grams), but larger doses are given. Phenolphthalein is dissolved in the bile and by the alkali of the intestine, and being irritant to the latter it causes peristalsis. It is partly absorbed and partly excreted by the liver and so acts repeatedly on the intestine, acting for a few days as a mild aperient.

PHENOMENALISM, in philosophy, is a name applied to several different schools of thought which maintain in common that human knowledge (so-called) is confined to phenomena in the broad sense of the term, according to which it denotes generally events or things in space and time. But the schools differ among themselves on the ontological (as distinguished from the epistemological) question relating to the objective source or basis of the phenomena. (1) According to one view it is assumed more or less that there is an objective reality of which the phenomena are the changing appearances, but it is maintained that this ultimate basic reality is beyond the reach of human knowledge, which is limited to the apprehension of appearances adapted to or relative to human powers. In one form or another some such view is maintained by Agnosticism, the critical Philosophy, Empiricism, and Positivism.

(2) Another view is to the effect that there is no permanent substance underlying the ever-changing flux of phenomena; in other words, these ever-changing phenomena are the only reality. This was the view held by Heraclitus among the ancient Greeks, and by Bergson among present-day philosophers, also by others.

(3) Yet a third view would deny the external existence even of phenomena in the ordinary sense of the term (that is, events actually occurring in space and time) and identifies all reality with the mere appearances to or in the mind or mental experiences as such. This view is represented by Shadworth Hodgson, the author of *The Metaphysic of Experience* (1898), and others.

It should be observed that the first kind of phenomenalism (1) is merely epistemological, whereas the other two, (2) and (3), are also ontological. Ontological phenomenalism implies epistemological phenomenalism, but not *vice versa*. *See* METAPHYSICS, and KNOWLEDGE, THEORY OF.

PHENOMENOLOGY denotes a new, descriptive, philosophical method, which, since the concluding years of the last century, has established (1) an a priori psychological discipline, able to provide the only secure basis on which a strong empirical psychology can be built, and (2) a universal philosophy, which can supply an organum for the methodical revision of all the sciences.

I. PHENOMENOLOGICAL PSYCHOLOGY

Present-day psychology, as the science of the "psychical" in its concrete connection with spatio-temporal reality, regards as its material whatever is present in the world as "ego-istic"; *i.e.*, "living," perceiving, thinking, willing, etc., actual, potential and habitual. And as the psychical is known as a certain stratum of existence, proper to men and beasts, psychology may be considered as a branch of anthropology and zoology. But animal nature is a part of physical reality, and that which is concerned with physical reality is natural science. Is it, then, possible to separate the psychical cleanly enough from the physical to establish a pure psychology parallel to natural science? That a purely psychological investigation is practicable within limits is shown by our obligation to it for our fundamental conceptions of the psychical, and most of those of the psycho-physical.

But before determining the question of an unlimited psychology, we must be sure of the characteristics of psychological experience and the psychical data it provides. We turn naturally to our

immediate experiences. But we cannot discover the psychical in any experience, except by a "reflection," or perversion of the ordinary attitude. We are accustomed to concentrate upon the matters, thoughts, and values of the moment, and not upon the psychical "act of experience" in which these are apprehended. This "act" is revealed by a "reflection"; and a reflection can be practised on every experience. Instead of the matters themselves, the values, goals, utilities, etc., we regard the subjective experiences in which these "appear." These "appearances" are phenomena, whose nature is to be a "consciousness-of" their object, real or unreal as it be. Common language catches this sense of "relativity," saying, I was thinking *of* something, I was frightened *of* something, etc. Phenomenological psychology takes its name from the "phenomena," with the psychological aspect of which it is concerned: and the word "intentional" has been borrowed from the scholastic to denote the essential "reference" character of the phenomena. All consciousness is "intentional."

In unreflective consciousness we are "directed" upon objects, we "intend" them; and reflection reveals this to be an immanent process characteristic of all experience, though infinitely varied in form. To be conscious of something is no empty having of that something in consciousness. Each phenomenon has its own intentional structure, which analysis shows to be an ever-widening system of individually intentional and intentionally related components. The perception of a cube, for example, reveals a multiple and synthesized intention: a continuous variety in the "appearance" of the cube, according to differences in the points of view from which it is seen, and corresponding differences in "perspective," and all the difference between the "front side" actually seen at the moment and the "backside" which is not seen, and which remains, therefore, relatively "indeterminate," and yet is supposed equally to be existent. Observation of this "stream" of "appearance-aspects" and of the manner of their synthesis, shows that every phase and interval is already in itself a "consciousness-of" something, yet in such a way that with the constant entry of new phases the total consciousness, at any moment, lacks not synthetic unity, and is, in fact, a consciousness of one and the same object. The intentional structure of the train of a perception must conform to a certain type, if any physical object is to be perceived as there! And if the same object be intuited in other modes, if it be imagined, or remembered, or copied, all its intentional forms recur, though modified in character from what they were in the perception, to correspond to their new modes. The same is true of every kind of psychical experience. Judgment, valuation, pursuit, these also are no empty experiences having in consciousness of judgments, values, goals and means, but are likewise experiences compounded of an intentional stream, each conforming to its own fast type.

Phenomenological psychology's comprehensive task is the systematic examination of the types and forms of intentional experience, and the reduction of their structures to the prime intentions, learning thus what is the nature of the psychical, and comprehending the being of the soul.

The validity of these investigations will obviously extend beyond the particularity of the psychologist's own soul. For psychical life may be revealed to us not only in self-consciousness but equally in our consciousness of other selves, and this latter source of experience offers us more than a reduplication of what we find in our self-consciousness, for it establishes the differences between "own" and "other" which we experience, and presents us with the characteristics of the "social-life." And hence the further task accrues to psychology of revealing the intentions of which the "social life" consists.

Phenomenological-psychological and Eidetic Reductions.—The Phenomenological psychology must examine the self's experience of itself and its derivative experience of other selves and of society, but whether, in so doing, it can be free of all psycho-physical admixture, is not yet clear. Can one reach a really pure self-experience and purely psychical data? This difficulty, even since Brentano's discovery of intentionality, as the fundamental character of the psychical, has blinded psychologists to the possibilities of phenomenological psychology. The psychologist finds his self-consciousness mixed everywhere with "external" experience, and non-psychical realities. For what is experienced as external belongs not to the intentional "internal," though our experience of it belongs there as an experience of the external. The phenomenologist, who will only notice phenomena, and know purely his own "life," must practice an ἐποχή. He must inhibit every ordinary objective "position," and partake in no judgment concerning the objective world. The experience itself will remain what it was, an experience of this house, of this body, of this world in general, in its particular mode. For one cannot describe any intentional experience, even though it be "illusory," a self-contradicting judgment and the like, without describing what in the experience is, as such, the object of consciousness.

Our comprehensive ἐποχή puts, as we say, the world between brackets, excludes the world which is simply there! from the subject's field, presenting in its stead the so-and-so-experienced-perceived-remembered-judged-thought-valued-etc., world, as such, the "bracketed" world. Not the world or any part of it appears, but the "sense" of the world. To enjoy phenomenological experience we must retreat from the objects posited in the natural attitude to the multiple modes of their "appearance," to the "bracketed" objects.

The phenomenological reduction to phenomena, to the purely psychical, advances by two steps: (1) systematic and radical ἐποχή of every objectifying "position" in an experience, practised both upon the regard of particular objects and upon the entire attitude of mind, and (2) expert recognition, comprehension and description of the manifold "appearances" of what are no longer "objects" but "unities" of "sense." So that the phenomenological description will comprise two parts, description of the "noetic" (νόεω) or "experiencing" and description of the "noematic" (νόημα) or the "experienced." Phenomenological experience, is the only experience which may properly be called "internal" and there is no limit to its practice. And as a similar "bracketing" of objective, and description of what then "appears" ("noema" in "noesis"), can be performed upon the "life" of another self which we represent to ourselves, the "reductive" method can be extended from one's own self-experience to one's experience of other selves. And, further, that society, which we experience in a common consciousness, may be reduced not only to the intentional fields of the individual consciousness, but also by the means of an inter-subjective reduction, to that which unites these, namely the phenomenological unity of the social life. Thus enlarged, the psychological concept of internal experience reaches its full extent.

But it takes more than the unity of a manifold "intentional life," with its inseparable complement of "sense-unities," to make a "soul." For from the individual life that "ego-subject" cannot be disjoined, which persists as an identical ego or "pole," to the particular intentions, and the "habits" growing out of these. Thus the "inter-subjective," phenomenologically reduced and concretely apprehended, is seen to be a "society" of "persons," who share a conscious life.

Phenomenological psychology can be purged of every empirical and psycho-physical element, but, being so purged, it cannot deal with "matters of fact." Any closed field may be considered as regards its "essence," its εἶδος, and we may disregard the factual side of our phenomena, and use them as "examples" merely. We shall ignore individual souls and societies, to learn their a priori, their "possible" forms. Our thesis will be "theoretical," observing the invariable through variation, disclosing a typical realm of a priori. There will be no psychical existence whose "style" we shall not know. Psychological phenomenology must rest upon eidetic phenomenology.

The phenomenology of the perception of bodies, for example, will not be an account of actually occurring perceptions, or those which may be expected to occur, but of that invariable "structure," apart from which no perception of a body, single or prolonged, can be conceived. The phenomenological reduction reveals the phenomena of actual internal experience; the eidetic reduction, the essential forms constraining psychical existence.

Men now demand that empirical psychology shall conform to

the exactness required by modern natural science. Natural science, which was once a vague, inductive empiric, owes it modern character to the a priori system of forms, nature as it is "conceivable," which its separate disciplines, pure geometry, laws of motion, time, etc., have contributed. The methods of natural science and psychology are quite distinct, but the latter, like the former, can only reach "exactness" by a rationalization of the "essential."

The psycho-physical has an a priori which must be learned by any complete psychology, this a priori is not phenomenological, for it depends no less upon the essence of physical, or more particularly organic nature.

II. TRANSCENDENTAL PHENOMENOLOGY

Transcendental philosophy may be said to have originated in Descartes, and phenomenological psychology in Locke, Berkeley and Hume, although the latter did not grow up primarily as a method or discipline to serve psychology, but to contribute to the solution of the transcendental problematic which Descartes had posed. The theme propounded in the *Meditations* was still dominant in a philosophy which it had initiated. All reality, so it ran, and the whole of the world which we perceive as existent, may be said to exist only as the content of our own representations, judged in our judgments, or, at best, proved by our own knowing. There lay impulse enough to rouse all the legitimate and illegitimate problems of transcendence, which we know. Descartes' "Doubting" first disclosed "transcendental subjectivity," and his "Ego Cogito" was its first conceptual handling. But the Cartesian transcendental "Mens" became the "Human Mind," which Locke undertook to explore; and Locke's exploration turned into a psychology of the internal experience. And since Locke thought his psychology could embrace the transcendental problems, in whose interest he had begun his work, he became the founder of a false psychologistical philosophy which has persisted because men have not analysed their concept of "subjective" into its twofold significance. Once the transcendental problem is fairly stated, the ambiguity of the sense of the "subjective" becomes apparent, and establishes the phenomenological psychology to deal with its one meaning, and the transcendental phenomenology with its other.

Phenomenological psychology has been given the priority in this article, partly because it forms a convenient stepping-stone to the philosophy and partly because it is nearer to the common attitude than is the transcendental. Psychology, both in its eidetic and empirical disciplines, is a "positive" science, promoted in the "natural attitude" with the world before it for the ground of all its themes, while transcendental experience is difficult to realize because it is "supreme" and entirely "unworldly." Phenomenological psychology, although comparatively new, and completely new as far as it uses intentional analysis, can be approached from the gates of any of the positive sciences: and, being once reached, demands only a re-employment, in a more stringent mode, of its formal mechanism of reduction and analysis, to disclose the transcendental phenomena.

But it is not to be doubted that transcendental phenomenology could be developed independently of all psychology. The discovery of the double relativity of consciousness suggests the practice of both reductions. The psychological reduction does not reach beyond the psychical in animal realities, for psychology subserves real existence, and even its eidetic is confined to the possibilities of real worlds. But the transcendental problem will include the entire world and all its sciences, to "doubt" the whole. The world "originates" in us, as Descartes led men to recognize, and within us acquires its habitual influence. The general significance of the world, and the definite sense of its particulars, is something of which we are conscious within our perceiving, representing, thinking, valuing life, and therefore something "constituted" in some subjective genesis.

The world and its property, "in and for itself," exists as it exists, whether I, or we, happen, or not, to be conscious of it. But let once this general world, make its "appearance" in consciousness as "the" world, it is thenceforth related to the subjective, and all its existence and the manner of it, assumes a new dimension, becoming "incompletely intelligible," "questionable." Here, then, is the transcendental problem; this "making its appearance," this "being for us" of the world, which can only gain its significance "subjectively," what is it? We may call the world "internal" because it is related to consciousness, but how can this quite "general" world, whose "immanent" being is as shadowy as the consciousness wherein it "exists," contrive to appear before us in a variety of "particular" aspects, which experience assures us are the aspects of an independent, self-existent world? The problem also touches every "ideal" world, the world of pure number, for example, and the world of "truths in themselves." And no existence, or manner of existence, is less wholly intelligible than ourselves. Each by himself, and in society, we, in whose consciousness the world is valid, being men, belong ourselves to the world. Must we, then, refer ourselves to ourselves to gain a worldly sense, a worldly being? Are we both psychologically to be called men, subjects of a psychical life, and yet be transcendental to ourselves and the whole world, being subjects of a transcendental world-constituting life? Psychical subjectivity, the "I" and "we" of everyday intent, may be experienced as it is in itself under the phenomenological-psychological reduction, and being eidetically treated, may establish a phenomenological psychology. But the transcendental subjectivity, which for want of language we can only call again, "I myself," "we ourselves," cannot be found under the attitude of psychological or natural science, being no part at all of the objective world, but that subjective conscious life itself, wherein the world and all its content is made for "us," for "me." We that are, indeed, men, spiritual and bodily, existing in the world, are, therefore, "appearances" unto ourselves, parcel of what "we" have constituted, pieces of the significance "we" have made. The "I" and "we," which we apprehend, presuppose a hidden "I" and "we" to whom they are "present."

To this transcendental subjectivity, transcendental experience gives us direct approach. As the psychical experience was purified, so is the transcendental, by a reduction. The transcendental reduction may be regarded as a certain further purification of the psychological interest. The universal is carried to a further stage. Henceforth the "bracketing" includes not the world only but its "souls" as well. The psychologist reduces the ordinarily valid world to a subjectivity of "souls," which are a part of the world which they inhabit. The transcendental phenomenologist reduces the already psychologically purified to the transcendental, that most general, subjectivity, which makes the world and its "souls," and confirms them.

I no longer survey my perception experiences, imagination-experiences, the psychological data which my psychological experience reveals: I learn to survey transcendental experience. I am no longer interested in my own existence. I am interested in the pure intentional life, wherein my psychically real experiences have occurred. This step raises the transcendental problem (the transcendental being defined as the quality of that which is consciousness) to its true level. We have to recognize that relativity to consciousness is not only an actual quality of our world, but, from eidetic necessity, the quality of every conceivable world. We may, in a free fancy, vary our actual world, and transmute it to any other which we can imagine, but we are obliged with the world to vary ourselves also, and ourselves we cannot vary except within the limits prescribed to us by the nature of subjectivity. Change worlds as we may, each must ever be a world such as we could experience, prove upon the evidence of our theories and inhabit with our practice. The transcendental problem is eidetic. My psychological experiences, perceptions, imaginations and the like remain in form and content what they were, but I see them as "structures" now, for I am face to face at last with the ultimate structure of consciousness.

It is obvious that, like every other intelligible problem, the transcendental problem derives the means of its solution from an existence-stratum, which it presupposes and sets beyond the reach of its enquiry. This realm is no other than the bare subjectivity of consciousness in general, while the realm of its investigation

remains not less than every sphere which can be called "objective," which considered in its totality, and at its root, is the conscious life. No one, then, can justly propose to solve the transcendental problem by psychology either empirical or eidetic-phenomenological, without *petitio principii,* for psychology's "subjectivity" and "consciousness" are not that subjectivity and consciousness, which our philosophy will investigate. The transcendental reduction has supplanted the psychological reduction. In the place of the psychological "I" and "we," the transcendental "I" and "we" are comprehended in the concreteness of transcendental consciousness. But though the transcendental "I" is not my psychological "I," it must not be considered as if it were a second "I," for it is no more separated from my psychological "I" in the conventional sense of separation, than it is joined to it in the conventional sense of being joined.

Transcendental self-experience may, at any moment, merely by a change of attitude, be turned back into psychological self-experience. Passing, thus, from the one to the other attitude, we notice a certain "identity" about the ego. What I saw under the psychological reflection as "my" objectification, I see under the transcendental reflection as self-objectifying, or, as we may also say, as objectified by the transcendental "I." We have only to recognize that what makes the psychological and transcendental spheres of experience parallel is an "identity" in their significance, and that what differentiates them is merely a change of attitude, to realize that the psychological and transcendental phenomenologies will also be parallel. Under the more stringent ἐποχή the psychological subjectivity is transformed into the transcendental subjectivity, and the psychological inter-subjectivity into the transcendental inter-subjectivity. It is this last which is the concrete, ultimate ground, whence all that transcends consciousness, including all that is real in the world, derives the sense of its existence. For all objective existence is essentially "relative," and owes its nature to a unity of intention, which being established according to transcendental laws, produces consciousness with its habit of belief and its conviction.

Phenomenology, the Universal Science.—Thus, as phenomenology is developed, the Leibnitzian foreshadowing of a universal ontology, the unification of all conceivable a priori sciences, is improved, and realized upon the new and non-dogmatic basis of phenomenological method. For phenomenology as the science of all concrete phenomena proper to subjectivity and inter-subjectivity, is *eo ipso* an a priori science of all possible existence and existences. Phenomenology is universal in its scope, because there is no a priori which does not depend upon its intentional constitution, and derive from this its power of engendering habits in the consciousness that knows it, so that the establishment of any a priori must reveal the subjective process by which it is established.

Once the a priori disciplines, such as the mathematical sciences, are incorporated within phenomenology, they cannot thereafter be beset by "paradoxes" or disputes concerning principles: and those sciences which have become a priori independently of phenomenology, can only hope to set their methods and premises beyond criticism, by founding themselves upon it. For their very claim to be positive, dogmatic sciences bears witness to their dependency, as branches, merely, of that universal, eidetic ontology, which is phenomenology.

The endless task, this exposition of the universum of the a priori, by referring all objectives to their transcendental "origin," may be considered as one function in the construction of a universal science of fact, where every department, including the positive, will be settled on its a priori. So that our last division of the complete phenomenology is thus: eidetic phenomenology, or the universal ontology, for a first philosophy; and second philosophy as the science of the transcendental inter-subjectivity or universum of fact.

Thus the antique conception of philosophy as the universal science, philosophy in the Platonic, philosophy in the Cartesian, sense, that shall embrace all knowledge, is once more justly restored. All rational problems, and all those problems, which for one reason or another, have come to be known as "philosophical," have their place within phenomenology, finding from the ultimate source of transcendental experience or eidetic intuition, their proper form and the means of their solution. Phenomenology itself learns its proper function of transcendental human "living" from an entire relationship to "self." It can intuite life's absolute norms and learn life's original teleological structure. Phenomenology is not less than man's whole occupation with himself in the service of the universal reason. Revealing life's norms, he does, in fact, set free a stream of new consciousness intent upon the infinite idea of entire humanity, humanity in fact and truth.

Metaphysical, teleological, ethical problems, and problems of the history of philosophy, the problem of judgment, all significant problems in general, and the transcendental bonds uniting them, lie within phenomenology's capability.

Phenomenological philosophy is but developing the mainsprings of old Greek philosophy, and the supreme motive of Descartes. These have not died. They split into rationalism and empiricism. They stretch over Kant and German idealism, and reach the present, confused day. They must be reassumed, subjected to methodical and concrete treatment. They can inspire a science without bounds.

Phenomenology demands of phenomenalists that they shall forgo particular closed systems of philosophy, and share decisive work with others toward persistent philosophy.

PHENOMENON, in ordinary language a thing, process, event, etc., observed by the senses (Gr. *φαινόμενον,* a thing seen, from *φαίνεσθαι,* to appear). Thus the rising of the sun, a thunderstorm, an earthquake, are natural "phenomena." From this springs the incorrect colloquial sense, something out of the common, an event which especially strikes the attention; hence such phrases as "phenomenal" activity. In Greek philosophy phenomena are the changing objects of the senses as opposed to essences (*τὰ ὄντα*) which are one and permanent, and are therefore regarded as being more real, the objects of reason rather than of senses which are "bad witnesses." In modern philosophy the phenomenon is the "thing-in-itself," or the noumenon (*q.v.*) or object of pure thought, but the thing-in-itself as it appears to the mind in sensation (*see* especially KANT; and METAPHYSICS). In this sense the subjective character is of prime importance. Among derivative terms are "Phenomenalism" and "Phenomenology." Phenomenalism is either (1) the doctrine that there can be no knowledge except by phenomena, *i.e.* sense-given data, or (2) the doctrine that all known things are phenomena, *i.e.* that there are no "things-in-themselves." "Phenomenology" is the science of phenomena: every special science has a special section in which its particular phenomena are described. The term was first used in English in the 3rd edition of the *Ency. Brit.* in the article "Philosophy" by J. Robison. Kant has a special use of the term for that part of the *Metaphysic of Nature* which considers motion and rest as predicates of a judgment about things.

PHERECRATES, Greek poet of the Old Attic Comedy, was a contemporary of Cratinus, Crates and Aristophanes. At first an actor, he seems to have gained a prize for a play in 438 B.C.

The only other ascertained date in his life is 420, when he produced his play *The Wild Men.* Like Crates, whom he imitated, he abandoned personal satire for more general themes, although in some of the fragments of his plays we find him attacking Alcibiades and others. He invented a metre, called after him Pherecratean, which occurs in the choruses of Greek tragedies and in Horace.

A considerable number of fragments from his 16 (or 13) plays has been preserved, collected in T. Kock, *Comicorum Atticorum Fragmenta,* i. (1880), and A. Meineke, *Poetarum Comicorum Graecorum Fragmenta* (1855).

PHERECYDES OF LEROS, Greek mythographer, *fl. c.* 454 B.C. He is probably identical with Pherecydes of Athens, although the two are distinguished by Suidas (also by I. Lipsius, *Quaestiones logographicae,* 1886). Numerous fragments of his genealogies of the gods and heroes, variously called Ἱστορίαι, Γενεαλογίαι, Αὐτόχθονες have been preserved (*see* C. W. Müller's *Frag. hist. graec.* vol. i., pp. xxxiv., 70; Jacob, *Frag. d. gr. Historiker* I., p. 58).

See Christ-Schmid, *Geschichte der griechischen Litteratur* (bibl.).

PHERECYDES OF SYROS, Greek philosopher (or rather philosophical theologian), flourished during the 6th century B.C. He was sometimes reckoned one of the Seven Wise Men, and is said to have been the teacher of Pythagoras. With the possible exception of Cadmus (*q.v.*) of Miletus, he was the first Greek prose-writer. He belonged to the circle of Peisistratus at Athens, and was the founder of an Orphic community. He was credited with having originated the doctrine of metempsychosis (*q.v.*), while Cicero and Augustine assert that he was the first to teach the immortality of the soul. Of his astronomical studies he left a proof in the "heliotropion," a cave at Syros which served to determine the annual turning-point of the sun.

In his cosmogonic treatise on nature and the gods, called Πεντέμυχος (Preller's correction of Suidas, who has ἑπτάμυχος from the five elementary principles: aether, fire, air, water, earth), he enunciated a system in which science, allegory and mythology were blended. A fragment of the "sacred marriage" of Zas and Chthonië has been found on an Egyptian papyrus.

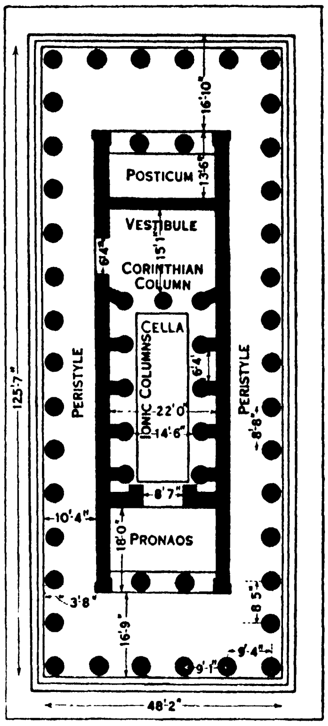
See H. Diels, *Fragmente der Vorsokratiker,* Bd. II. (4th ed., 1922); also O. Kern, *De Orphei, Epimenidis Pherecydis theogoniis* (1888); D. Speliotopoulos, Περὶ Φερεκύδου τοῦ Συρίου (Athens, 1890); T. Gomperz, *Greek Thinkers* (Eng. trs., 1901); B. P. Grenfell, *New Classical Fragments* (1897); H. Weil, *Études sur l'antiquité grecque* (1900).

PHIGALIA or PHIGALEIA (Φιγάλια or Φιγαλεία; mod. *Pavlitsa*), an ancient Greek city on the river Neda in the south-west angle of Arcadia, among some of the highest mountains in the Peloponnesus—Mt. Cotylium and Mt. Elasum.

In 659 B.C. Phigalia was taken by the Spartans, but soon after recovered its independence by the help of the Orasthasians. During the struggle between Achaeans and Aetolians in 221 B.C. it was held by Dorimachus, who left it on the approach of Philip V. of Macedon. In common with other cities of Arcadia, it appears to have fallen into utter decay under Roman rule. Several curious cults were preserved near Phigalia, including that of the fish-tailed goddess Eurynome and the Black Demeter with a horse's head, whose image was renewed by Onatas. No autonomous coins of Phigalia are known. Nothing remains above ground of the temples of Artemis or Dionysus and the works of art which existed in the time of Pausanias. A great part of the city wall remains, 2 m. in circuit built in fine Hellenic masonry, with a large square central fortress with a circular projecting tower.

Not at Phigalia itself, but at Bassae, 5 or 6 m. away, on the slope of Mt. Cotylium is a well-preserved temple of Apollo Epicurius. It commemorates relief from a plague in the 5th century. Pausanias (viii. 41) notes it as (next to that of Tegea) the finest in the Peloponnesus, "from the beauty of its stone and the symmetry of its proportions." It was designed by Ictinus, joint architect with Callicrates, of the Parthenon at Athens. Visited earlier by Chandler, Dodwell, Gell and other English travellers, the temple was explored and measured in 1811–1812 by C. R. Cockerell, the internal sculptured frieze of the cella being found almost perfect. This and other fragments of sculpture are now in the British Museum. The colonnade of the temple has been recently restored by the Greeks.

The temple is of the Doric order, but has an internal arrangement of its cella which is unique. Probably to suit the ground, it lies north and south but the vestibule has a door to the east. It is hexastyle, with fifteen columns on its flanks; thirty-four out of the thirty-eight columns of the peristyle are still standing, with the greater part of their architrave. The internal columns of the cella are very strangely placed, apparently without symmetry, as regards the interior, though they are set regularly opposite the voids in the peristyle.



PLAN OF THE TEMPLE AT BASSAE

With the exception of one at the south end, which is Corinthian, the internal columns are of the Ionic order, and are engaged with the cella-wall, forming a series of recesses, which may have been designed to contain statues. Another peculiarity of this interior is that these columns reach to the top of the cella in one order, not in two as was Doric fashion. These inner columns carried an Ionic entablature, of which the frieze now in the British Museum formed a part. The pediments and external metopes of the peristyle appear to have contained no sculpture, but the metopes within the peristyle on the exterior of the cella had sculptured subjects. The position occupied by the great statue of Apollo is disputed. Cockerell, with much probability, placed it facing the eastern side door, so that it would be lighted by the rising sun. The main entrance is at the northern end through the pronaos, once defended by a door in the end of the cella and a metal screen, of which traces were found on the two columns of the pronaos. There was no door between the posticum and the cella. The general proportions of the fronts resemble those of the Theseum at Athens, except that the entablature is less massive, the columns thicker, and the diminution less. In plan the temple is long in proportion to its width—measuring, on the top of the stylobate, 125 ft. 7 in. by 48 ft. 2 in., while the Theseum (built probably half a century earlier) is about 104 ft. 2 in. by 45 ft. 2 in.

The material is a fine grey limestone (once covered with painted stucco), but the roof-tiles, the capitals of the cella columns, the architraves, the ceilings and the sculpture, are of white marble. The roof-tiles, specially noticed by Pausanias, are remarkable for their size, workmanship, and the beauty of the Parian marble. They measure 2 ft. 1 in. by 3 ft. 6 in., and are fitted together in the most careful and ingenious manner. Unlike those of the Parthenon and the temple of Aegina, the ἁρμοί or "joint-tiles" are worked out of the same piece of marble as the flat ones, for the sake of more perfect fitting and in order to provide greater security against wet.

Traces of painting on various architectural members were found by Cockerell, but they were too much faded for the colours to be distinguished. The designs are the usual Greek patterns—the fret, the honeysuckle, and the egg and dart.

The sculpture is of the greatest interest, as being designed to decorate one of the finest buildings in the Peloponnesus in the latter half of the 5th century B.C.

The frieze, now in the British Museum, is complete; it is nearly 101 ft. long by 2 ft. high, carved in relief on twenty-three slabs of marble $4\frac{1}{2}$ to 5 in. thick. The subjects are the battle of the Lapithae and the Centaurs, and that between the Amazons and the Greeks, the two favourite subjects in Greek art of the best period. They are designed with wonderful fertility of invention, and life-like realism and spirit; the composition is arranged so

as to form a series of diagonal lines or zigzags *M*, thus forming a pleasing contrast to the unbroken horizontal lines of the cornice and architrave. The various groups are skilfully united by some dominant line or action, so that the whole subject forms one unbroken composition.

The relief is very high, more than 3½ in. in the most salient parts, and the whole treatment is quite opposite to that of the Parthenon frieze, which is a very superior work of art to that at Bassae. Many of the limbs are quite detached from the ground; the drill has been largely used to emphasize certain shadows, and in many places, for want of due calculation, the sculptor has had to cut into the flat background behind the figures. From this it would appear that no finished clay-model was prepared but that the relief was sculptured with only the help of a drawing. The point of sight, more than 20 ft. below the bottom of the frieze, and the direction in which the light fell on it have evidently been carefully considered. Many parts, invisible from below, are left comparatively rough. The workmanship throughout is unequal, and the hands of several sculptors can be detected. On the whole, the execution is not equal to the beauty of the design, and the whole frieze is somewhat marred by an evident desire to produce the maximum of effect with the least possible amount of labour—very different from the almost gem-like finish of the Parthenon frieze. Even the design is inferior to the Athenian one; most of the figures are ungracefully short in their proportions, and there is a great want of refined beauty in many of the female hands and faces. It is in the fire of its varied action and its subtlety of expression that this sculpture most excels. The noble movements of the heroic Greeks form a striking contrast to the feminine weakness of the wounded Amazons, or the struggles with teeth and hoofs of the brutish Centaurs; the group of Apollo and Artemis in their chariot is full of grace and dignified power. The marble in which this frieze is sculptured is somewhat coarse and crystalline; the slabs appear not to have been built into their place but fixed afterwards, with the aid of two bronze bolts driven through the face of each.

Of the metopes, which were 2 ft. 8 in. square, only one exists nearly complete, with eleven fragments; the one almost perfect has a relief of a nude warrior, with floating drapery, overcoming a long-haired bearded man, who sinks vanquished at his feet. The relief of these is rather less than that of the frieze figures, and the work is nobler in character and superior in execution.

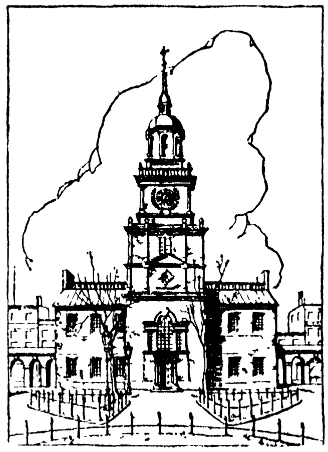
PHILADELPHIA, the Greek name of the ancient Rabbath-Ammon, in Eastern Palestine, commemorating Ptolemy Philadelphus (285–246 B.C.), mod. 'Ammān. Alexander Jannaeus (102–76 B.C.) although lord of the rest of the land east of the Jordan never conquered Philadelphia. With the coming of Pompey (63 B.C.) Philadelphia was made a member of the Decapolis. When Trajan set up the *Provincia Arabia* (A.D. 106) he assigned the town to the new province and Philadelphia advanced with Bostra to greater might and prosperity. Its extensive ruins include a Byzantine basilica, baths, theatre, citadel, temple, etc. (E. Ro.)

PHILADELPHIA, the first city of the State of Pennsylvania, and third in population and manufactures in the United States. It was planned by William Penn and other members of the Society of Friends partly, if not chiefly, as a haven of refuge for persecuted peoples, who like themselves, wished to be guided by the "inner light" of conscience. They called their town Philadelphia (from the Greek Φιλαδέλφεια, brotherly love), borrowing a place-name of sectarian significance in Lydia, Asia Minor, seat of one of the seven early churches.

Philadelphia was the Proprietary capital of the Province until 1776; capital of the State until 1799; capital of the United Colonies until 1781; capital of the United States under the Articles of Confederation from 1781 to 1789 and under the Constitution from 1790 to 1800.

Independence Hall, Philadelphia's most celebrated structure, which is a few squares east by south of the city-hall, is in lat. 39° 56′ 57·54″ N.; long. 75° 8′ 57·5″ W. Chestnut street pier is 101·6 m. from the Atlantic. An official tabulation of point-to-point airline distances between the Philadelphia Municipal air port and five well-known places follows: New York, 79 m.; Baltimore, 81 m.; Washington, D.C., 119 m.; Pittsburgh, 260 m.; Boston, 283 miles.

Geography.—Between the Delaware river and the nearest mountains, the Kittatinny range, is the 60 m. wide Philadelphia Piedmont plateau, invitingly fertile, and, in early days, heavily timbered with oak, hickory, chestnut, tulip-poplar, beech, dogwood and laurel. As the city has had much to do with the development of its "back country" so, conversely, the Philadelphia Piedmont plateau, with its many cities, towns and rich townships has contributed greatly to the growth of Philadelphia. And as the Delaware comes down from the north-east, or Minisink country, so the lesser Schuylkill, with its numerous tributaries, comes down from the north-west, out of the anthracite coal-fields, bisecting the Piedmont diagonally, breaking over the last score or more of falls at tidewater and joining the greater stream at the obviously strategic point of the whole region—the Coaquannock of the Indians; the Ft. Beversrede of the fur-trading Dutch; the Tacony-Tinicum of the Swedes and the Philadelphia of to-day.



BY COURTESY OF UNDERWOOD AND UNDERWOOD
INDEPENDENCE HALL, PHILADELPHIA

Topography.—All of old Philadelphia, with the main part of the new, lies on the peninsula of dry land between the Delaware and Schuylkill—a Dutch word meaning hidden river, or, more literally, skulking creek; the Indian name was Manayunk. But the city spreads south-westward beyond the Schuylkill, over the dike-protected Tinicum lowland (in places 5 ft. below high tide) to Darby and Muckinpalus creeks and extends westward across rising ground from 100 to 200 ft. high, as far as Karakung creek, now Cobb's. Thus the city is both longer (24½ m. from the extreme south-west on Bow creek to the extreme north-east point of Poquessing creek and Frankford avenue) and broader (15 m. from Northwestern avenue, and the Schuylkill, Roxborough, to Poquessing creek and Delaware river, Torresdale), than the peninsula, which has three levels—the lowland (Passyunk) section of mud, blue clay and gravels; the elevated section from Spring Garden street to the northern boundary; and the elevated west Philadelphia section to the western boundary.

Sewerage.—Sewerage profits by the natural drainage of small valleys and their watersheds, which involve the utilization of many creeks. It comprises (1928) 1,647·66 m. of sewers, of which 479·73 m. are main sewers and 1,167·93 are branches. Their diameter ranges from 1 to 24 ft. So great is the volume of water in some of these creek-sewers (for instance, the Cohocksink and Mill creek) that costly blow-outs have occurred. A new oval-shaped sewer in the bed of Mill creek, big side down, permits a freer flow. Subway building has caused much sewer reconstruction and metropolitan development in the old city has necessitated great changes. Since 1910, two extensive sewerage disposal plants have been built. In the lowlands, sewers are clogged by mud brought in by flood tides. The part of the Schuylkill delta below its lowermost reach is cut into by tidal estuaries, forming numerous islands. In this section (40th ward), the sewage problem presents difficulties. But in 1925 work was begun on the Mingo pumping system, by which the sewerage, drained into a central basin, is pumped at the rate of 1,000,000 gal. daily into the 40th ward disposal plant. Prior to the establishment of the Mingo system there were great numbers of unsewered houses in the 40th ward. Throughout the city these now (1928) total 10,000, as against 60,939 on Jan. 1, 1911.

Water-supply.—Philadelphia built the first municipal waterworks in America. Councils authorized a "Wholesome Water" loan ($203,001.70); and ground for reservoirs was broken on the site of the old British fort at Fairmount, March 12, 1799. The first water was sent through the pipes—then of wood, a little later of cast-iron—on Jan. 27, 1801. Up to 1902, the city's expenditure for water from the Delaware and Schuylkill had been $56,498,000. Then it became necessary, on account of river pollution to provide for the present comprehensive sand filtration system. There are five filter plants: Torresdale, 52 ac., capacity 240,000,000 gal.; Queen Lane, 16 ac., 111,000,000; Belmont, 14 ac., 50,000,000 (under reconstruction, 75,000,000); Upper Roxborough, 5·6 ac., 20,000,000; Lower Roxborough, 2·7 ac., 8,000,000; East Park distribution reservoir, three basins, capacity, 688,618,000 gal.; Oak Lane reservoir, 2 basins, 70,000,000; Belmont, 40,000,000; five clear-water basins, 127,000,000; four raw-water reservoirs, 609,-350,000. At the 12 pumping stations are 46 electric or steam-driven pumps, with a total capacity of 2,310,000,000 gal. in 24 hours. Much artesian well water is used in the city and out.

City Plan.—Philadelphia was built on a plan. Penn wanted an open-spaced, well-shaded town, with every dwelling in the centre of its plot. There was eventually a complete departure from this idea. Brick buildings, standing wall to wall and so much alike that a man hardly knew his own house, filled large sections of the 19th century city. Another of Penn's ideas was to have "a promenade on the high bank of the river-front the whole length of the city—a top-common from end to end," after the manner of the celebrated Bomb Quai at Rotterdam. But this detail of the original plan was likewise unexecuted. Penn wanted a 10,000 ac. city; Thomas Holme, his surveyor-general, succeeding Penn's cousin, Capt. William Crispen, used less than a third of that space in the original urban section, making up their due allotment to the first purchasers, or adventurers, by assigning them much larger additional lots in the adjoining Northern Liberties. Penn expected the Delaware and Schuylkill halves of his city to meet at Centre square; but necessity, or convenience, caused the development to be along the Delaware, up and down, rather than in the wooded westward parts of the area plotted by Holme. This area—the nucleus and heart of the present city—was a parallelogram in shape, a mile north and south, and two miles east and west from river to river, with a Delaware front street and a Schuylkill front street. The Broad street of to-day, which extends for 11·7 m. from League island to township line and York road, is 113 ft. wide. At Centre square, Market street, 100 ft. wide, crosses Broad, halving the city, north and south.

The most conspicuous object in Philadelphia is the architecturally much criticized City hall, French Renaissance style, designed by John M. Arthur, Jr., with its tower, 547 ft. 11 in. high, topped by Alexander Calder's colossal bronze statue of William Penn. With its courtyard, it occupies an area of 4½ ac. The public buildings commission—authorized Aug. 5, 1870, abolished July 1, 1901—erected it at a cost of $25,000,000 (not without public scandal). The foundation stone was laid on Aug. 18, 1872. Here are housed the State and county courts and municipal and county offices. Across the plaza to the north-east is the new City Hall annex, an office building harmonizing with the adjacent Wanamaker and Widener buildings. Old ferry and township roads in Southwark, Passyunk and Moyamensing have been modernized into diagonal avenues, running south-west and north-east. In 1928 the urban area was 129·714 square miles.

Streets and Bridges.—Philadelphia has 2,000 streets Houses are numbered decimally, 100 numbers being allotted to each square. Asphalt paving is used chiefly; with vitrified, granite or wood block; total urban mileage, 1,368.

Floating bridges were erected in the 18th century over the Schuylkill; in the 19th century permanent bridges. White and Hazard's foot bridge was the first wire bridge in the world. Until recently, Girard avenue bridge was the widest. Ellet's suspension bridge was the first American bridge of the kind. Chestnut street bridge is the largest cast-iron arch-bridge. Below Walnut street the bridges are "swings" and bascules. Spring Garden bridge, like that of Girard avenue, is of wrought-iron, Whipple-truss type. Green Lane (under construction), is of re-enforced concrete. A fine concrete arch-bridge spans the Wissahickon at Walnut Lane. The Philadelphia-Camden bridge is (1928) the longest suspension bridge in the world; construction began Jan. 6, 1922; it was opened July 1, 1926; cost, $37,196,971. Total length, 1·81 m.; main span, 1,750 ft. between towers; height of towers, 385 ft. mean high water; overall width, 125 ft. 6 in.

Parks.—There are 140 parks and playgrounds, covering 7,000 ac. Playgrounds and recreation centres are supervised by the bureau of recreation, and small parks and squares by the bureau of city property. The Fairmount park commission (15 members, appointed by the common pleas judges) has charge of Fairmount park, 3,597 ac. and 22 other parks, with an acreage of 1,407, of which the largest, Pennypack park, has 1,097 ac.; Cobb's Creek, 621; League Island, 275; Roosevelt Boulevard, 250; Hunting park, 86; Wister's Woods, 44; and Bartram's garden, 37. Fairmount park (with the parkway) is practically continuous from City Hall to the county line on the Wissahickon. It originated in June 1812, with the acquisition of a 5 ac. tract (summer-home of Robert Morris, financier of the Revolution) and was repeatedly enlarged by other purchases, until in addition to Letitia Cottage, it now contains 15 historic mansion houses, two surviving structures of the Centennial Exposition (Memorial hall and the Horticulture building) and hundreds of miles of driveways, avenues, footpaths and bridle paths, beautified at many points of vantage with over 50 bronze groups and figures.

Periods and Landmarks.—There have been four phases in the development of Philadelphia: (1) The well-built, though ill-paved, Colonial trading-town of English Quakers and Episcopalians, Welsh Quakers and Baptists, Germans of various sects, Scotch-Irish Presbyterians and inter-colonial migrants. (2) The rapidly growing city of Franklin and Girard, with its shipyards, ropewalks, fleets and fast-sailing ships, its rich merchants, its skill in handicraft and its undemocratized social order. (3) The 19th century brick-paved, red-brick city that was revolutionized by the application of steam-power to many industries—a period of mill, rail and mine development and of a heavy inpouring of Irish and German immigrants, with skilled workers from British industrial districts. (4) The city that has been transformed during the last quarter of a century by such modern agencies as electricity, steel and concrete, and the extensive use of capital.

The earliest city was centred about High street hill (Second and Market); with its long-vanished "Great Towne House," built in 1707 in the middle of the street. Annexed were the covered markets. Nearby was the Friends' meeting house. The slate-roof house and many two- and three-storey brick dwellings with dormer windows were close at hand. Some of these dwellings still stand. Much like the early proprietary town was the revolutionary city, which had grown five squares westward to the Statehouse.

This building, designed by the famous lawyer Andrew Hamilton and built between 1732 and 1741 became Independence Hall, where the Liberty bell once rang, and is now housed. The bell was made by Thomas Lister of Whitechapel, London, but was twice recast because of brittleness, and was hung in April, 1753. It was cracked, July 8, 1835, while tolling a knell for Chief Justice John Marshall, of the U.S. Supreme Court. This court first sat in an adjoining building (built in 1791) of the same group, later the mayor's office, at the south-west corner of Fifth and Chestnut streets. At the south-east corner of Sixth and Chestnut is the hall (built 1791) where the first U.S. congress sat. City councils, until transferred, used Independence Hall. These buildings (much dwarfed at the present day by massive structures east, south and west, including the Curtis block) have been set apart as public monuments. The Statehouse yard of 1729, or Independence square, belongs to the group; and adjoining is Washington square. Associated with Independence Hall is Carpenters' Hall, owned by the company of Master Carpenters, used as a meeting place by the First Continental Congress (1774–75). This well preserved sample of the brick-layer's art was built in 1770–71.

Other shrines are Franklin's grave (south-east corner Fifth and Arch), the Betsy Ross flag-house (239 Arch), the site of the house in which Jefferson wrote the Declaration of Independence (south-

west corner Seventh and Market), the site of the Philadelphia residence of Gen. Washington (528 Market) and the Chew Mansion, "Cliveden" (Johnson street and Germantown avenue), scene of the critical action at the Battle of Germantown, Oct. 4, 1777.

The 19th century city retained much of its 18th century aspect —uniform houses, with pressed brick fronts, white or green shutters and marble steps and trimmings. These were multiplied, row on row; but not until 1850 was there noteworthy growth west of Broad street. That development came after the Consolidation act. Girard avenue was then Franklin avenue. It was crossed by the northward-growing city, which reached and passed Columbia avenue prior to the International Exposition of 1876 (Centennial). This world's fair greatly aided Philadelphia's industries. The 19th century city continued its expansion along residential lines until the period of latter-day small house demolition and sky-scraper development.

Architecture.—Early dwelling houses and halls reflected English ideas. Something of Sir Christopher Wren's manner is traceable in such structures as Christ church (1727–47), Dr John Kearsley, amateur architect, and St Peter's (1761); and Inigo Jones's influence is seen (from prints found in Sir Wm. Chambers's *Treatise on Civil Architecture*) in the street fronts of brick. Many Georgian houses of the 18th century are preserved, Independence Hall being typical. Philadelphia architects in the 20th century have sought to recapture the spirit of colonial times; but the best Georgian restorations and reproductions are not as often seen in the city itself as in the suburban places closely associated with early American history. Grecian influence was shown just before the opening of the 19th century in the works of William Strickland, Thomas Ustic Walter and their followers. Much of Strickland's work has disappeared, save in prints, but the old U S. Mint, at Chestnut and Juniper, was an example of it; and the Custom house (1824) is a surviving specimen. Pseudo-classic structures—the Bank of the United States, Third street (1795); the first Chestnut street theatre; the church of St Luke and Epiphany; St. Andrew's P E church; St. Patrick's church; and, especially Girard college and Ridgway library—belong to this period.

Latter-day buildings of like impressiveness—the U S. mint, the art museum, the free library—would seem to be improvements upon the models of the time of Strickland and Walter. Following these designers there was an architectural "dark age" in Philadelphia until the Centennial Exposition caused an awakening The T-Square club (1883), the school of architecture at the university of Pennsylvania and the Philadelphia Chapter, American institute of Architects, have accomplished much in community, city and regional planning and in influencing architectural designs

Art, Science and Letters.—Long after its loss of precedence in population, Philadelphia preserved its leadership in art, letters and science. Art development began in the period of Benjamin West, the Peales (Charles Willson, Raphael and Rembrandt), Stuart, Sully and Allston, and continued through the 19th century, with J. W. Jarvis, Henry Inman, C. R. Leslie, Paul Weber, H. J. Thouron, J. R. Lambdin, S B Waugh, Thomas Eakins, Thomas P. Anschutz, J. M. Hamilton, John Sartain and Charles Grafly The Academy of Fine Arts, oldest art institution in the United States, dates officially from 1805, but it actually originated in 1791, growing out of Charles Willson Peale's activities in starting the Columbianum (1794), which next year held an exhibition in Independence Hall. Philadelphia now has 37 art associations, museums, schools and collections, public and private.

On the leveled top of Fairmount, at the point where the parkway joins the park, and looking up the Schuylkill, stands the new $20,000,000 Pennsylvania Art museum, opened on March 26, 1928. In situation and design, this group suggests the Parthenon and the Acropolis—an impressive Greek imitation, of severity and dignity. This building, in which delicate curves instead of straight lines are used, is of Minnesota stone. The architectural details in the cornice, as well as the 4 ac. of roofs, are of glazed polychrome terra-cotta. Colour is much used. The seven strata in the dolomite quarry from which the stone was secured vary from a pinkish yellow to a yellowish-grey. The museum is the home of important collections of paintings hitherto inadequately housed. It also offers educational facilities, providing a panoramic history of art for its students and visitors in a series of 37 "period" rooms, in which works of art are shown in their appropriate surroundings.

The American Philosophical society, an outgrowth of Franklin's "Junto" (1727) and the American Society for Promoting and Propagating Useful Knowledge (1766), was organized in 1769. It is housed in Independence square (Frankliniana, 14,000 vol.; library, 45,000). Other scientific societies are the Franklin institute (1824), essentially a society for the promotion of applied science; the Academy of Natural Sciences (1812); the Wagner institute (1855), primarily a society for spreading science among the people; the Spring Garden institute (1851), for teaching useful arts to wage-earning youths; the Commercial museum, containing exhibits illustrating world-wide industrial progress; and the Geographical society

Early publishers, 17th and 18th centuries, issued Bibles—in German, as well as English,—newspapers, almanacs and magazines. The Ephrata, Saur and Aitken Bibles, Franklin's *Poor Richard's Almanac,* many Quaker books, the early Bradford publications, early magazines (especially Joseph Dennie's Portfolio 1801–37), Pennsylvania histories by Thomas, Budd, Smith and Proud, and Charles Brockden Brown's novels are notable publications. Tom Moore, the poet, and Edgar Allan Poe lived in the city, which was also for a time the home of Longfellow, Holmes, Whittier and Lowell. Godey's (1850–77), Graham's (1840–59) and Sartain's magazines as well as Robert Walsh's *American Quarterly Review* (1827–37) were successful publications; and Mathew Cary, George Lippard, Robert Montgomery Bird, with the Hopkinsons—Francis and Joseph—and the Neals—Alice and Joseph C—won notable names. Later, Walt Whitman, Bayard Taylor, George H. Boker, T Buchanan Reed and Charles G. Leland were of literary consequence They were succeeded by S. Weir Mitchell, Frank Stockton, R. H Davis, Horace Howard Furness, F E Schelling, Owen Wister and Agnes Repplier. To-day there are about 200 publishers, including Lippincotts of the third generation.

The leading newspapers of to-day are *The Public Ledger* (Rep., 1836); *The Evening Ledger; The Record* (Ind. Dem., 1870); *The Inquirer* (Rep., 1829) and *The Evening Bulletin* (1847). Outstanding editors: Poulson, Chandler, Forney, McClure and G W Childs (*q v.*).

Theatres and Music.—Philadelphia has 51 theatres (1928) and 167 moving picture houses. One of the London Hallams, Lewis, was the founder of the Philadelphia stage, in 1754. The original Chestnut street theatre (1793) was burned The oldest theatre in the United States, Walnut (capacity 1,512), dates from 1809, and was the scene of the triumphs of Wheatley, Cooke, the Wallacks, Kean, Forrest, the Booths, Clarke, Charlotte Cushman and Rachel. The Arch street theatre (1828) was associated with the Drews and Joseph Jefferson, as well as with W. E. Burton and the Davenports. For a generation, the most noted performers appeared at J. F. Zimmerman's Chestnut street opera house (capacity 1,864), which marked the passing of the old stock company system (1880) and the coming of travelling attractions.

The 17th century German immigrants brought over their music; the Moravians had their organs (called "whistle boxes"). Christ church (Protestant Episcopal), and St. Joseph's (Roman Catholic) helped in the 18th century musical development. The Musical Fund society was organized in 1820; and Musical Fund hall was opened in 1824 All the famous European singers who visited America sang there, and at Concert hall, until the opening of the Academy of Music (capacity, 2,729) in 1857. The Metropolitan opera house seats 3,482.

Philadelphia has a vigorous musical life, with 65 societies—the St. Cecilia, 1824; Anacreontic, 1830; Apollo, 1833; Maennerchor, 1835; Cecilian, 1875; Orpheus, 1877; Mendelssohn, 1876; Philadelphia Music Festival association, 1882; Treble Clef and Eurydice, 1886 The Philadelphia orchestra was organized in 1900, the Presser Foundation dates from 1916. The Curtis Institute of Music gives free instruction.

Clubs.—Of the 2,000 clubs in Philadelphia the oldest is the

Schuylkill Fishing company of the State in Schuylkill, which was organized in 1732. The University, Art and Engineers' are notable clubs. There are many of the literary, journalistic and Bohemian cast—Poor Richard, Franklin Inn, Sketch, Plastic, and Pen and Pencil. The New Century, Civic, City and Colonial Dames are women's clubs. The Philadelphia (1834) is the most exclusive club; the Union League (1862), the most famous.

Churches, Charities and Hospitals.—Philadelphia has 1,032 churches, of which 102 are Baptist; 123 (synagogues and congregations), Hebrew; 37, Lutheran; 120, Methodist Episcopal; 117, Presbyterian; 123, Protestant Episcopal; 140, Roman Catholic; 7 Hicksite Meetings and 5 Orthodox meetings. Society of Friends, Dunkers, Mennonites, Moravians, Schwenkfelders and other sects of Penn's time, still thrive. Philadelphia is the cathedral city of the arch-diocese of Philadelphia, which has 374 parishes and 979 priests of all orders. Five denominations have Divinity schools.

There are 2,500 religious and humanitarian societies in Philadelphia. There is a record of the charitable work of secular societies from the year 1749, and of church societies from 1761 to 1928. The Federation of Charities began in June, 1921. The Welfare Federation embraces 128 non-sectarian philanthropic agencies in the city and suburbs—homes and hospitals for children, dispensaries, emergency aids, day nurseries, settlements, sanitariums, shelters, etc. In 1928 the sum of $3,289,673.60 was subscribed for the Federation. The Jewish Federation raises a similarly large sum. The 27 Catholic charitable institutions are less closely federated.

Philadelphia has been a medical-surgical centre from early days. Its first hospital, the Pennsylvania, which occupies a square in the old city, was chartered on May 11, 1751. The first school of anatomy was established in 1762; and the first medical college (*see* PENNSYLVANIA, UNIVERSITY OF, which now has several affiliated hospitals) in 1765. The first medical society was organized in 1768 and the first College of Physicians in 1787. Its Mütter pathological collection is especially notable. Its library contains 100,000 volumes. Other early institutions are Will's Eye hospital (1832); Pennsylvania hospital of the Insane (Kirkbride's, 1836); Homeopathic Medical college (Hahnemann's, 1848); and the Woman's Medical college (1850). Blockley, long in disrepute, has been erased from the map, and a modern City hospital erected in its place, at a cost of $4,000,000. Among the larger hospitals are Lankenau, Methodist Episcopal, Misericordia, Jefferson and Presbyterian. There are 90 hospitals in the city.

Education.—Enoch Flower was the first school-master (1683) in Philadelphia. In 1689, George Keith started the Friends' Public grammar school, called "Friends' Free," being like the English (but unlike the latter-day American) "public school"; it was chartered in 1701, and became the existing William Penn Charter school. Church and community schools followed. Christopher Dock, who came from Germany in 1714 and who published the first American book on teaching, was the most noted early 18th century teacher. Though the Pennsylvania Constitutions of 1776 and 1790 declared for "free schools," they were charity (called "Ragged") schools; and not until 1818 did the present public school system emerge.

Meantime, numerous academies were established such as Germantown (1760) and Episcopal academy (1785). Other institutions developed: College of Pharmacy (1821); Jefferson Medical college (1825); Woman's Medical college (1850); Protestant Episcopal Divinity school (1862); Lutheran Theological seminary (1864); La Salle college (Roman Catholic, 1867); St. Vincent's Roman Catholic Theological seminary (1868); Medico-Chirurgical college (1881), now affiliated with the university of Pennsylvania and Hahnemann Medical college (1888); the Williamson Free school of Mechanical Trades (1888); Drexel institute (1891); and Temple university with a large student-body and many schools, at Broad and Berks. Gratz college (1893) and Dropsie college (1907), were founded in furtherance of Hebrew learning. The university of Pennsylvania (*q.v.*) is the largest educational institution in the city. (*See* ART and SCIENCE for other educational institutions. For Girard college, *see* GIRARD, STEPHEN.)

Public Schools.—In 1818 the old board of control gave way to the board of education, and the Lancasterian plan to the common schools. The first Central high dates from 1838; Girl's high, 1859 and Girl's high and normal, 1876. At the end of the 19th century, it was manifest that the blight of politics was on the public school but reforms were successfully inaugurated. Two high schools have been succeeded by 13, with 18 junior high schools. There are evening high schools, evening elementary schools, classes in English and citizenship, classes for handicapped children, vocational schools and summer schools. In 1927 the total enrolment was 301,490 and the disbursements amounted to about $40,000,000. There are 241 public schools, in 363 school buildings; of these, 207 are elementary.

Libraries.—Several growths of increasing vigour sprang from the seed sown by Franklin in the "Junto" period of the 18th century—the American Philosophical society, already noted, the university of Pennsylvania and the Library company of Philadelphia, organized on July 1, 1731. Franklin was its London agent, 1760–75. It absorbed the association and union libraries and, in 1792, became trustee for the library of James Logan, which, through the benefaction of Dr. James Rush, was nobly housed (1868) in a granite structure of the classic order. The Library company, with its noted collections—Philadelphia material, Civil War books and Americana—has 275,000 volumes. Other libraries (in addition to those noted under *Science* and *Art*) are those of the Pennsylvania hospital, 1761; the College of Physicians, 1789; the Athenaeum, 1813; the German society, 1817 and the Apprentices', 1820. The Free library of Philadelphia, chartered in Feb. 1891, has a main building, 29 branches and four deposit stations in various parts of the city; 23 of the branch libraries occupy structures erected from Andrew Carnegie's gift to the city of $1,500,000. The Free library had in 1928 706,160 vol., 73,858 pamphlets and 480,786 unbound documents. The art and music departments are especially rich. There is also a library for the blind. The Law library in the City Hall dates from 1802. The Biddle Law library is at the university of Pennsylvania, which, besides the general library (1749)—noted for its Danteana, American and Spanish drama and incunabula—has 13 special sub-libraries. The Mercantile library (224,762 vol.), is notably strong in Irish literature, Shakespeare and Junius letters. The Special Libraries council of Philadelphia lists 155 libraries in the city and environs, with 15 private collections, accessible to students upon application. Historical and genealogical students from all parts gather at the library of the Historical Society of Pennsylvania.

Port.—Transatlantic, coastwise and West Indian trade developed early. Grain, flour and lumber were exported. In 1725, 140 vessels arrived and cleared; in 1735, 427. During the Revolution, Philadelphia became an interstate port, profiting by the imposition of import taxes on goods brought in for trans-shipment. Marine construction grew apace; and Philadelphia ships and sailors won high repute. The Humphrey model revolutionized frigate building. The old navy yard gave place (1876) to the League island yard. In the Girard epoch (1775–1831) came fast clippers; and, after the Fisk-Fulton-Rumsey-Evans period of steamboat experimentation, came the Liverpool packet service of Thomas P. Cope. Then Peter Wright and Son handled Liverpool boats. The Cope, Winsor, Clyde, Ericsson lines identified themselves with the river. The Corn Exchange (1854) became the Commercial Exchange (1868). Pilot service was established on Oct. 4, 1788. The station for pilot boats is at Overfalls light, 89 m. from Chestnut street pier. The Philadelphia-to-the-sea 35 ft. channel was near completion in 1928. The Schuylkill channel is 30 ft. deep. Delaware avenue, the riverfront street, originally 25 ft. wide, has a present width of from 150 to 250 ft., and a length of 20 miles. In the middle of this marginal street are four railroad tracks, including the Belt line, which affords direct track connection for three trunk roads, by means of sidings, with all piers. There are 15 piers belonging to the city and 26 under corporate or private ownership, besides the U.S. Government piers. The main triple-decked tide-water terminal is 1,500 ft. long, can simultaneously berth 15 steamships,

and has 1,000,000 sq.ft. storage space. At Port Richmond, the Philadelphia Electric company occupies 3,000 ft. of river frontage with one of the largest steam-electric plants in the world. The Reading company's Port Richmond terminal has a river frontage of 1 m., a trackage of 60 m. and storage for 6,000 cars. It is said to be the largest tide-water terminal in the world. It has a perishable produce terminal, a large grain elevator and also electrically operated ore-loading machinery with a capacity of 1,200 tons per hour. The Pennsylvania railroad has elevators at Girard point. The Greenwich point coal plant handles 500 cars a day. The water front extends 37·21 m., of which 16·89 m. are in use; 100 deep-draught steamships can be docked at once.

Industries.—Industrially, early Philadelphia led all other colonial towns. Diversification was the keynote then, as it is now. Weavers, knitters, wheel-wrights, glass-blowers and other craftsmen came with the early German immigration. Germantown set the industrial example. The Quakers, Welsh as well as English, fed the city, and handled much of the money. They were successful merchants, shipowners and ship-builders. They manufactured paper, cordage and canvas. Streams were readily dammed near Philadelphia, and there were mills on 16 main creeks. Before the Revolution the Wissahickon had 11 mills. Power for mills was drawn in 1829 by the building of Flat Rock dam on the Schuylkill; and Manayunk came into being. Iron was made at Germantown in 1717. The first Philadelphia carpets were made in 1775. Subsequently English weavers came in great numbers. An industrial north-west section, as well as a great north-east section, was developed. Philadelphia, near water but unswept by strong breezes, has a moist climate peculiarly suitable for textile manipulation.

Manufactures.—Philadelphia's pre-war (1917) products amounted to $784,500,000; in 1925, they had grown to $1,890,990,199. In the whole city, there were, in 1925, 1,040 textile plants, giving employment to 89,113 workers. Metals and metal products employed 67,002; paper and printing, 33,030; food, 23,148; chemicals and allied products, 18,693; leather and rubber goods, 11,422; tobacco, 9,100; lumber, 7,891; clay, glass and stone, 3,519. The Baldwin locomotive works (removed from the heart of the city to Eddystone) has 6,430 employees; Disston's, 2,017; the Budd company, 5,578; Electric Storage, 4,050; the Atlantic Refining company, 6,783, and numerous concerns employ over 1,000.

Transportation.—Philadelphia is the headquarters of the Pennsylvania railroad. The Philadelphia and Reading and Baltimore and Ohio have great terminals in Philadelphia.

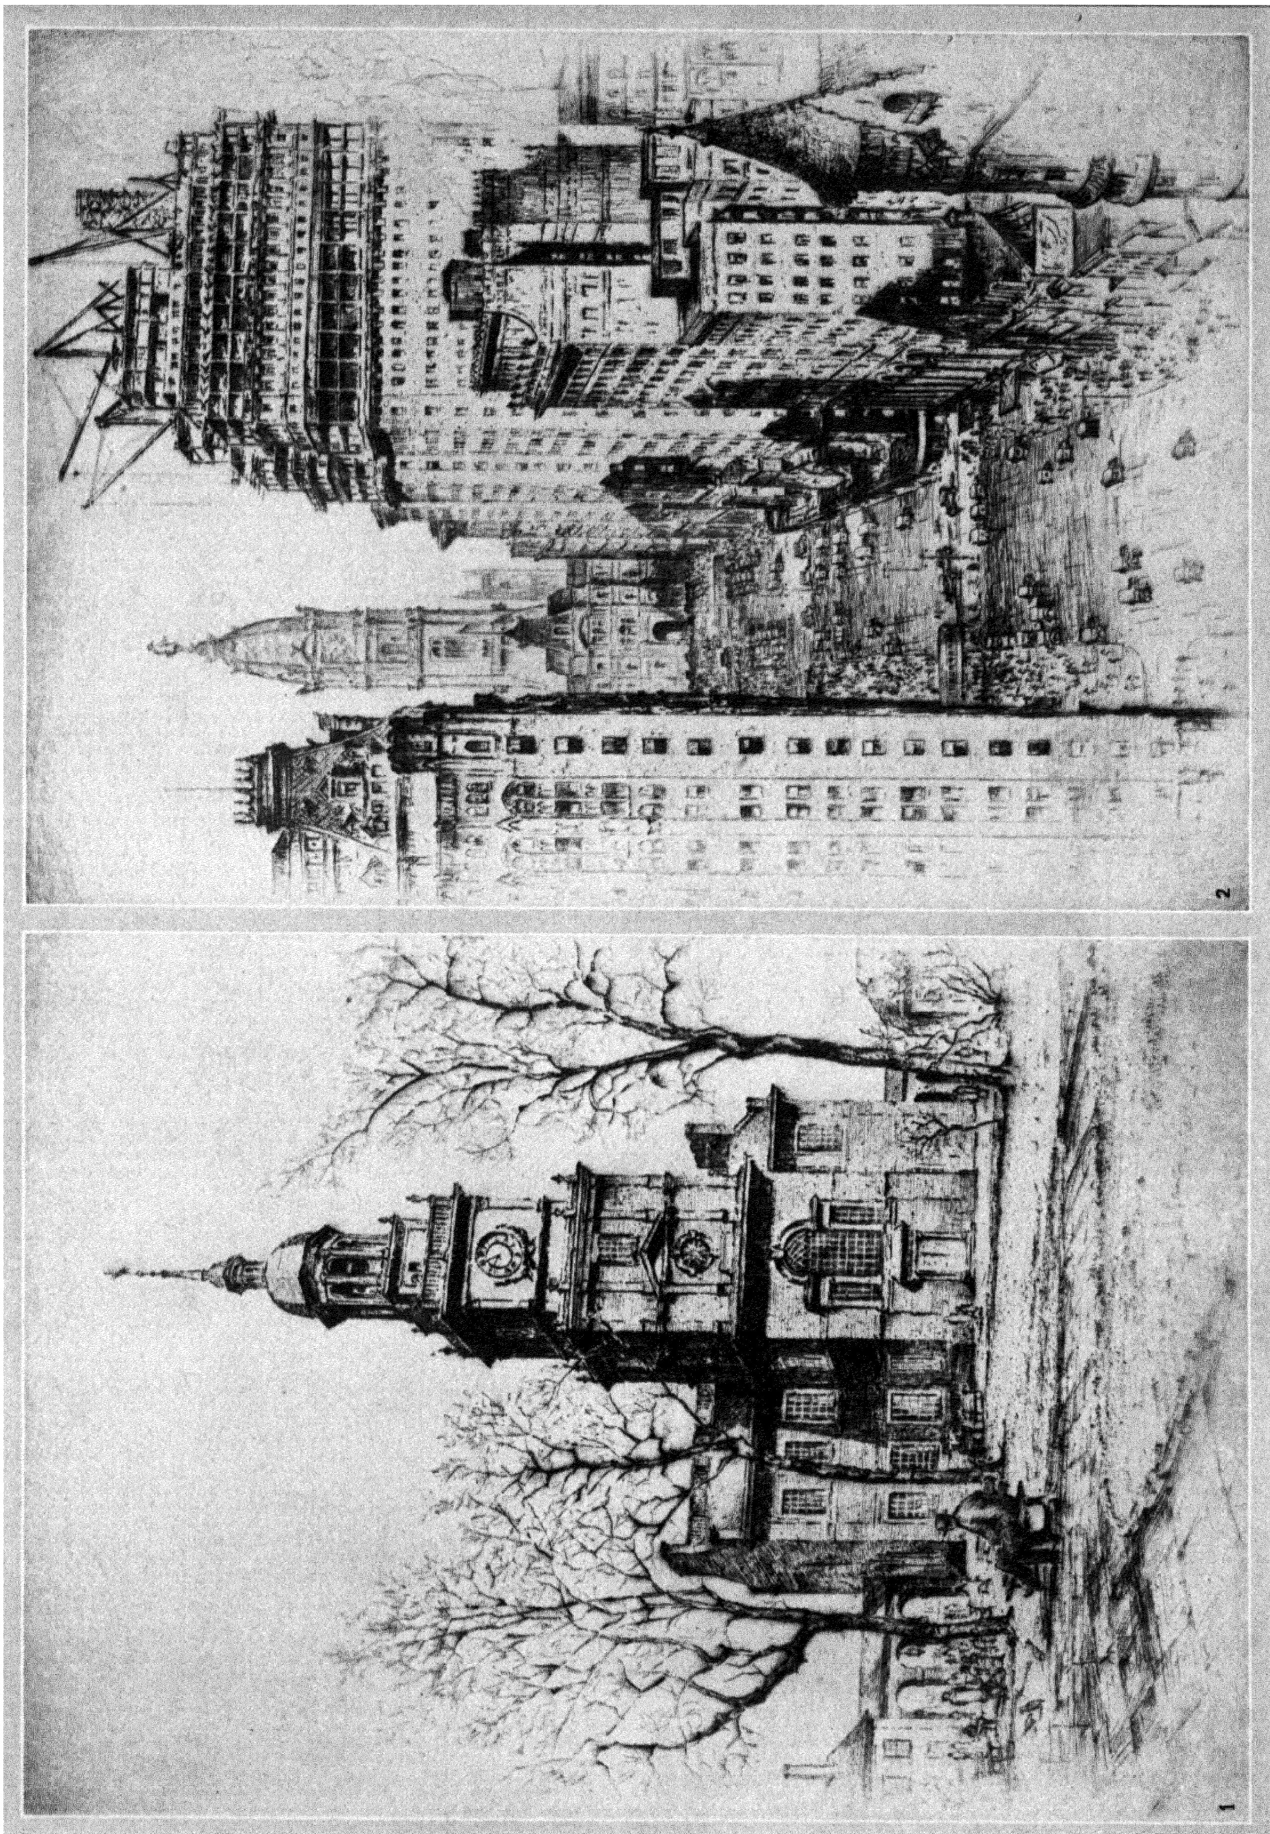
Intra-urban transit is by electric-subway and elevated trains, or by surface trolley cars. All intra-urban roads are operated by the Philadelphia Rapid Transit company under contract with the city since July 1907. The Frankford "L" was built and equipped by the city at a cost of $15,603,992 and leased to P.R.T. in 1923. Subways built by the city are similarly leased. The city-built North Broad street subway was completed in 1928, at a cost of $100,000,000. The Philadelphia Rapid Transit operates urban and suburban taxicabs and motor-buses. Fifty companies, with 750 buses operate between the heart of the city and 150 outlying towns.

Finances.—The first bank in the United States (Pennsylvania bank) was organized in 1781. The Bank of North America was chartered by the Continental Congress in 1784. The first building and loan association in the United States was the Oxford Provident and Building association, organized in Frankford (now 35th ward) Jan. 3, 1831. Of the 12,525 building and loan associations in the United States (1927), Philadelphia had 3,428, with 1,875,089 members, and assets of $743,312,024. There were, in 1927, 94 institutions under the commonwealth of Pennsylvania; 28 operating under Federal charter; and numerous private banking houses. Of those that report to the State secretary of banking, the capital stock paid in totalled $81,736,177; surplus and undivided profits, $192,856,327; deposits, $1,245,774,592; liabilities, $1,582,702,408. The Federal Bank reports showed these totals: Capital, $31,275,000; surplus and undivided profits, $87,556,170; due to the banks and bankers, $182,707,356; liabilitie $865,462,877. Philadelphia is the headquarters of a Feder Reserve district.

City Government.—An act of the Assembly, approved ‹ June 25, 1919, regulates the present government of Philadelphi The mayor, chosen for four years, and 70 other officials (includi 30 judges and 28 magistrates, with the receiver of taxes, ci treasurer, city controller, district attorney and sheriff) are electe from the city at large. The 22 councilmen, now paid officia serving for four years, are elected from eight State senatori districts, one for every 40,000 assessed voters. The Council the chief tax-levying body: it fixes the annual budget and po sesses legislative powers including the right to override the mayor veto. Council business is transacted through committees. The are 12 departments of city government, with numerous boar and commissions: public safety, public works, public healt public welfare, wharves, docks and ferries, city transit, city trea urer, city controller, law, civil service commission, departme of receiver of taxes and department of supplies. The first s (known as "cabinet" departments) are the major administrati units, directly under the supervision of the mayor, who appoin the directors. Under the director of public safety are six bureau: (*a*) police, 5,221 officers in 28 districts; (*b*) fire, 69 engine, truck and 19 other companies, including river service, and six i surance patrols; (*c*) electrical bureau; (*d*) elevator inspectio (*e*) boiler inspection and (*f*) building inspection. Under the dire tor of public works, are bureaux that have charge of water su ply and distribution, highways and city property, including supe vision of 10 curb markets and 87 small parks and squares. Und the director of public health are the bureaux of health and ho pitals, with many divisions and dispensaries; and under the dire tor of public welfare are the bureau of recreation, supervising playgrounds and 34 swimming pools and two other bureaux dea ing with charities and legal aid. Certain offices are known county offices—those held by the controller, treasurer, distri attorney, sheriff, coroner, clerk of quarter sessions, prothonotar register of wills and recorder of deeds. In 1928 there we 19,701 city and 2,565 county employees. Many courts sit the city—Federal or State; and six kinds, including the m nicipal court organized for special purposes, have jurisdictio coterminous with the city and county. Five registration co missioners, appointed by the governor, have charge of the regi tration of voters, appointing four district registrars in each the 1,471 election divisions of the city. Two of the five mu belong to the minority party. One of the three elective commi sioners, who administer the election machinery, must belong the minority party. An important aid to city government is t privately supported citizen's agency, the bureau of municipal r search (organized 1908, incorporated 1910), which is managed a board of trustees. The assessed valuation of real estate returned to the city controller by the board of revision of taxe Jan. 27, 1928, totalled $3,325,584,643; and the personal propert $1,128,974,564.28. On Jan. 1, 1925, the gross funded outstan ing debt was $225,967,200, of which the sinking fund he $58,117,900; the interest and sinking fund amounted in 1925 three-eighths of the tax levy.

Light and Power.—The city's first gas works date from Fe 8, 1836. After the consolidation, the combined gas plants we placed under the management of trustees. Political scandals aro and the works were transferred to a bureau of gas; then, lease, to the United Gas Improvement company, which renew the lease, Jan. 1, 1928, for ten years, at a rental of $4,200,0 a year, or 7% on $60,000,000. The Philadelphia Electric co pany, now consolidated with the United Gas Improvement co pany, supplies the electric current for light and power. Work the $52,000,000 hydro-electric plant of the company at Con wingo, Md., was begun in March 1926 and on March 1, 192 the first power from its turbines was sent to Philadelphia ov two 220,000 volt three-phase lines.

Population.—The population of Philadelphia on July 1, 192 was 2,064,200, according to the U.S. Census Bureau estimate First Philadelphia population figures were: (1753) 14,563; (176



Two views of Philadelphia from etchings by Anton Schutz: 1. Independence Hall, built between 1732 and 1741, and used as the Statehouse until 1799. The Declaration of Independence was signed in this building in 1776. 2. Broad Street, the principal thoroughfare north and south, looking toward the City Hall, the business centre of modern Philadelphia

28,043. Philadelphia's official figures, by decades, follow: (1790) 28,522; (1800) 41,220; (1820) 63,802; (1840) 93,665; (1860, after consolidation) 565,529; (1880) 847,170; (1900) 1,293,697; (1910) 1,549,008; (1920) 1,823,779. In 1920, foreign-born whites numbered 397,927; negroes, 134,229. There has been a marked increase since 1920 in the percentage of negroes.

Twentieth Century Development.—Philadelphia's 20th century growth is measured by its demolitions—a paradox readily understood when it is explained that, in the part of the city planned by Penn, during five years (1923–27 inclusive) 3,242 dwellings and 868 other houses were demolished to make room for larger buildings, mainly commercial, and wider streets About 80% of the population live in dwellings, but for several years a change to apartments has been noticeable. This began when the Market street subway-elevated electric railway was constructed.

The Philadelphia of to-day has many times more Federal offices and employees than it had when it was the Federal city. The U S. Government has increased its property holdings tenfold since 1900. Its postal business has grown so fast that, though 1,883 employees then sufficed, 4,832 were required in 1925. The Mint, the arsenals and the supply and equipment stations have increased in efficiency. Site and plant at League island navy yard are valued at $100,000,000, the buildings number 549 The aircraft factory is the largest in the world—46 acres. There are three dry-docks, one of which is 1,064 ft. long and 210 ft. wide. The naval storehouse covers 10½ acres.

Metropolitan (Tri-state) Area.—The central city is a relatively small area but its influence expands in a series of widening circles—10-mile radius, pop. (1927, estimate) 2,322,316; 20-mile, 2,708,184; 40-mile, 3,465,894, 80-mile, 5,349,255 This covers a Tri-State region with 41 towns and cities, 21 in Pennsylvania, 18 in New Jersey and 2 in Delaware Trenton is the largest of the included cities with a pop of 140,283; Camden has 133,814; Wilmington, 119,422; Chester, 64,355; Atlantic City, 50,631; Lancaster, 58,943; Norristown, 35,841; Lebanon, 27,329 and Pottstown, 19,330. The Metropolitan area includes 22% of the area and 49% of the population of the Third Federal Reserve district; produces ⅔ of the manufactures, and has 71% of the wholesale, and 58% of the retail, trade. (G Mn)

PHILADELPHIANS, a sect of religious mystics, founded in London in the latter part of the 17th century. In 1652 Dr. John Pordage (1607–1681), rector of Bradfield, Berkshire, gathered together a few followers of Jakob Boehme, the chief of whom was Jane Lead or Leade (1623–1704) Mrs Leade had been from girlhood of a mystical temperament, and experienced phantasms which she recorded in a diary entitled *A Fountain of Gardens*, beginning in 1670, in which year the Philadelphian society was definitely organized. In 1693 some of Mrs. Leade's writings were translated into Dutch, and by this means and her acquaintance with Francis Lee (1661–1719), an Oxford scholar who studied medicine at Leyden and became her son-in-law, a connection was opened up with Germany and Holland. In 1703 the Philadelphians drew up their confession, but they made no further progress and soon declined, the Dutch branch withdrawing and the English government forbidding the society to meet

PHILAE, an islet in the Nile above the First Cataract, of great beauty and interest, but since the completion of the Aswan dam in 1902 submerged except for a few months yearly, when the water is allowed to run freely through the sluices of the Aswan dam. Philae marks also the end of the cataract region. Ancient graffiti abound in all this district, and on Bigeh, a larger island adjoining Philae, there was a temple as early as the reign of Tethmosis III. About 350 B C. Nekhtnebf, the last of the native kings of Egypt, built a temple to Isis, most of which was destroyed by floods. Ptolemy Philadelphus reconstructed some of this work and began a large temple which Ptolemy Euergetes I. completed, but the decoration, carried on under later Ptolemies and Caesars, was never finished. The little island won great favour as a religious resort, not only for the Egyptians and the Ethiopians and others who frequented the border district and the market of Aswan, but also for Greek and Roman visitors. One temple or chapel after another sprang up upon it dedicated to various gods, including the Nubian Mandulis Ergamenes (Arkamane), king of Ethiopia, shared with the Ptolemies in the building. Besides the temple of Isis with its birth-temple in the first court, there were smaller temples or shrines of Arsenuphis, Mandulis, Imuthes, Hathor, Harendotes (a form of Horus) and Augustus (in the Roman style), besides unnamed ones There were also monumental gateways, and the island was protected by a stone quay all round with the necessary staircases, etc , and a Nilometer. The most beautiful of all the buildings is an unfinished kiosque inscribed by Trajan, well known under the name of "Pharaoh's Bed" The decree of Theodosius (A D 378) which suppressed pagan worship in the empire, was of little effect in the extreme south It was not till the reign of Justinian, A D. 527–565, that the temple of Philae was finally closed, and the idols taken to Constantinople Remains of Christian churches were disclosed by the thorough exploration carried out in 1895–1896 in view of the Barrage scheme, under the direction of Captain Lyons. The accumulations of rubbish on the island were cleared away and the walls and foundations of the stone buildings were all repaired and strengthened before the dam was completed. The annual flooding now appears to be actually beneficial to the stonework, by removing the disintegrating salts and incrustations The tops of most of the buildings and the whole nucleus of the temple of Isis to the floor remained all the year round above the water level until the dam was raised another 26 ft —a work begun in 1907 —when the temples were entirely submerged except during July–October But the beauty of the island and its ruins and palm trees, the joy of travellers and artists, is almost gone.

PHILANTHROPY. Almsgiving is as old as man. In the Egyptian *Book of the Dead*, as ancient as the Nile pyramids, there is found this memorial ascription "He gave bread to the hungry, water to the thirsty, raiment to the naked; he gave a boat to the man who had none" Similarly in the ancient Hebrew scriptures we read (Deuteronomy xv. 7 and 8): "If there be with thee a poor man, one of thy brethren, within any of thy gates in thy land which Jehovah thy God giveth thee, thou shalt not harden thy heart, nor shut thy hand from thy poor brother; but thou shalt surely open thy hand unto him, and shalt surely lend him sufficient for his need" And of all the parables to be found in the New Testament none is better known or more deeply burnt into the conscience of Western civilization than that of the Good Samaritan The Muslim world in like manner preserves the maxim· "Prayer carries us half way to God, fasting brings us to the door of his palace, and alms gains us admission" While the spirit of benevolence that animates all philanthropy is unmistakably reflected from the remote past, it is evident that there has been an evolution in the technique of giving. Various groups of the modern social order resent the idea of alms, regarding such forms of assistance as undemocratic. So the use of the word charity is often avoided. Present day benevolence, philanthropy, no longer content with the cure of human ills after they arise, strives ever to prevent them, and, as a final goal, seeks through constructive effort the positive achievement of health and happiness throughout the world. It is a curious fact that the word philanthropy, which in origin means simply "love to mankind," has

no exact equivalent or synonym in our language. Further, its employment as an English word is comparatively recent, one of its earliest appearances in its present form occurring about 1650 in a sermon by Jeremy Taylor. Moreover, the use of the word to designate some humanitarian activity as "a philanthropy" is a development of the last 50 years.

The purpose of this article is not to discuss the history of ancient and mediaeval benevolence, various aspects of which are treated in the article CHARITY, but to indicate the chief developments that have characterized modern philanthropy since about the beginning of the 19th century.

The Nineteenth Century.—Between 1775 and 1800 there were significant beginnings of that notable philanthropic activity which was to characterize the 19th century. Conspicuous among its forerunners in England were John Howard, pioneer in prison reform, and Sir Samuel Romilly, who sought to abolish the barbaric features of British criminal law. In France Charles Michel Epée laid the foundations of modern instruction for the deaf and dumb, and Jean F. Oberlin laboured effectively for social improvement. Another leader was the American scientist, Benjamin Thompson, afterwards Count Rumford, who organized in Bavaria (1785–95) a system of workshops, called houses of industry, thereby largely suppressing begging.

The change from the domestic to the factory system of manufacture at the beginning of the 19th century brought about a great shift of the labouring population, accompanied by a phenomenal growth of cities, nowhere more striking than in Great Britain between 1800 and 1850 and in the United States between 1850 and 1900. In 1800 London was the only city in Great Britain with a population of over 100,000. The next largest cities were Manchester, Birmingham and Glasgow, each of which had about 75,000 inhabitants. Yet at the end of the century all these places, including London, had multiplied in size from more than seven to nearly ten times. In 1800 Philadelphia, then the largest city in the United States, had a population of 28,000, as contrasted with about 150 American cities of equal or greater population in 1900. Similar urban growth took place in Germany, Belgium and other industrial countries of Europe.

This rapid and unparalleled transfer of people from rural to urban conditions gave rise to problems in social adjustment of immense range and complexity. Accompanied by the progress of democracy, the advance of popular education, the increasing sense of civic responsibility, the application of scientific methods and, above all, the ever-widening permeation of the humanitarian spirit, these social transformations formed the background for the development of the great outstanding philanthropies of our time. Most notable among the results of the philanthropic spirit were the great advance in industrial welfare, the abolition of human slavery, improved housing in cities, enlightened care for the defective classes, immense extension of free public education, the organization of the Red Cross society, the charity organization movement, the social settlement movement, the child welfare movement and the establishment of scientifically equipped hospitals.

Among the most notable philanthropists (on each of whom will be found a biographical article under his name) were: Robert Owen, famous for his model mills at New Lanark and later for his communities in England and America; Jeremy Bentham and the Quaker educator, William Allen (1770–1843). Other leading figures were William Wilberforce whose life-effort was finally crowned in 1833 by the passage of an act abolishing slavery in the British dominions, and Elizabeth Fry, in England, who carried on the cause of prison reform initiated by John Howard.

In the United States Dr. Samuel Gridley Howe advanced the education of the blind, and Thomas Gallaudet, with his sons Thomas and Edward Gallaudet, performed equally conspicuous service in the training of the deaf and dumb. In 1833 Anton Frederic Oxinam, a zealous Roman Catholic student at the Sorbonne, with the aid of Père Sylvain Bailly, organized in Paris the Society of St. Vincent de Paul. Within the century this society expanded into a world-wide agency of Catholic beneficence, whose principles and practices of poor relief influenced the charitable practice of our time, in Protestant as well as in Catholic countries. In the same year (1833) Theodor Fliedner, a pastor in Rhenish Prussia, established the Protestant order of Deaconesses, at whose first school in Kaiserswerth Florence Nightingale was trained as a nurse. Shortly before (1827) Miss Catherine McAuley established in Dublin the Sisters of Mercy, whose hospitals and schools have become widespread in English-speaking and other countries.

Lord Shaftesbury's long life is the continuous story of factory acts, child labour acts, mining reform, lunatic asylum reform, public health improvement and housing reform. In 1856 Baroness Burdett-Coutts, who devoted a long life and a large fortune to many-sided philanthropy, began building model lodging-houses at Bethnal Green. In 1862 George Peabody, an American banker living in London, gave a fund of £150,000, later enlarged to £500,000, for the construction of dwelling houses for London working men. In 1864 Octavia Hill began her remarkable housing work at Marylebone with funds advanced by John Ruskin.

The English nurse, Florence Nightingale, by heroic service with the British army in the Crimean War (1854–56), revolutionized the care of sick and wounded soldiers in military hospitals. Further reflecting the humane spirit of the age, the Swiss philanthropist, Henri Dunant, provided aid for wounded soldiers on the battlefield by organizing, in 1864, the Red Cross Society. Under the leadership of Clara Barton the American Red Cross Society was established in 1881 and its function later extended (1906) to provide relief in natural calamities. Henry Bergh, of New York, founded, in 1874, the Society for the Prevention of Cruelty to Children. In 1853 Charles Loring Brace founded the Children's Aid Society of New York city, a pioneer organization in the child welfare movement. In 1867 Dr. Thomas John Barnardo opened in Stepney Causeway, London, the first of the so-called "Barnardo homes" for destitute children.

In 1869 a group of prominent men in England, including the earl of Shaftesbury, J. H. Newman and Wm. E. Gladstone, formed in London the first Charity Organization Society in the world. With a group of Oxford men, Canon S. A. Barnett in 1885 founded in Whitechapel, London, the first university settlement, Toynbee Hall. Dr. Stanton Coit in 1886 established in New York the Neighborhood Guild which later became the University settlement. In 1889 Jane Addams began her work at Hull House, Chicago, and in 1893 two nurses, Lillian D. Wald and Mary M. Brewster, established in New York city the now widely known Henry Street settlement.

In the 19th century, also, the political and economic emancipation of the Jewish peoples of western Europe led to a complete reorganization of Jewish benevolence, accompanied by many outstanding achievements in modern philanthropic endeavour. Among these were the notable activities of Sir Moses Montefiore, of England, in ameliorating the lot of unfortunate co-religionists in lands where they were still oppressed, and also the munificent benefactions of Baron Maurice de Hirsch. The latter established the Jewish Colonization Society, which he endowed with some £11,000,000, making it one of the greatest modern philanthropic trusts; in addition, he contributed extensively to hospitals and other charities in London and elsewhere, the total of his benefactions amounting to about £18,000,000.

In the latter half of the century began the philanthropic efforts to advance higher education in the United States, the individual donations eventually exceeding in size those made for any other single beneficent purpose. These benefactions included an immense number of substantial sums to countless institutions, but most conspicuous were endowments of princely magnitude for the more important colleges and universities. Notable among the early benefactors of American education were Peter Cooper, Ezra Cornell, Matthew Vassar and Johns Hopkins. Later Leland Stanford and John D. Rockefeller made munificent gifts for the establishment of universities and the spread of higher education.

Following the Civil War and the emancipation of the slaves, the education of the American negroes in the Southern States became and still remains an especially worthy object of philanthropic endeavour. Prominent among early contributors of funds or of important personal service to the cause of negro education

were George Peabody, donor of the Peabody Fund; John F. Slater, founder of the Slater fund; General O. O. Howard, commissioner of the Freedmen's bureau; Samuel Chapman Armstrong, founder of Hampton Institute and a leader in negro education; and Booker T. Washington, a conspicuously successful negro educator, who founded Tuskegee Institute.

Another notable expression of educational philanthropy during the latter half of the century was the establishment of free public libraries on an unprecedented scale, especially in the United States. Important among earlier gifts for library foundations were those of John Jacob Astor, James Lenox and Samuel J. Tilden, in New York, and John Crerar, in Chicago. Later came individual gifts for great library buildings, as that of Enoch Pratt to the city of Baltimore and of P. A. B. Widener to Philadelphia, and also gifts for thousands of lesser buildings in smaller cities and towns, for the construction of a large number of which Andrew Carnegie made very numerous donations aggregating more than $60,000,000.

Recent Philanthropy.—At the opening of the 20th century the philanthropic agencies in effective operation immensely exceeded in number, diversity and scope those of any earlier period. Despite the World War there was a substantial advance in every important field of philanthropic endeavour during the first quarter of the new century. In connection with the many phases of this growth two distinctive features developed. One of these was the assumption by the British, French and other European governments of a vast range of social relief which formerly was administered only through private charitable agencies. By parliamentary enactment in Great Britain in 1908 a system of old age pensions was set up. In 1911 came the National Insurance Act, providing against sickness, invalidity and unemployment. Further, in 1928, by the Widows, Orphans and Old Age Pensions Act, a still larger group previously aided through private charity was brought under the scheme of national social insurance.

The second distinctive feature of this period has been the creation of many great philanthropic trusts, especially in the United States. Their underlying constructive purpose is somewhat parallel to that of the British governmental system of social relief. These trusts seek permanent, substantial and far-reaching results through the use of ample funds, efficient organization and modern methods of administration. In the United States alone, where the establishment of such trusts has become a favourite method of the bestowal of large bequests, the total of such funds runs into the thousand millions of dollars. Many philanthropists disapprove of the efforts made by certain benevolent trusts and foundations to perpetuate themselves by restricting their enterprises and expenditures to the interest on invested capital and not only leaving the principal untouched but even adding from time to time to it from unused income. In consequence, various trusts, as the Julius Rosenwald Fund, provide definitely for the expenditure of the entire fund capital as well as income within a specified period.

Among other distinctive gains made in the 20th century have been the effective attacks on disease, as yellow fever, typhoid and tuberculosis; the marked progress in numerous phases of child welfare, and the wide establishment of the juvenile court system in treating youthful delinquents. Important also have been the efforts to promote amicable international relations, as reflected in the Rhodes Scholarships, established (1902) by Cecil J. Rhodes, and (1910) the Carnegie Endowment for International Peace.

The magnitude of philanthropic expenditure in recent years is vastly greater than ever before recorded. In 1926 the British Government distributed, in maintaining its public social service in England and Wales, a total of £313,000,000, of which about £80,000,000 was derived from sums received from contributions from or levies on individuals and companies. In addition to this huge sum—over one-third of the gross income of the British Government—other contributions of large amounts were made to religious, educational and charitable organizations. In Great Britain in 1927 there were recorded 35 private bequests of £40,000 and upwards, the average bequest in this group being £105,000.

In the United States the private donations for philanthropic (including religious) uses estimated at approximately $1,719,000,000 for 1921 rose to $2,330,600,000 for 1928, the average exceeding $2,000,000,000 per year. While the greater number and bulk of all American donations go to religious bodies, charitable organizations and hospitals, as they do likewise in Great Britain, the chief recipients of the largest bequests are universities and colleges. Of 340 major benefactions made in 1928, averaging over $500,000 each, 57% of the total amount went to institutions of higher education. In consequence of the tendency to give generously to higher education, there were in the United States in 1929 about 100 colleges and universities whose endowments were $2,000,000 or more each; the total endowment of this group exceeded $875,000,000.

Further indicative of the trend of recent American contributions to philanthropic purposes, aside from the major objects mentioned above, there were in 1927 donations for the institutional care of children, $94,300,000; for the institutional care of the aged, $64,400,000; for negro education, $30,900,000; for scholarships for needy children, $19,300,000; for public health nursing, $11,800,000; for medical research, $13,000,000; for health education, $6,500,000; for play and recreation, $19,300,000, and for the fine arts, $25,700,000. There were also donations for relief in foreign lands, including Armenia and the Near East, China, Russia, Poland, Austria, Ireland and other countries, amounting to $214,500,000.

The United States.—Philanthropic endeavour in America differs from that of other countries in its greater variety and in the larger proportion undertaken through private initiative as compared with that carried on by the State, while that performed directly under religious auspices is much less. Moreover, as little poverty exists and there is no pauper class, welfare work is conducted in a more confident spirit, with the expectation of making social relief ultimately needless. Again, all forms of public and private relief, including the care of the sick, defective, insane, criminal or indigent, are more and more thought of as parts of a complicated but interrelated system, to be planned for and administered as such. There is also the American readiness to discard old methods, mechanisms and plants and to install new and better devised ones.

The emphasis on prevention has greatly stimulated research into social conditions, and several heavily endowed foundations, as the Russell Sage, the Rockefeller and the Carnegie, include research as a special function. The results of surveys made by research institutions have stimulated the older social service organizations to undertake a greatly widened range of constructive activities and rehabilitations instead of simple relief. Training schools for social workers have been established, and training courses in social work are offered by colleges and universities.

The trend toward prevention is seen also in the changed methods of handling criminals. Reformation, not merely retribution or punishment, has become generally emphasized in the treatment of adult as well as juvenile offenders. Such features as probation, indeterminate sentence, special courts for children and specialized treatment for women and children, which were novelties at the beginning of the 20th century, now characterize the penal and correctional systems of most States.

A noteworthy development is seen in the growing co-ordination of social agencies, the mutual exchange of records and information, and wide-spread co-operation in formulating working plans and programmes. An important outcome of this co-operation has been the founding of financial federations, which have become a basic feature of social welfare work in many American cities. The Jewish charities were the first to inaugurate this plan successfully, but in 1921 some 30 important cities had adopted this method of raising a community chest or community fund, and subsequently the plan became widely prevalent. In 1929 about 350 urban communities were using it.

There has also been a marked tendency toward increased dependence upon government in the field of social welfare. Boards of health have extended their control over infectious diseases, established clinics and maintained nurses and physicians to visit and give instruction to the poor in their homes. Public schools

have added physicians, nurses, dentists and psychiatrists to their regular staffs. In more than three-fourths of the States there is an organized bureau of child welfare, and in most of the States there is some provision for the payment of widows' pensions or mothers' allowances. The Federal Government has granted financial aid for vocational education; the Department of Agriculture has done social work in rural communities, and a children's bureau is maintained by the Department of Labor.

Industrial welfare work, largely a development of the first quarter of the century, beginning in many instances with the installation of a rest room, lunch room and first-aid appliances in mercantile and industrial establishments, has expanded to include gymnasiums, playgrounds, medical counsel and care, summer camps, company stores, mutual benefit societies; in fact, practically everything that may promote the well-being and efficiency of the workers and promote co-operation and good-will between the employers and the employed. (J. Ros.)

PHILANTHROPIC ENDOWMENTS

The accumulation of great fortunes in the United States and the peculiar appropriateness of benevolence in a democracy have been accompanied by an exceptional development of endowed philanthropies.

Benjamin Franklin (1706–90) wrote in his will: "Having myself been . . . assisted to set up my business . . . by kind loan of Money . . . which was the foundation of my Fortune, and of all the utility in life that may be ascribed to me, I wish to be useful even after my Death, if possible, in forming and advancing other young men that may be serviceable to their Country." To that end he left £1,000 to the town of Boston and an equal amount to the city of Philadelphia, to be lent at interest to young, married artificers of good character. Estimating that each of these gifts would have increased to £131,000 after 100 years, Franklin requested the expenditure at that time of £100,000 in public works of useful, convenient and agreeable character, and the accumulation of the remainder for another century, when the whole was to be distributed—one-fourth by the city and three-fourths by the State. In 1891, largely because there had been few borrowers, the Philadelphia accumulation amounted only to $90,000. Of this, $20,000 was left to accumulate for another century; the remainder, accumulated to $133,000 in 1908, was then added to the endowment of the Franklin Institute, which had been founded in 1824, for the promotion of science and the useful arts. Of the Boston accumulation of $391,000 in 1891, $62,000 was left to accumulate for another century; the remainder, accumulated to $408,000 in 1904, was then used to build the Franklin Union, an industrial school, an equal sum being given for its endowment by Andrew Carnegie.

George Peabody (1795–1869), a merchant and banker, of Danvers, now Peabody, Mass., and later of London, established, among many benevolences, an institute, with a library, art museum and conservatory of music, in Baltimore, Md., in 1859; a Museum of Archaeology and Ethnology at Harvard college in 1866; an Academy of Science at Salem, Mass., in 1867; and gave £500,000 for the erection of workmen's dwellings in London in 1864, and $3,000,000 to the Peabody Education Fund in 1867, for "intellectual, moral or industrial education among . . . the Southern and Southwestern states." The fund established and developed public schools until they were taken over by towns and cities; encouraged rural schools and the development of State systems of public education; and promoted the training of teachers by scholarships, and by founding at Nashville, Tenn., in 1875, the Peabody Normal college, which became in 1913 the George Peabody College for Teachers and received the remaining resources of the Peabody Education Fund at its conclusion in 1914.

Andrew Carnegie (1835–1919) carried out his "Gospel of Wealth" by distributing nine-tenths of his fortune in countless gifts—for 8,000 church organs, 3,000 libraries and 500 universities and colleges. Two-thirds of his total distribution of $350,000,000 went toward the establishment and endowment of eight large, permanent foundations. (For full particulars of these foundations see CARNEGIE TRUSTS.)

John D. Rockefeller (1839–) and John D. Rockefeller, Jr. (1874–) have given for philanthropic and charitable purposes more than $550,000,000, together with $45,000,000 to the University of Chicago. The larger portion of this was given for the establishment and endowment of four large foundations. (For full particulars of these foundations see ROCKEFELLER BENEFACTIONS.)

Other large foundations are: (1) the Milbank Memorial Fund, incorporated in 1905, by Elizabeth Milbank Anderson, with $10,000,000, especially for studies and demonstrations of child welfare, mental hygiene and individual and community health; (2) the Russell Sage Foundation, established in 1907 by Mrs. Russell Sage, with $10,000,000, later increased by $5,000,000, for the improvement of social and living conditions in the United States, especially through the organization of charity, education, recreation, remedial loans, social legislation, and through libraries, research, surveys, statistics, exhibits and publications; (3) the Commonwealth Fund, established in 1918 by Mrs. Stephen V. Harkness, with $38,000,000, "for the welfare of mankind," especially through clinics and demonstrations of child health, guidance and mental hygiene; the training of social workers; rural hospitals; and educational fellowships, research and publications; (4) the Juilliard Musical Foundation, of New York, established in 1919 by a bequest of $20,000,000 from Augustus D. Juilliard, for the musical education of gifted students and of the public; (5) the Duke Endowment, established in 1924, by James B. Duke, with $40,000,000, increased by bequest in 1925, for Duke university, other universities and colleges, hospitals, the building and maintenance of churches, pensions for clergymen, and the care of orphans in North and South Carolina; (6) the Julius Rosenwald Fund, established in 1912 and amounting in 1928 to $20,000,000, for the health and education of negroes, other backward races and persons of small means, with the proviso that both the principal and interest be expended within 25 years after the death of the donor. Mr. Rosenwald has in addition made large contributions of time and money to other civic, philanthropical educational enterprises, including Y.M.C.A.'s and Y.W.C.A.'s for negroes. More recent endowments for educational and other philanthropic foundations have been made by Frank Munsey, Payne Whitney, Milton Hershey and Henry E. Huntington.

There are in the United States perhaps 100 endowed philanthropies that are smaller than the large foundations already mentioned but yet larger, more comprehensive, and more independent than the countless separate endowments of specific activities that have been given to religious and charitable organizations, hospitals and other health agencies and to universities, colleges, schools and educational associations. Following the Cleveland Foundation (see COMMUNITY TRUSTS), established in Cleveland, Ohio, in 1914, there have come into existence some fifty community foundations, funds or trusts that are cared for by trust companies and disbursed by committees selected by public officers and representative associations. While no one of these community organizations has as yet been entrusted with permanent resources approaching those of the larger foundations, a number of them have been very useful in conducting surveys and distributing current gifts.

The fears concerning the power of wealth concentrated in foundations and their indefinite continuance of the wishes of their founders, which were formulated by the French economist, Turgot, in 1776, have not been fulfilled. Religious, philanthropic and educational endowments in the United States represent less than 1% of the national wealth; a score of life insurance companies have larger resources than any foundation; a hundred banks have incomes greater than the total new endowments in any year. The "imposition of the dead hand" is prevented and desirable freedom is assured by such provisions as Mr. Carnegie's for spending the income of his endowments for purposes other than those he specified, or Mr. Rockefeller's for spending the principal as well as the income of his gifts, and by legislative

provisions in foundation acts of incorporation or charters that these may be altered or repealed at any time.

Meanwhile the resources of the foundations have given them independence and freedom to concentrate upon particular problems, to carry out comprehensive and continuing studies, experiments and demonstrations. Eminent men have guided them as trustees, and distinguished scholars have collaborated in their studies. Gifts from foundations have greatly encouraged giving to worthy causes; their discriminations have elevated educational standards; their activities have been taken advantage of by many voluntary associations, sundry States and the Federal Government. In fine, the public has come to expect from these privately endowed yet representative foundations much of the aid and guidance that are furnished by government in other countries.

An annotated bibliography of the literature concerning American foundations was issued by the Russell Sage Foundation in 1915, 1920, 1922, 1924 and 1926. (C. Fu)

PHILARET [Theodore Nikitich Romanov] (?1553–1633), patriarch of Moscow, was the second son of the boyar Nikita Romanovich. During the reign of his first cousin Theodore I (1584–98), Theodore Romanov distinguished himself both as a soldier and a diplomatist. On the death of the childless tsar, he was the popular candidate for the vacant throne; but he acquiesced in the election of Boris Godunov, who compelled him, three years later, to take monastic vows under the name of Philaret. Philaret was confined to the Antoniev monastery, but when the pseudo-Demetrius overthrew the Godunovs he released Philaret and made him metropolitan of Rostov (1605) In 1609 Philaret fell into the hands of pseudo-Demetrius II., who named him patriarch of all Russia, though, in fact, his jurisdiction was very limited On June 2, 1619, he was enthroned patriarch of Moscow. Henceforth, till his death, there were two sovereigns, Tsar Michael and his father, co-regents.

Philaret replenished the treasury by a more equable and rational system of assessing and collecting the taxes. His most important domestic measure was the chaining of the peasantry to the soil, a measure directed against the ever increasing migration of the down-trodden serfs to the steppes, where they became free-booters instead of tax-payers The taxation of the tsar's *slyuzhnuie lyudi,* or military tenants, was a first step towards the proportional taxation of the hitherto privileged classes Philaret formed the nucleus of the subsequently famous Patriarchal Library, and commanded that every archbishop should establish a seminary for the clergy, himself setting the example. He also reorganized the Muscovite army with the help of foreign officers. His death in October 1633 put an end to the Russo-Polish War (1632–33), withdrawing the strongest prop from an executive feeble enough even when supported by all the weight of his authority.

See R. N. Bain, *The First Romanovs* (London, 1905); S. M. Solovev, *Hist of Russia* (Rus), vol ix. (St Petersb 1895, etc).

PHILATELY. Postage stamps afford a simple and effective means of collecting fees paid, or required to be paid, for the transmission of matter sent by post. In 1653 the *petite poste* (local post) in Paris set up by M (afterwards Comte) de Villayer, as a private enterprise, but with royal sanction, sold letter-covers or wrappers bearing a distinctive mark, at two *sous* (one penny) each Letters enclosed in such wrappers and dropped in letter-boxes, were collected and delivered by *laquais* (footmen), who removed the wrappers on delivery. These wrappers were the first printed franks, comparable to the stamped envelopes and covers of modern times. In 1818 stamped sheets of paper served to collect a tax (not postage) on correspondence in Sardinia. Lieut. C. G. Treffenberg proposed stamped wrappers for the prepayment of postage in Sweden in 1823, but the plan was not adopted. Kindred proposals made in Great Britain (1830–39) prepared the way for the adoption of stamps to serve for the collection of postage under Rowland Hill's uniform postage plan in 1840. Two years in advance of Great Britain New South Wales issued embossed letter sheets, for penny local letters, and sold them at 1s. 3d. a dozen; they were not popular even when reduced to 1s a dozen.

Introduction of Postage Stamps.—The two kinds of stamps issued in Great Britain in 1840 were: (1) A stamped envelope or wrapper bearing a design by Wm Mulready R A., (2) adhesive postage stamps, small rectangles of paper, with the device of the queen's head, backed with gum The Mulready covers and the 1d. and 2d. adhesive postage stamps all came into use on May 6, 1840, some were sold on May 1, but they were not authorized for use before May 6. By May 12, Rowland Hill recognized that the covers were not in great demand. Stocks of the Mulready envelopes and letter-sheets were withdrawn and destroyed when new and simpler envelopes and sheets bearing the embossed stamp of the queen's head were issued in 1841

Adhesive postage stamps, owing to their small size and great variety, are the chief interest of the stamp-collector. The 1d. black and 2d blue stamps of Great Britain, 1840, bear a design ¾ in. wide by ⅞ in. high, printed from engraved steel plates. The queen's head was drawn by Henry Corbould from Wm Wyon's "City Medal" The engraving of this on steel was entrusted to Charles Heath, but was probably executed by his son Frederick Heath The die was transferred to steel plates, each of 240 repetitions, and from these plates, Perkins, Bacon and Petch, afterward Perkins, Bacon and Co. Ltd , printed the stamps The addition of perforations is due to an Irish inventor, Henry Archer, in 1854

The two stamps were subjected to changes in 1841, the 1d. being then printed in red instead of black, as the black stamps did not afford sufficient safeguard against the removal of postmarks The change in the 2d. blue consisted in the introduction of uncoloured lines under the words "postage" and "twopence "

Spread of the Stamp System.—Britain's first stamps attracted attention abroad, but a considerable period elapsed before the system was adopted extensively. A private "City Despatch Post" of New York, conducted by an Englishman, Henry T. Windsor, issued a 3 cent stamp in 1842. The Swiss cantons of Zurich and Geneva, and Brazil followed in 1843 The first Geneva stamp was a divisible one, the whole being used on cantonal letters (10 centimes) and the half for local postage within one commune Brazil's first stamps, known to collectors as "bulls-eyes" (the designs are elliptical), bear large numerals of value, proposals to use the effigy of Dom Pedro being abandoned as it was thought obliterating the portrait would show a want of respect for that sovereign The canton of Basle, and several postmasters in the United States issued stamps in 1845 The postmasters of New York and St. Louis issued adhesive stamps for the convenience of their customers, and to increase their incomes (which depended on postage collections); and the postmaster of New New Haven, Conn , issued stamped envelopes Other postmasters followed their example before the U S. Government issued postage stamps in 1847. Some of the "postmasters' stamps" are of the greatest rarity, notably those of Alexandria, Va , Annapolis, Md , Baltimore, Md , Boscawen, N H., Brattleboro, Vt., Lockport, N.Y , Millbury, Mass , New Haven, Conn , and St. Louis, Mo

In 1847 the first British colony to follow England's lead was Mauritius, where a local watchmaker engraved the earliest stamps on the back of a small copper plate, which had been used as an advertisement card for a local hotel Those were the 1d orange-red and 2d blue stamps lettered "Post Office" at the left side, and bearing the effigy of the queen, fewer than 30 copies of the two stamps are known The United States issued its first governmental postage stamps on July 1, 1847; the 5 cent stamp bore the effigy of Franklin, and the 10 cent that of Washington

In 1848 the postmaster of Bermuda issued a stamp, after the manner of the U S postmasters The next two years witnessed the extension of the system in Europe and elsewhere with stamps from Bavaria, Belgium, France (1849), Austria, British Guiana, Hanover, New South Wales, Prussia, Saxony, Schleswig-Holstein, Spain, Switzerland, Victoria (1850). Every year (1851–1909) new countries or colonies were added to the list, and no country with any claims to organized government is without postage stamps of some kind.

The Extensive Field for Collections.—Postage stamps were already attracting collectors in the '50s; by 1860–62 a great

wave of popular interest spread in Europe and America, and the extensive literature of stamp-collecting began. Mount Brown's catalogues published in 1862–64 list 1,200 varieties known to him in May 1862, and 2,400 in his last edition in March 1864. The *Standard Catalogue* (1928), which lists only main varieties of Government stamps, presents a total of 46,969. The more detailed catalogues, inclusive of minor varieties (Gibbons, Scott, Kohl, etc.) may be estimated as recording 170,000 to 180,000. Even these high figures refer only to adhesive postage stamps issued by Governments; if the stamps of municipal, local and private posts were added, the number would be much larger.

The first lists of postage stamps for the use of collectors were privately circulated in manuscript in 1860 by Oscar Berger-Levrault, a printer of Strasbourg, and in Aug. 1861 he issued a thin quarto 12-page list printed by autolithography. Alfred Potiquet, of Paris, had the benefit of these lists when he compiled his first catalogue, published in 1861. The earliest English catalogues (Booty, Mount Brown, Dr. Gray) appeared in 1862. Booty, a young artist, produced the first illustrated stamp catalogue (his 3rd ed.), pictures and text being drawn by himself on the lithographic stone (Aug. 1862). In America the first publication of the kind, A. C. Kline's *Stamp Collector's Manual* (Dec. 1862), was a pirated copy of Mount Brown's catalogue. Periodical literature began with the *Monthly Intelligencer* (Sept. 1862), but by 1863 journals which remain of reference value were started in the *Stamp Collector's Magazine* (England), *Timbre Poste* (Belgium) and *Magazin für Briefmarken-Sammler* (Germany). The first printed stamp albums were designed by a Frenchman, Justin Lallier, and published in France and England in 1862.

The development of the study of stamps, as distinct from mere collecting, dates from about 1867, when M. Berger-Levrault in *Les Timbres Poste, Catalogue méthodique et descriptif de tous les timbres-poste connus* gave details of dates of issue, methods of printing, shades, varieties of paper, watermark and perforation. These were the outcome of the "French school" of collecting, favoured by leading English and German collectors. The name philately had been given to the study in 1864, derived from the Greek φίλος (loving) and ἀτελής (free of tax), the intention of the originator, M. Herpin, being to indicate a fondness for things (stamps) exempt from tax.

Forming a Collection.—The vast output of stamps enables the beginner to start with a greater variety than was possible in the 19th century. Packets containing 1,000 to 10,000 different stamps are regularly stocked by dealers; they form the cheapest basis for starting a collection. The principal sources of supply for adding to collections are the stamp trade, auctions and exchange with other collectors. Stamps are arranged under countries, in the chronological order of issue. The loose-leaf album allows greater freedom for arrangement and expansion of the collection.

In addition to the stamp dealers established in many cities who hold large stocks of old and modern stamps for collectors, stamp auctions are held frequently in London, Paris, Berlin and New York, at which collectors and dealers bid in competition. An important source of supply of modern issues is the "Philatelic Agency," the first of which was started by the United States as a department of its post office at Washington (1921) to supply current stamps, and such stamps of older issues as may be available, at face value, to collectors and dealers; similar agencies were set up in Canada (Ottawa, 1923), the Canal Zone (Balboa Heights, 1924), Netherlands and colonies (Amsterdam, 1925), Denmark (Copenhagen, 1926), Sweden (Stockholm, 1927).

The stamps are generally removed from any back paper before mounting in the album; the mounting is done in a special way to permit the examination of a stamp, back and front, without removal from the album, and the removal of the stamp for transference to another place. This is done by means of hinges, consisting of small strips of paper, gummed on one side. This little strip, folded, gummed side outwards, forms the hinge, one arm of which is lightly fixed to the back of the stamp, while the other arm holds the stamp in position in the album.

Factors in stamps which the collector requires to examine are: (1) Paper, its colour, texture and watermark (if any); (2) design, subject, character of the impression (typographed, lithographed, engraved or embossed) and colour; (3) gum; (4) margins or gutters, with particular reference to the perforation (if any).

Watermarks in stamps are of great variety. In some cases an elaborate or large design is "watermarked in the sheet," and only part of it shows on a detached stamp. Where the watermarked devices are small, and correspond with the arrangement of the stamps in a sheet, they are "single watermarks." "Multiple" watermarks are small and separate devices as in the "single," but set so closely together that parts of two or more show in each stamp.

Perforations are punched out of the paper along the gutters between the stamps on a sheet. If instead of being punched out they are merely pricked by a wheel or raised printer's rule they are called "roulettes." Perforations and roulettes are measured on a system based on the number of perforations made in a length of 2 cm. (20 mm.). Thus, if a stamp be described as "perf. 12" it means that there are 12 perforations to the 2 cm. along any of its margins. To save counting a gauge is used consisting of a printed range of dots and lines set within a column 2 cm. wide. By running the stamp up or down this gauge it is easy to find a line where the dots fit neatly into the curves of the perforation; the number at the side denotes the perforation measurement.

The Scope of Philately.—The specialist seeks to show in his collection the full history of the stamps under consideration. Where obtainable he will show the artist's original drawings, engravers' and printers' proofs, colour trials, essays (proposed stamps which were submitted, but rejected, or altered before adoption). The principal portion of the collection, however, consists of the actual stamps as issued and used. Good condition of the specimens is of first importance. Unused stamps should be as near "mint" or "post-office" state as possible, that is to say, in the state they were in at the time of manufacture and issue. Used and unused stamps, especially old imperforate issues, are much sought after in unsevered pairs, strips or blocks, in which state they are often of added value. Used stamps of early date are of special interest if preserved on the original letter or envelope. The philatelist distinguishes successive printings or editions of stamps of one type by variations in shade, impression, paper, watermark or perforation. Postmarks, especially where they bear dates, help to place such editions in their proper sequence. Various phases of the use of the stamps are illustrated by postmarked copies, including, in many cases, stamps of one country used in another; *e.g.*, "British used abroad," also French, German, United States and other stamps used extra-territorially.

The World War provided interesting issues, like the British and other war issues for Samoa, New Britain, Baghdad, Bushire and Togo. The period of the armistice and post-war reconstruction brought many new countries within the sphere of philatelic interest, *e.g.*, Estonia, Latvia, Lithuania, Czechoslovakia, etc., and produced stamps which serve to recall the plebiscites, the mandated territories and the League of Nations; while in 1929, the issue of stamps which the Papacy formerly made, was restored.

With the advancement of aeronautical transport, mails are now regularly sent by air along many routes, and since Italy issued a special stamp for use on letters sent by an experimental air-mail between Rome and Turin in May 1917, the United States, Austria, Germany and many other countries have issued airpost stamps. In addition to interesting the general stamp collector, these have attracted new collectors who limit themselves to stamps of aeronautical associations. They pay particular attention to "flown covers," *i.e.*, letters or cards actually sent by air-mail. Such letters carried on historic flights like the transatlantic flights by Hawker (April 1919), Sir J. Alcock (June 1919), Marquis de Pinedo (1927) command high prices; there are elaborate special priced catalogues of air stamps (*see* Bibliography).

Expressions other than those used in a strict dictionary sense are: *Bisect,* half a stamp used as half the value of the whole stamp. *Block,* an unsevered group of stamps. *Control,* a letter or number, or both, on margin for checking purposes, or a device stamped on the front or back to prevent forgery or misuse. *Error,*

an incorrect stamp, either in design, colour or paper, etc. *Essay,* a proposed stamp, not adopted, or adopted only after some modification. *Imperforate* (imperf.), without perforation. *Local,* a stamp whose validity is limited to a town or district. *Mint,* in perfect unused condition (in the United States the same is described as *Post-office state*). *Pre-cancel* (*led*), stamps sold by the post-office already cancelled to firms mailing postal matter in bulk. *Reprint,* a fresh printing from original plates or stones after an issue has become obsolete. *Surcharge,* an overprint affecting the designation of value. *Tête-bêche,* an unsevered pair of stamps, one being upside-down.

National Collections.—The great collections founded by early collectors are all dispersed, except the important one which was the late T. K. Tapling's bequest to the British Museum. It is nearly complete up to 1890 in adhesive stamps and postal stationery. Only the adhesives are fully exhibited in the king's library at the museum, in cases with glazed, vertical slides, protected against deterioration from light and dust. Among the greatest rarities are: the full set and duplicates (12 in all) of the Hawaiian islands, Oct. 1, 1851, including the two types of the 2 cent ones, the second type being one of three copies known; British Guiana, 1851, 2 cent on rose used, 1856, 4 cent on dark blue (four copies); Mauritius, 1847, so-called post-office stamps, 1d. orange-red used on the original letter, 2d. blue unused, and an original document, being the engraver's estimate for making these stamps; Canada, 12d. black, an unused pair, and single copies, one used, one unused; Cape of Good Hope, 1d. and 2d., "wood-block" errors of colour; Ceylon, 4d. rose, imperforate; Moldavia, 17 copies of the first issue, including four of the 81 *parales;* Nevis, 1867, 1s. green on laid paper; India, 4 annas inverted frame; Western Australia, 4d. inverted swan. Great Britain occupies 55 slides of 220 large cards; the United States, 40 slides, including postmasters' stamps of Baltimore, Brattleboro, New Haven, St. Louis (10 copies), New York, and in the general issues all three values of the inverted centres of 1869 issue.

The Berlin postal museum contains an extensive collection with many rare items, including first issues of Mauritius, Hawaii and other celebrated rarities, but is especially strong in stamps, and documents relating thereto, of the old German States. Among its greatest rarities is one of three known copies of the 9 kreutzer Baden printed in black on green, instead of rose-coloured, paper. The Swedish Postal museum at Stockholm has an important collection, greatly extended by the generosity of Hans Lagerloef of New York, who in 1927 added the two denominations of the "post-office" Mauritius. A great collection of Dutch stamps forms the basis of a postal museum collection at The Hague. The U.S. national stamp collection, in the Smithsonian Institution, Washington, contains a fine historical collection of U.S. stamps, and representative collections of stamps of all countries. The New York public library acquired in 1924 a very complete collection of U.S. stamps collected by B. K. Miller, of Milwaukee. Other important public collections are installed at Dublin (Science and Art museum), Manchester (Whitworth Institute), Calcutta (Victoria Memorial Hall) Sydney, N.S.W. (Mitchell library), etc.

Famous Collectors and Their Collections.—King George V., patron and former president of the Royal Philatelic Society, London, started collecting stamps in his midshipman days, and his interest increased rather than abated in his later life. The King has a great range of rare specimens, original sketches, proofs, etc., including the unissued 2d. Tyrian plum, King Edward, and stamps overprinted for use of Government departments such as "I. R. Official" 1902–04, 6d. dull purple, 5s. carmine, 10s. ultramarine and £1 green, and "Board of Education" 1s. green and carmine, in singles and in pairs. Of every colony the royal collection is practically complete; Mauritius, with the two "post-office" stamps, 1d. used, and 2d. unused (the latter the finest copy known), is especially rich in rarities; British Guiana lacks only the 2 cents, 1850, and the 1 cent, 1856. The Barbados, Nevis, Hong Kong, Grenada, Bermuda, Trinidad, Turks islands and other portions of the King's collections have been shown at exhibitions or meetings.

The greatest private collection ever formed was that of Philippe la Rénotière von Ferrari, who died at Lausanne in 1917. The greater part of his collection was in Paris and was sequestrated by the French Government, and sold by auction in 1922–25. In 14 sales, covering 39 days, the stamps realized 26,482,964 francs or £402,965, calculated at the rate of exchange prevailing at the different periods of the sales. Many record prices were obtained for great rarities, among them:—British Guiana, 1856, 1 cent (unique), £7,343; 1850, 2 cents, pair £5,250; Hawaiian islands, 1851, 2 cents, £3,900; Mauritius, 1847, 2d., £2,338, 1d., £2,090; Baden, 9 kreutzer green (error) £1,816; France, 1849, 15 cents, *tête-bêche* pair £837, 1 franc (Vervelle) *tête-bêche* in a block of four, £2,706; United States postmasters' stamps: Boscawen, 1846, 5 cent (unique), £2,625, Lockport, 1846, 5 cent (unique), £1,875.

The most valuable collection of modern times is that of Arthur Hind of Utica, N.Y., who acquired a large proportion of the famous gems from the Ferrari sales, and has made extensive purchases in other directions; *e.g.,* Duveen collection of Mauritius, Griebert collection of Spain. He is the owner of the most celebrated stamps of which only single specimens are known; viz., British Guiana, 1 cent magenta, the Boscawen and Lockport postmasters' stamps; and in addition to two perfect unused "post-office" Mauritius (Duveen collection) he paid the record sum of £11,000 for an envelope on which the 1d and 2d. "post-office stamps" had been used together to prepay a 3d. rate of postage.

Organizations.—Philatelic societies are to be found in the chief cities of most countries. The Royal Philatelic Society, London, founded in 1869, was granted the prefix "Royal" by Edward VII. in 1906. The Junior Philatelic Society, founded in 1899, inaugurated a widespread movement which has extended throughout the world, assisting the beginner and medium collector; it organized the international philatelic exhibitions of London in 1912 and 1923. Between 70 and 80 societies in Britain and the colonies are affiliated in the Philatelic Congress of Great Britain, which meets annually. America has its similar institutions headed by the Collectors' club (New York), with flourishing societies in cities from Boston to San Francisco. The American Philatelic Society is a national body holding an annual convention; the Association for Stamp Exhibitions, Inc., organized the New York international exhibitions of 1913 and 1926.

BIBLIOGRAPHY.—The literature of philately is very extensive, and great libraries on the subject are accessible at the British Museum, London, the Collectors' club, New York, etc. *See* E. D. Bacon, *Catalogue of the Philatelic Library of the Earl of Crawford, K.T.* (1911), supplement (1926). The library is at the British Museum, bequeathed to the nation. *The Philatelic Index* to principal articles in philatelic journals, compiled by a committee of the Philatelic Congress of Great Britain (1925). General and introductory: A. B. Creeke, *Stamp Collecting: A Guide for Beginners* (1913); R. P. Croom-Johnson, *Postage Stamp Collecting: A Practical Guide* (1923); F. J. Melville, *Chats on Postage Stamps* (1920, bibl.); Philatelic Institute, *New A.B.C. of Stamp Collecting* (1922, bibl.), *Boys' Own Guide to Stamp Collecting* (1923); *Rare Stamps: How to Recognize Them* (1922) and *The Complete Philatelist* (1924, bibl.); F. B. Warren, *Pageant of Civilization* (1926). Advanced text-books (general); F. J. Melville, *Postage Stamps in the Making* (1916); A. J. Sefi, *An Introduction to Advanced Philately* (1926). Special groups: D. B. Armstrong, *British and Colonial Postage Stamps* (1920); T. Champion, *Catalogue historique des timbres de la Poste Aérienne* (1928); D. Ingram, *Postage Stamps of the Red Cross* (1919); F. J. Melville, *The Postage Stamp in War* (1914), *Aero Stamp Collecting* (2nd ed., 1924). Forgeries and Frauds: Rev. R. B. Earee, *Album Weeds* (1906), gives detailed descriptions of difference between genuine and forged specimens; F. J. Melville, *Phantom Philately* (1923), describes and illustrates bogus stamps; *i.e.,* stamps intended to deceive. *See* also the handbooks and pamphlets on stamps published in most countries, and the catalogues, illustrated and priced, published by dealers and revised annually or at frequent intervals; an up-to-date edition is indispensable as a guide to what stamps there are, and their approximate values. Collectors will use the catalogues published in their respective countries; viz., Stanley Gibbons, Bright and Son, Whitfield King and Co., in Great Britain and colonies; Scott Stamp and Coin Co., in the United States; Yvert-Tellier-Champion, in France and on the Continent in general; Senf, Michel and Kohl, in Germany; Galviz, in Spain and Spanish America, etc. (F. J. ME.)

PHILEMON (*c.* 361–263 B.C.), Greek poet of the New Comedy, was born at Soli in Cilicia, or at Syracuse. He settled at Athens early in life, and his first play was produced in 330

He was a contemporary and rival of Menander, whom he frequently vanquished in poetical contests. He lived at the court of Ptolemy, king of Egypt, for some time. Plutarch (*De Cohibenda Ira*, 9) relates that on his journey he fell into the hands of king Magas of Cyrene, whom he had formerly satirized. Magas treated him with contempt, and finally dismissed him with a present of toys. Various accounts of his death are given. Of ninety-seven plays, the titles of fifty-seven and considerable fragments have been preserved. Some of these may have been the work of his son, the younger Philemon.

See A Meineke, *Menandri et Philemonis reliquiae* (1823, including Bentley's emendations); T. Kock, *Com. graec. frag*, vol. iii (1884).

PHILEMON, EPISTLE TO, a New Testament book A short personal note by the apostle Paul has been preserved, which owes its origin to a romantic episode in the life of a slave, called Onesimus. For some reason he had run away from his master Philemon, a prosperous Christian citizen; it may be inferred that he had also been guilty of pilfering (ver. 18). For either offence he was liable by law to be crucified In some unexplained way he had come across Paul and been converted to Christianity This opened a difficult situation. The apostle boldly solved the problem by sending Onesimus back along with Tychicus, who was going to Colossae with Paul's letter to the local church; "I send him with Onesimus, that faithful and beloved brother, who is one of yourselves" (Col iv 9). But, not content with this certificate in favour of the converted and penitent slave, Paul sends also a note to his master, bespeaking his Christian interest in Onesimus It is a brief letter, tactful and charming, in which the apostle, after greeting Philemon and his wife and the local church that met in his house, rejoices over Philemon's character, which, he says, emboldens him to enter a plea for poor Onesimus, now returning to his duty, a very different man from what he was when he ran away Paul delicately suggests that he would like to have kept the slave beside him, and offers to be responsible for any debts incurred by Onesimus. He hints that this generous action on the part of Philemon will be a personal kindness to himself as well as to the slave "You count me a partner? Then receive him as you would receive me, and if he has cheated you of any money or owes you any sum, put that down to my account. This is in my own handwriting 'I Paul promise to refund it'—not to mention that you owe me, over and above, your very soul. Come, brother, let me have some return from you in the Lord Refresh my heart in Christ."

Where the letter was written, we do not know Rome was a natural place of refuge for runaway slaves, who could lose themselves in the huge population easily, if Colossians was written from Rome, so was this note. Where Philemon stayed is also uncertain; he may have been resident at Laodicea or at Ephesus, for though Onesimus accompanied the letter to the Colossian church, it does not follow that Colossae was the seat of his master; indeed as Philemon was converted by Paul, that cannot have taken place at Colossae, which Paul had never visited Still, Philemon may have shifted his quarters to Colossae

The letter appears in two second century canons, that of Marcion and the Muratorian, though its lack of dogmatic importance as well as its brevity threw it afterwards into some disfavour among certain circles of the Church

Bibliography —The letter is edited in most commentaries on Colossians (*q v*), and by Dr M R Vincent in his edition of Philippians (*International Critical Commentary*, 1897) There are special editions by Rothe (*Pauli ad Philemonem epistolae interpretatio historico-exegetica*, Bremen, 1844), van Oosterzee (Eng Tr New York, 1868), Oesterley (*Expositor's Greek Testament*, 1910), and others The social problems of the letter are discussed by Lightfoot in his Commentary on Colossians; by J. H. Bernard in Hastings' *Dictionary of the Bible* (iv. 832f), and in Renan's *L'Antéchrist* (pp 95 f). (J. Mof.)

PHILEMON AND BAUCIS, in Ovid (*Metam.*, viii. 610 ff.) a pious Phrygian couple, who hospitably received Zeus and Hermes (for their combined cult in Lycaonia cp. *Acts*, 14, 12), when their richer neighbours turned them away, they being disguised as wayfarers. As a reward, they were saved from a flood which drowned the rest of the country; their cottage was turned into a temple, and at their own request they became priest and priestess of it, and long after ended their lives at the same moment, being turned into trees. The story which is a *Märchen* of a well-known type, *e.g.*, *Grimm Kinder- und Hausmärchen*, 87, with the commentary of Bolte-Polivka, combined here with a version of the flood-myth, is perhaps really of local origin, *see* Calder in *Discovery*, 1922, p. 207 ff.

PHILES, MANUEL (*c.* 1275–1345), of Ephesus, Byzantine poet. At an early age he removed to Constantinople, where be was the pupil of Georgius Pachymeres, in whose honour he composed a memorial poem. Having offended one of the emperors by indiscreet remarks published in a chronography, he was thrown into prison and only released after an abject apology. Philes' character, as shown in his poems, is that of a begging poet, always pleading poverty, and ready to descend to the grossest flattery

Editions. the natural history poems in F. Lehrs and F. Dübner, *Poetae bucolici et didactici* (Didot series, 1846); *Manuelis Philae Carmina inedita*, ed A Martini (1900), *Manuelis Philae Carmina*, ed E Miller (1855–57). *See* also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

PHILETAS of Cos, Alexandrian poet and critic, flourished in the second half of the 4th century B C. He was tutor to the son of Ptolemy I of Egypt, and to Theocritus and the grammarian Zenodotus. His thinness made him an object of ridicule, according to the comic poets, he carried lead in his shoes to keep himself from being blown away. His elegies, chiefly singing the praises of his mistress Battis (or Bittis), were much admired by the Romans. Philetas was also the author of a vocabulary called Ἀτακτα, explaining the meanings of rare and obscure words, and of notes on Homer, severely criticized by Aristarchus

Fragments cited by N Bach (1828) and T. Bergk, *Poetae Lyrici Graeci; see* also E. W Mande, *De tribus Philetae carminibus* (1895)

PHILIDOR, FRANÇOIS ANDRE DANICAN (1726–1795), French composer and chess-player, was born at Dreux, on Sept. 7, 1726 He spent many years in travelling on the Continent and in England, meeting and defeating the most noted players of the time, and was regarded as the strongest player and greatest theoretician of the 18th century. Returning to France in 1754, he devoted himself seriously to music, and after producing several works of minor importance brought out at Paris, in the year 1759, his successful light opera, *Blaise le Savetier*, which was followed by a number of others. He died in London on Aug 31, 1795.

PHILIP, one of the 12 apostles *See* Apostle

PHILIP, "the evangelist," is mentioned in Acts vi. 5, as one of "the seven" chosen to superintend certain secular business of the Jerusalem Church, in consequence of dissension between the Aramaic-speaking and Greek-speaking disciples. Luke by mentioning the common meals wishes his readers to connect these officials with the later diaconate, but they seem to have been originally parallel among the Hellenistic Jews to the Twelve among the Hebraists Philip's was a ministry of the word He went to Samaria and preached with much success, Simon Magus being one of his converts. He afterwards instructed and baptized the Ethiopian eunuch on the road from Jerusalem to Gaza. His missionary journey ended at Caesarea (Acts viii). Here he entertained Paul and his companions on their last journey to Jerusalem (xxi. 8). (W. K. L. C)

PHILIP I. (1052–1108), king of France, eldest son of Henry I of France and Anne, daughter of Jaroslav I. (d 1054), grand duke of Kiev, came to the throne, when a child of eight, by the death of his father on Aug. 4, 1060. He had been crowned at Reims May 23, 1059 His minority came to an end in 1066. In the long reign that followed he showed no great ability or energy, and a looseness of morals which embroiled him with the Church Before he was fifty years of age he became "fond of nothing but good cheer and sleep." But he increased the lands of his house around Paris, maintained order in them, and held his own against William I. and William II. of England, whose power in France far exceeded his own. This he accomplished for the most part by taking advantage of the quarrels among his vassals. During the years 1070–74 he greatly strengthened his position in Flanders by these means. In the struggle between Fulk Rechin and his brother Geoffrey the Bearded for the inheritance of their uncle, Geoffrey Martel (d. 1060), count of Anjou, Philip received

rom Fulk in 1069, as the price of his neutrality, Château Landon ınd the Gatinais. This acquisition linked the county of Sens, ıcquired in 1055, with the rest of the domain round Paris, Melun ınd Orleans. War with William I. and William Rufus was chronic ɔut intermittent. In his last years Philip left the duty of repelling hė attacks of his Norman and other enemies to his son Louis, ıssociating him with himself, as "king-designate," some time ɔetween May 24, 1098, and Sept. 25, 1100.

It was his second marriage which was the cause of Philip's ;reatest difficulties. On May 15, 1092, he carried off Bertrada, laughter of Simon, baron de Montfort, wife of Fulk Rechin, and ɔrepared to marry her, though his wife Bertha was still living. The bishops, headed by Ivo, bishop of Chartres, refused to attend he ceremony of marriage, but one was found to perform it. Philip's open simony had long been a cause of friction with the ɔapacy. When he added bigamy and adultery, Urban II. excomnunicated him. Philip was reconciled with the Church in 1104, ınd took an oath not to have any converse or society with Bertrada except in the presence of "non-suspect" persons. But hey seem to have gone on living together, and even visited Fulk Rechin (Bertrada's husband) in company on Oct. 15, 1106. Philip lied at the end of July 1108.

His reign is chiefly remarkable for the steady growth of the ·oyal domain. By his first queen he had four children: Louis VI., who succeeded him; Henry, who died young; Charles; and Con- stance, who married Hugh I., count of Champagne, and later Bohemund I., prince of Antioch. By Bertrada de Montfort he had hree children: Philip, count of Montes; Fleury or Florus, who narried the heiress of Nangis; and Cecilia, who married, first Tancred, prince of Galilee and Antioch, and secondly Pons de Saint Gilles, count of Tripoli.

See the *Recueil des actes de Philippe I.*, ed. M. Pron (1908), and B. Monod's *Essai sur les rapports de Pascal II. avec Philippe I.* (Paris, 1907). For notices of the principal chronicles of the time *see* A. Molinier, *Les Sources de l'histoire de France* (II., esp. p. 307 *et seq.*).

PHILIP II. (1165–1223), known as PHILIP AUGUSTUS, king ɔf France, son of Louis VII. and Adela, daughter of Theobald II., count of Champagne, was born on Aug. 21, 1165. On Nov. 1, 1179, he was associated with his father as king by being crowned ıt Reims, and at once his father's illness threw the responsibility ɔf government on him, the death of Louis on Sept. 19, 1180, leavng him sole king. His long strip of royal domain was hemmed n by the Angevin Empire on the west and by the kingdom of Arles on the south-east. Henry II. of England was feudal lord ɔf the greater part of France, practically all west of a line which ɔegan at Dieppe and ended at the foot of the Pyrenees more han half-way across to the Mediterranean, while at one point t nearly touched the Rhone. Philip's predecessors had consoliated the Capetian power within these narrow limits, but he himself was overshadowed by the power of his uncles, William, archbishop of Reims; Henry I., count of Champagne; and Theobald V., count of Blois and Chartres. He secured an ally against them, ınd an addition to the royal domain, by marrying, on April 28, 1180, Isabella or Elizabeth, daughter of Baldwin V., count of Hainaut, and of Marguerite, sister of Philip of Alsace, the reigning count of Flanders, who ceded, as Isabella's dowry, the district ıfterwards called Artois. On June 28, 1180 Philip made a treaty with Henry II. at Gisors, but from 1181 to 1185 he had to struggle against a feudal league of his Champagnard uncles and other great barons, whose most active member was Stephen I., count of Sancerre (1152–1191). Having secured his position at home, the king turned against Henry II., and by the truce of Châteauroux in June 1187, gained Issoudun and the seigniory of Fréteval in the Vendômois. Though the truce was for two years, Philip assembled an army in 1188 to invade Normandy, demanding Gisors and the conclusion of the marriage which had been arranged between his sister Alice and Richard of England, who had meanwhile deserted his father. But Richard took the cross, and Philip seized the county of Berry, part of his dukedom. Further reconciliations and conferences followed, and Henry II., just before his death, did homage and surrendered the territories of Graçy and Issoudun. Henry died two days later. Pledges of mutual good faith and fellowship were exchanged between Philip and Richard of England on Dec. 30, 1189, and they both prepared to go on the crusade.

The Crusade.—Before setting out Philip arranged for the government of France during his absence by the testament of 1190, by which he proposed to rule France as far as possible from Palestine. On the way to Palestine the two kings quarrelled. At the siege of Acre Philip fell ill, and he returned to Paris at Christmas 1191, having concluded on his way an alliance with the emperor Henry VI. against Richard, despite his pledges not to molest his lands. Philip did his utmost by offers of money to prolong Richard's captivity, and, allied with the English king's brother John, attacked Richard's domains. But upon Richard's return the Normans rallied to him, and Philip was defeated at Fréteval on July 3, 1194. He continued the war, generally with ill success, for the next five years. Again a formidable coalition was formed against him, including Baldwin IX., count of Flanders and Hainaut, Renaud of Dammartin, count of Boulogne, Louis, count of Blois, and Raymond VI., count of Toulouse. In Germany, Otto of Brunswick, afterwards the emperor Otto IV., allied himself with Richard, while Philip was supported by Otto's rival, Philip of Swabia. Richard's death, in April 1199, removed his archenemy, and Richard's successor, John, concluded the treaty of Le Goulet with Philip on May 22, 1200, ceding to him the county of Evreux, Graçy and Issoudun, and the suzerainty of Berry and Auvergne. John renounced his suzerainty over Brittany and the guardianship of his nephew, Arthur; he engaged not to aid the count of Flanders or Otto IV. without Philip's consent, paid him a relief of 20,000 marks, and recognized himself as his vassal for his continental fiefs.

Conquest of Normandy.—But in 1202 the war was renewed. At an interview at Le Goulet on March 25, Philip demanded the cession of Anjou, Poitou and Normandy to his ward, Arthur. John refused; he was summoned to Paris before the royal judges, and failing to appear was sentenced at the end of April 1202 to lose all his fiefs. Brittany, Aquitaine and Anjou were conferred on Arthur. Philip invaded Normandy, took Lyons-la-Forêt and Eu, and, establishing himself in Gournay, besieged Arques. But John, joined by William des Roches and other lords of Maine and Poitou, jealous at the increase of Philip's power, defeated and took Arthur prisoner at Mirebeau. Philip abandoned the siege of Arques in a fit of fury, marched to the Loire, burning everywhere, and then returned to Paris. But John soon alienated the Poitevin barons, and William des Roches signed a treaty with Philip on March 22, 1203. Then Philip continued his great task, the conquest of Normandy, capturing the towns around the fortress of Château-Gaillard which Richard had built to command the valley of the Seine. Pope Innocent III. tried to bring about peace, but Philip was obdurate, and after murdering Arthur of Brittany John took refuge in England in December 1203. The fall of Château-Gaillard, after a siege which lasted from September 1203 to April 1204, decided the fate of Normandy. Rouen, bound by ties of trade to England, resisted for forty days; but it surrendered on June 24, 1204 The conquest of Maine, Touraine, Anjou and Poitou in 1204 and 1205 was little more than a military promenade, though the castles of Loches and Chinon held out for a year. Philip secured his conquest by lavishing privileges on the convents and towns. He left the great lords, such as William des Roches, in full possession of their feudal power. In 1206 he marched through Brittany and divided it amongst his adherents. A truce for two years was made on Oct. 26, 1206, by which John renounced all claims in Normandy, Maine, Brittany, Touraine and Anjou, but it did not last six months. Then Poitou was thoroughly subdued, and another truce was made in 1208, little more than southern Saintonge and Gascony being left in the hands of John. Philip had reduced to a mere remnant the formidable continental empire of the Angevins, which had threatened the existence of the Capetian monarchy.

Philip then undertook to invade England. He had collected 1,500 vessels and summoned all his barons when Innocent III., having sufficiently frightened John, sent Pandulf with the terms of submission, which John accepted on the 13th of May.

Disappointed of his hopes of England, Philip turned his arms against Ferdinand, count of Flanders. He invaded Flanders and took the chief towns within a week; but he had part of his fleet burned by the English at Damme, and had to burn the rest to save it from falling into their hands. He returned to Paris, and Ferdinand retook most of the towns which had been taken by the king. A war of fire and pillage began, in which Philip and his son Louis burned their way through Flanders, and Ferdinand did the same through Artois.

The Victory of Bouvines.—In 1214 came the great crisis of Philip's life. A league including his rebel vassals, Renaud of Dammartin, count of Boulogne, and Ferdinand, count of Flanders, with the emperor Otto IV. and a number of German princes of the Rhine region, had been formed in the north-east, while John of England made one more attempt to recover his heritage at the head of an army of mercenaries, aided by the fickle baronage of Poitou. John landed at La Rochelle on Feb. 10, 1214, and was at first successful. On June 19 he laid siege to La Roche-aux-Moines, the fortress which defended Angers and commanded the Loire valley; but on the approach of a royal army under Prince Louis on July 2 his Poitevin barons refused to risk a pitched battle, and he fled hastily to La Rochelle. The Angevin Empire in France was lost. Meanwhile Philip himself won his greatest victory at the bridge of Bouvines, among the morasses of Flanders. At first taken by surprise, he turned the abortive attack into a complete rout. Renaud and Ferdinand were taken prisoner, and Otto IV. fled from the battlefield. The army of the allies was utterly destroyed (July 27, 1214). The battle of Bouvines, a decisive battle for the history of Germany as well as for France and England, sealed the work of Philip Augustus. The expedition of his son Louis to conquer England can hardly be considered as an incident of his reign, though he was careful to safeguard the rights of the French Crown. More important was the Albigensian crusade, in which he allowed Louis to take part, though he himself, preoccupied with the king of England, had refused time after time to do anything. He treated Simon de Montfort as if he were a royal *bailli;* but it was not in virtue of any deep-laid scheme of his that in the end Amaury de Montfort, Simon's son, resigned himself to leave his lands to the Crown of France, and gave the Crown a power it had never before possessed in Languedoc.

Organisation of France.—Philip II. surrounded himself with clerks and legists of more or less humble origin, who gave him counsel and acted as his agents. His *baillis,* who at first rather resembled the itinerant justices of Henry II. of England, were sent into the royal domain to supervise the conduct of the *prévôts* and hear complaints, while in the south local feudal magnates were given similar powers with the title of *sénéchal.* Feudal service was more and more compounded for by a money payment, and additional taxes were raised. The extension of the system of *sauvegarde,* by which abbeys, towns or lay vassals put themselves under the special protection of the king, and that of *pariage,* by which the possessor surrendered half the interest in his estate to the king in return for protection or some further grant, increased the royal power. The small barons were completely reduced to submission, whilst the greater feudatories could often appoint a castellan to their own castles only after he had taken an oath to the king.

It has been said with some justice that Philip II. was the first king of France to take the bourgeoisie into partnership. He favoured the great merchants, granting them trade privileges and monopolies. The Jews he protected and plundered by turns, after the fashion of mediaeval kings. Amongst the subject towns administered by *prévôts* a great extension of the "custom of Lorris" took place during his reign. Philip was the ally and protector of the communes. Before him they were resisted and often crushed; after him they were exploited, oppressed, and finally destroyed. In the case of Senlis he extended the jurisdiction of the commune to all crimes committed in the district. It is true that he suppressed some communes in the newly conquered fiefs, such as Normandy, where John had been prodigal of privileges, but he erected new communes in his own private domain, quite contrary to the custom of other kings. He seems to have regarded them as a kind of garrison against feudal unruliness, while the rents they furnished increased his financial resources. He created no new types of commune, however, except Peronne, which received a maximum of political independence, the twenty-four electors, who named the *jurés* and other officers, being elected by the *corps de métiers.*

Philip's policy of building up a strong monarchy was pursued with a steadiness of aim which excluded both enthusiasm and scruple. He shrank from no trickery in carrying out his ends, and had no room for pity. He could not even trust his own son with any power, and was brutal in his relations with his queen, Ingeborg. As the result of his steadiness of aim and patient sagacity, at the end of his reign the Crown was victorious over the feudal nobility and the royal domain extended to the frontiers along with royal authority. Artois, the Amienois, Valois, Vermandois, the greater part of the Beauvaisis, Normandy, Maine, Anjou, Touraine, and an important part of Poitou and Saintonge, were added to the domain during his reign. The number of *prévôtés* was increased from thirty-eight to ninety-four, and the royal revenue increased from 19,000 livres a month to 1,200 livres a day.

Philip Augustus died on July 14, 1223. He was thrice married. His first wife, Isabella, by whom he had one son, Louis, died in 1189 or 1190. After her death he married Ingibjörg or Ingeborg (*q.v.*), daughter of Valdemar I. of Denmark, whom he soon repudiated. In 1196, in defiance of the pope, he married Agnes, daughter of Bertold IV., duke of Meran. This led to his excommunication and brought the interdict upon France, and did more to weaken him than any other act of his. In 1200 he was forced to put away Agnes and to recognize Ingeborg as his lawful wife, but he kept her in prison until 1213. By Agnes (d. 1201) he had a son Philip, called "Hurepel," count of Clemont, and a daughter Mary, who married Philip, count of Namur (d. 1213), and then Henry II., duke of Brabant. Ingeborg lived until 1236.

See A. Luchaire in E. Lavisse's *Histoire de France,* tome iii. 83–284 (Paris, 1904), and literature there indicated; L. Deslisle, *Catalogue des actes de Philippe Auguste* (Paris, 1856 and 1901); A. Cartellieri, *Philipp II. August,* Bd. I. *Bis zum Tode Ludwigs VII.* (Leipzig, 1899), Bd. II *Der Kreuzzug* (1906); and W. H. Hutton, *Philip Augustus* (in the Foreign Statesmen series, London, 1896). A. Molinier, *Les Sources de l'histoire de France* (tome iii. pp. 1–38), gives a complete bibliography of the sources for Philip's reign, including the history of the Third Crusade.

PHILIP III. (1245–1285), surnamed "the Bold" (*le Hardi*), king of France, son of Louis IX. and Margaret, daughter of Raymond-Bérenger IV., count of Provence, was born on April 3, 1245. His funeral monument at St. Denis depicts a man with beardless, square-cut features, but lacking character and animation. The authenticity of this effigy is fairly well borne out by what is known of him from other sources. He had many of the virtues of St. Louis, but neither decision of character nor devotion to duty. He was pious, charitable, of unimpeachable morality, quick-tempered but placable, no great scholar, and only energetic as a hunter. The absence in him of the qualities that fit a man to rule made his court the arena of intriguing factions, which in reality ruled France during his reign of fifteen years. Matthew of Vendôme, abbot of St. Denis, an old servant of Louis IX., acted as Philip's counsellor, so the chroniclers state, throughout the reign; but it was probably with administration, and not policy, that Matthew was chiefly concerned. Philip began his reign in 1270 by falling entirely under the influence of Pierre de la Brosse, who had been surgeon and valet-de-chambre to his father whom he made lord (sieur) of Langeais, Chatillon-sur-Indre and Damville. His influence lasted until Philip's second marriage in 1274 with Marie, daughter of Henry III., duke of Brabant. She supplied a centre for the enemies of the favourite, who, in 1278, was charged with various crimes, including one of poisoning the king's eldest son, and hanged at Montfaucon. His death left the parties of Marie, the queen, and Margaret, the queen-mother, to struggle for the mastery. The settlement of the claims of the king of England in Aquitaine by the treaty of Amiens in 1279 was a victory for the party of Margaret.

Agenais and southern Saintonge, which fell to the Crown by

the death of Alfonse of Poitiers in 1276, as part of his vast possessions in Aquitaine and Languedoc, were ceded to Edward I. of England in accordance with the treaty of Paris in 1259. Another portion of the heritage of Alfonse, the Venaissin, was ceded to the papacy to redeem an old promise. In general the strong will of Charles of Anjou directed Philip's policy. He secretly urged his nephew's candidature for the imperial crown, left vacant by the death of Richard of Cornwall, king of the Romans, in 1272, but without success. In May 1275 the party of Marie secured for Philip, the king's second son, the hand of Jeanne, the heiress of Navarre and Champagne, along with the guardianship of the kingdom of Navarre during the minority of Jeanne. But early in 1276 Jeanne's mother, Blanche, the widow of Henry III. of Navarre and Champagne, married Edmund, first earl of Lancaster, brother of Edward I.; and she and her English husband kept Champagne until, in 1284, Jeanne came of age.

An expedition of Philip against Castile in aid of the children of his sister, Blanche, proved abortive Regardless of this warning, he was induced in 1284 to take up the quarrel of his uncle Charles in Sicily, after the Sicilian Vespers in 1282. Two assemblies of barons and prelates were held at Bourges in November 1283 and February 1284 to deliberate on the question This was a mere matter of form; Marie of Brabant and her party had decided the matter beforehand, and the crown of Aragon, which the French pope Martin IV had declared forfeited by Peter, was accepted for Charles of Valois, Philip's third son The project was strongly opposed by Matthew of Vendôme, who was in correspondence with the king of England on the subject It was the first warlike expedition undertaken by the house of Capet outside France It proved a disastrous failure. Philip died during a retreat from Gerona on Oct 5, 1285

Philip was twice married On May 28, 1262 he married Isabella, daughter of James I, king of Aragon, who died in 1271. By her he had four children. Louis, who died in 1276; Philip, born in 1268; Charles of Valois, born on March 12, 1270; and Robert, who died young By his second wife, Marie (d 1322), daughter of Henry III of Brabant, whom he married in 1274, he had three children: Louis, count of Evreux; Margaret, who married in 1299 Edward I, king of England; and Blanche, who married Rudolph III, duke of Austria

PHILIP IV. (1268–1314), called *"le Bel"* or "the Fair," king of France, was the son of Philip III and his wife, Isabella of Aragon His reign, which began in October 1285, is one of the most momentous in the history of mediaeval Europe, yet it belongs rather to the history of France and to that of the papacy than to the biography of the king. Little is known of the personal part played by Philip in the events associated with his name, and later historians have been divided between the view which regards him as a handsome, lethargic nonentity and that which paints him as a master of statecraft who, under a veil of phlegmatic indifference and pious sentiment, masked an inflexible purpose, of which his ministers were but the spokesmen and executors. The first view seems to be borne out by the language of contemporary chroniclers Yet this was the king who brought the papacy under his yoke, carried out the destruction of the powerful order of the Temple, and laid the foundations of the national monarchy of France In this last achievement Finke finds the solution of a problem which Langlois had declared to be insoluble. In 1302, in the midst of a hostile assembly, Philip cursed his sons should they consent to hold the Crown of any one but God[1]; and in this isolated outburst he sees the key to his character. "Philip was not a man of violent initiative, the planner of daring and fateful operations; otherwise there would have been some signs of it. His personality was that of a well-instructed, outwardly cold, because cool and calculating man, essentially receptive, afire for only one idea. the highest possible development of the French monarchy, internally and externally, as against both the secular powers and the Church. His merit was that he carried through this idea in spite of dangers to himself and to the state. A resolution once arrived at he carried out with iron obstinacy" Certainly he was no *roi fainéant.* His courage at the battle of Mons-en-Pévèle was the admiration of friend and foe alike. It was against the advice of his tutor, Aegidius Colonna, that on coming to the throne he chose as his counsellors men of the legal class, and the names of his great ministers—Guillaume de Nogaret, Enguerrand de Marigny, Pierre Flotte (d. 1302)—attest the excellent quality of his judgment He was, too, one of the few monarchs who have left to their successors reasoned programmes of reform for the state

The greatest event of the reign was the struggle with Pope Boniface VIII. (*q v*). The pope went so far in 1296 as to forbid any lay authority to demand taxes from the clergy without his consent. When Philip retaliated by a decree forbidding the exportation of any coin from France, Boniface gave way to save the papal dues, and the bulls issued by him in 1297 were a decided victory for the French king There was a truce until 1301. After the arrest, by Philip's orders, of Bernard Saisset (*q v*), bishop of Pamiers, in that year, the quarrel flamed up again. To ensure the support of his people the king had called an assembly of the three estates of his kingdom at Paris in April 1302; in the following year Guillaume de Nogaret seized the person of the pope at Anagni, an event immortalized by Dante Boniface escaped from his captors only to die (Oct 11), and the short pontificate of his saintly successor, Benedict XI, was occupied in a vain effort to restore harmony to the Church. The issue of the conclave that met at Perugia on his death was ultimately determined by the diplomacy and gold of Philip's agents, and the new pope, Clement V, was the weak-willed creature of the French king When in 1309 the pope installed himself at Avignon, the new relation of the papacy and the French monarchy was patent It was the beginning of the "Babylonish captivity" of the popes. The most notable of its first-fruits was the hideous persecution of the Templars (*q v*), which began with the sudden arrest of the members of the order in France in 1307, and ended with the suppression of the order by Pope Clement at the council of Vienne in 1313

In 1294 Philip IV attacked Edward I of England, then busied with the Scottish War, and seized Guienne Edward won over the counts of Bar and of Flanders, but they were defeated and he was obliged to make peace in 1297 Then the Flemish cities rose against the French royal officers, and utterly defeated the French army at Courtrai in 1302 The reign closed with the French position unimproved in Flanders, except for the transfer to Philip by Count Robert of Lille, Douai and Béthune, and their dependencies Philip died on Nov 29, 1314 His wife was Jeanne, queen of Navarre (d 1304), through whom that country passed under the rule of Philip on his marriage in 1284; three of his sons, Louis X., Philip V. and Charles IV, succeeded in turn to the throne of France, and a daughter, Isabella, married Edward II. of England.

PHILIP V. (*c.* 1294–1322), "the Tall," king of France, second son of Philip the Fair and Jeanne of Navarre, received the county of Poitiers as an appanage, and was affianced when a year old to Jeanne, daughter and heiress of Otto IV., count of Burgundy. The marriage took place in 1307 when he was thirteen years of age. When his elder brother, Louis X., died, on July 5, 1316, leaving his second wife, Clemence of Hungary, with child, Philip was appointed regent for eighteen years by the parliament

of Paris, even in the event of a male heir being born. Clemence's son lived only four days, and Philip proclaimed himself king (Nov. 19, 1317). The barons all did homage except Edward II. of England, and Philip's position was secured. The war with Flanders, which had begun under Philip IV. the Fair, was brought to an end on June 2, 1320. The revolt of the Pastoureaux who assembled at Paris in 1320 to go on a crusade was crushed by the seneschal of Carcassonne, whither they marched. One of the special objects of their hatred, the Jews, were also mulcted heavily by Philip, who extorted 150,000 livres from those of Paris alone. He died at Longchamp on the night of Jan. 2, 1322.

Philip was a lover of poetry, surrounded himself with Provençal poets and even wrote in Provençal himself, but he was also one of the most hard-working kings of the house of Capet. The insecurity of his position made him seek the support of national assemblies and of provincial estates. He published a series of ordinances organizing the royal household and affecting the financial administration, the "parlement" and the royal forests. He abolished all garrisons in the towns except those on the frontier, and provided for public order by allowing the inhabitants of his towns to arm themselves under the command of captains. He tried hard to procure a unification of coinage and weights and measures, but failed owing to the opposition of the estates. Philip as a reformer was in many ways before his time, but his people failed to understand him, and he died under the reproach of extortion.

See P. Lehugeur, *Histoire de Philippe le Long* (Paris, 1897); E. Lavisse, *Histoire de France* (Tome III., 2); and sources indicated in A. Molinier, *Répertoire des sources de l'histoire de France* (Paris, 1903).

PHILIP VI. (1293–1350), king of France, was the son of Charles of Valois, third son of Philip III., the Bold, and of Margaret of Sicily, and was thus the nephew of Philip IV., the Fair, whose sons, Louis X., Philip V. and Charles IV., died successively without leaving male heirs. He succeeded to the throne on the death of his cousin, Charles IV., in 1328. Before his accession Philip had enjoyed considerable influence, for he was count of Valois, Anjou, Maine, Chartres and Alençon. He had married in 1313 Jeanne (d. 1348), daughter of Robert II. of Burgundy, a determined woman who was long known as the real ruler of France.

When Charles IV. died, in Feb. 1328, his wife was enceinte, and it became necessary to appoint a regency until the birth of the child, who would, if a son, succeed to the throne. At the assembly of barons called to choose a regent, Edward III. of England, the nephew and nearest male relation of Charles IV., put in a claim. Edward III., however, descended from the royal house of France by his mother Isabel, and the barons, probably actuated by an objection to the regency of an English king, decided that neither a woman, "nor by consequence her son, could succeed to the kingdom of France," and Philip of Valois, in spite of his belonging to a junior branch of the family, was elected regent. On the birth of a girl to the queen widow the regency naturally led to the throne of France, and Philip was crowned at Reims on May 29, 1328. Navarre had not accepted the regency, that kingdom being claimed by her husband for Jeanne, countess of Evreux, the eldest daughter of Louis X., the count of Evreux himself being, like Philip of Valois, a grandson of Philip the Bold. The new king secured the friendship of the count by allowing Jeanne's claim to Navarre, in return for a renunciation of any right to Champagne. Edward III. of England, after more than one citation, reluctantly fulfilled (1320–22) the formalities of homage for part of Guienne. Meanwhile Philip VI. had won a victory, which he turned into a massacre, at Cassel (Aug. 23, 1328) over Bruges and the other towns of West Flanders, which under the leadership of Jakob van Artevelde had thrown off the authority of their count, Louis of Nevers. The count of Flanders was reinstated, and maintained his authority by a reign of terror.

Philip VI. enjoyed powerful alliances. In Italy he was allied with his uncle, Robert of Anjou, king of Sicily, and with his former enemy, Galéas Visconti; in the north with the duke of Brabant and the princes of the Netherlands; on the east with the reigning princes of Lorraine and Savoy; with the king of Bohemia and with Pope John XXII. at Avignon, and his successor, Benedict XII. In 1336 it seemed that the Crusade, for which Philip VI. had long been preparing, would at last start; but the relations with Edward III. of England, always strained, became worse, and within a year France was embarked on the struggle of the Hundred Years' War. The causes which led to war, the conflict for commercial supremacy in Flanders, disputed rights in Guienne, the help given by France to the Scots, and the unnatural situation of an English king who was also a vassal of the French Crown are dealt with elsewhere. (*See* FRANCE: *History.*) The immediate rupture in Flanders was due chiefly to the tyranny of the count of Flanders, Louis of Nevers, whom Philip VI. had reinstated. Edward III. had won over most of Philip's German and Flemish allies, and the English naval victory at Sluys (June 24, 1340), in which the French fleet was annihilated, effectually restored English preponderance in Flanders. A truce followed, but this was disturbed after a short duration by the disputed succession to the duchy of Brittany (*q.v.*). A truce made at Malestroit in 1343, at the invitation of the pope, was rudely broken by Philip's violence. Olivier de Clisson, who with fourteen other Breton gentlemen was suspected of intrigue with Edward III., was invited to a great tournament in Paris. On their arrival they were seized by Philip's orders, and without form of trial beheaded. Then followed Edward III.'s invasion of Normandy and the campaign of Créçy (*q.v.*). Philip's army was destroyed; he himself was wounded and fled from the field. He sought in vain to divert Edward from the siege of Calais by supporting the Scots in their invasion of England; but eventually a truce was arranged, which lasted until 1351. Philip VI. died at Nogent-le-roi on Aug. 12, 1350.

Philip VI. met his necessities by the imposition of the hated gabelle or salt tax, which was invented by his legal advisers and he obtained heavy subsidies from the various provinces. Towards the close of his reign he acquired from Humbert II., comte de Vienne, the province of Dauphiné, and Montpellier from the king of Majorca. Philip married a second wife, Blanche of Navarre. By his first wife he left two sons—his successor, John II., and Philip of Orleans, count of Valois.

(1837), edition by Paulin Paris; E Déprez, *Les préliminaires de la guerre de cent ans, 1328–1342* (Paris, 1902), based on texts from the English Record Office and the Vatican; Paul Viollet, *Histoire des institutions politiques de la France* vol. ii. (Paris, 1898); and E. Lavisse, *Hist. de France*, vol. iv. pt. i. (1902), by A. Colville. Further references will be found in Nos. 3,095–3,112 and 3,165–3,240 of A. Molinier's *Sources de l'histoire de France*, vol. iv. (Paris, 1904).

PHILIP (*c.* 1177–1208), German king and duke of Swabia, the rival of the emperor Otto IV., was the fifth and youngest son of the emperor Frederick I. and Beatrix, daughter of Renaud III., count of Upper Burgundy, and brother of the emperor Henry VI. He entered the church, was made provost of Aix-la-Chapelle, and in 1190 or 1191 was chosen bishop of Würzburg. Philip forsook his ecclesiastical calling and was made duke of Tuscany in 1195 receiving an extensive grant of lands. In 1196 he became duke of Swabia, on the death of his brother Conrad; and in May 1197 he married Irene, daughter of the eastern emperor, Isaac Angelus, and widow of Roger II., king of Sicily. Philip appears to have been designated as guardian of the young Frederick, afterwards the emperor Frederick II., in case of his father's early death. In 1197 he had set out to fetch Frederick from Sicily for his coronation when he heard of the emperor's death and returned at once to Germany. He found growing hostility to the kingship of a child, and the absence of the two Welf claimants, Otto and Henry, the sons of Henry the Lion, made possible Philip's own election as German king at Mühlhausen on March 8, 1198. He was crowned at Mainz on Sept. 8.

Meanwhile a number of princes hostile to Philip, under the leadership of Adolph, the archbishop of Cologne, had elected an anti-king in the person of Otto, second son of Henry the Lion, duke of Saxony. War followed, in which Philip drew his principal support from south Germany. In 1199 he received further accessions to his party and carried the war into his opponent's territory. In March 1201 Innocent III. placed Philip and his associates

under the ban, and began to work for Otto. Otto, aided by Ottakar I., king of Bohemia, and Hermann I., landgrave of Thuringia, drove him from north Germany, and compelled him to seek, in vain, reconciliation with Innocent. The submission of Hermann of Thuringia in 1204 marks the turning-point of Philip's fortunes, and he was soon joined by Adolph of Cologne and Henry I., duke of Brabant. On Jan. 6, 1205, he was crowned again by Adolph at Aix-la-Chapelle, though it was not till 1207 that his entry into Cologne practically brought the war to a close. Philip was then loosed from the papal ban. He was preparing to crush the last flicker of the rebellion in Brunswick when he was murdered at Bamberg, on June 21, 1208, by Otto of Wittelsbach, count palatine in Bavaria, to whom he had refused the hand of one of his daughters. He left four daughters, one of whom, Beatrix, afterwards married his rival, the emperor Otto IV. Philip was a brave and handsome man, and contemporary writers, among whom was Walther von der Vogelweide, praise his mildness and generosity

See O Abel, *König Philipp der Hohenstaufen* (1852); E. Winkelmann, *Philipp von Schwaben und Otto IV von Braunschweig* (Leipzig, 1873–78), *Regesta imperii V*, ed J. Ficker (Innsbruck, 1881); R Schwemer, *Innocenz III. und die deutsche Kirche während des Thronstreites von 1198–1208* (Strasbourg, 1882).

PHILIP I., king of Macedonia, a semi-legendary prince, son of Argaeus, was, according to Herodotus (viii 137–139) and Thucydides (ii 100), the third of the Macedonian kings There is, however, no real evidence for his existence.

PHILIP II. (382–336 B C), king of Macedonia, the son of Amyntas II and the Lyncestian Eurydice, reigned 359–336 At his birth the Macedonian kingdom, including the turbulent peoples of the hill country behind, was very imperfectly consolidated. In 370 Amyntas died, and the troubled reign of Philip's eldest brother, Alexander II, was cut short in 368 by his assassination His murderer, Ptolemy of Alorus, ruled as regent for the young Perdiccas, Amyntas's second son In 367 Philip was delivered as a hostage to the Thebans, then the leading power of Greece, where he got to know Epameinondas, whom he greatly admired and whose influence may be traced in Philip's military reforms When he returned to Macedonia (364) Perdiccas had succeeded in getting rid of Ptolemy, but he fell in 360–359 before an onslaught of the hill tribes instigated by the queen-mother Eurydice, leaving only an infant son Pretenders sprang up and the kingdom fell into confusion. Philip seized the throne and drove back his rivals He now began the great task of his life—the creation of the Macedonian national army. Cavalry, the famous "companions," he already had; his work was to produce an efficient force of infantry This new force of his making consisted of the *hupaspistai* who may have been peltasts on Iphicrates's model, and the phalanx, which in its use for shock tactics on the wing in conjunction with the cavalry shows the influence of Epameinondas, but was less densely packed, and was armed, unlike Greek troops, with a long pike The first experiment he made with this new organism was brilliantly successful. The hill tribes were broken by a single battle in 358, and Philip established his authority inland as far as Lake Ochrida. In the autumn of the same year he took the Athenian colony Amphipolis, which commanded the gold-mines of Mt. Pangaeus Their possession was all-important for Philip, and he set there a new city, Philippi Athens was temporarily pacified by assurances that Amphipolis would be handed over to her later on.

He avoided as yet a forward policy, and having taken Pydna and Potidaea soon after Amphipolis, he made them over to the Olynthian confederation (*see* OLYNTHUS) His marriage with the fierce witch-woman, Olympias, daughter of the Epirote king, falls in this period, and in 356 she bore him his greater son, Alexander In 353 Philip was ready for strong action. He first attacked Abdera and Maroneia, on the Thracian sea-board, and then took Methone, which belonged to Athens An overt breach with Athens was now inevitable. In the same summer he invaded Thessaly, where the Aleuadae of Larissa ranged themselves on his side against the *tagos* Lycophron, "tyrant" of Pherae. Pherae called in the help of the Phocian mercenaries, who had profaned Delphi, and Philip was twice heavily defeated. But next year the Macedonian army won a complete victory over the Pheraeans and Phocians. This battle made Philip *tagos* of Thessaly, and he annexed Magnesia, which included Pagasae But on advancing further he found the Athenian expedition which had failed to secure Pagasae holding Thermopylae, and withdrew. From 352 to 346 Philip did not again come south. He was active in completing the subjugation of the Balkan hill-country to the west and north, and in reducing the Greek cities of the coast as far as the Hebrus (Maritza) Then, in 349, he opened war upon Olynthus. Athens sent no adequate forces, in spite of the upbraidings of Demosthenes (*see* his *Olynthiacs*), and in the spring of 347 Olynthus fell Macedonia and the regions adjoining it having now been securely consolidated, Philip celebrated his "Olympian" games at Dium In 347 Philip advanced to the conquest of the eastern districts about the Hebrus, and compelled the submission of the Thracian prince Cersobleptes Meanwhile Athens had made overtures for peace (*see* the *De falsa legatione* of Demosthenes), and when Philip, in 346, again moved south, peace was sworn in Thessaly.

The Phocians, who still dominated Delphi and held Thermopylae, now furnished a pretext to Philip as the champion of Pan-Hellenism and Apollo The Phocian mercenaries at Thermopylae were bought off and Philip crossed into central Greece Here he made Thebes his ally and visited the Phocians with crushing vengeance The Pythian games of 346 were celebrated at the delivered Delphi under Philip's presidency Pan-Hellenic enthusiasts already saw Philip as the destined captain-general of a national crusade against Persia (Isocrates, *Philippus*, about 345) And such a position Philip had determined to secure; the Macedonian agents continued to work throughout the Greek states and in the Peloponnesus Sparta soon found herself isolated Euboea, too, submitted to Macedonian influence.

But more work had to be done in the Balkan highlands In 344, or one of the following years, the Macedonian arms were carried across Epirus to the Adriatic and Thessaly was completely reorganized In 342 Philip led a great expedition north "comparable to nothing in antiquity since Darius' famous march to Scythia" Meanwhile he continued to foster diplomatic relations with various Greek states, and, by conciliatory measures, to support the efforts of the pro-Macedonian party in Athens But Demosthenes eventually carried the day, and Philip came more or less openly to blows with Athens over Diopeithes's behaviour in the Chersonese. Athens then supported the revolt of Philip's allies in Propontis, and struck a heavy blow at his prestige when his sieges of Perinthus and Byzantium failed in 339 But before marching south he led another expedition across the Balkans into the country now called Bulgaria, and returned to Pella with much spoil but severely wounded in the thigh.

In 338 he once more crossed into central Greece The pretext was the contumacy shown by the Locrian town Amphissa to the rulings of the Amphictyonic council Philip's fortification of Elateia filled Athens with alarm Thebes was induced to join Athens, so were some of the minor Peloponnesian states, and the allies took the field against Philip This opposition was crushed by the epoch-making battle of Chaeroneia, which left Greece at Philip's feet. Thebes was occupied by a Macedonian garrison. Athens, which had expected a fight to the death, was treated generously. In the following year (337) Philip was in the Peloponnesus and held a congress of the Greek states at the isthmus (from which, however, Sparta held sullenly aloof) The states attending were organized into an Hellenic league, with a constituent council and a supreme judicial court (the Amphictyonic council), acknowledging the military command of Philip and sending contingents for the expedition against Persia that was next in his plans Philip returned to Macedonia to complete his preparations, an advance force was sent into Asia in the spring of 336. Philip was murdered that year during the marriage festival of his daughter at Aegae, the old capital of Macedonia He left, however, in the Macedonian army a splendid instrument which enabled his son within ten years to change the face of the world

See the authorities under GREECE: *History*. A vivid and masterly sketch of Philip's personality and work is given in D. G Hogarth's

Philip and Alexander (1897). For economic policy, A. B. West in *Numism. Chron.* (1923) 169.

PHILIP III. [ARRHIDAEUS], king of Macedonia, was the feeble-minded son of Philip II. of Macedonia by a Thessalian wife. He was chosen by the Macedonian army at Babylon in 323 to be nominal king conjointly with the infant Alexander, and was killed in Macedonia by order of Olympias (317). (*See* MACEDONIAN EMPIRE.)

PHILIP IV., king of Macedonia, was the son of Cassander, king of Macedonia; he reigned only one year (296–297).

PHILIP V., king of Macedonia, son of Demetrius II. and Chryseïs, was an infant at his father's death in 230–229. His cousin, Antigonus Doson, administered the kingdom as regent till his death in 221–220, when Philip was eighteen years old. Philip now ascended the throne and reigned till 179. His reign was occupied in the vain struggle to maintain the old Macedonian supremacy in the Balkan Peninsula, which became hopeless after the intervention of Rome and the decisive battle of Cynoscephalae (197). *See* ROME: *History.* (E. R. B.)

PHILIP I., the Handsome (1478–1506), king of Spain, son of the emperor Maximilian I., was born at Bruges on July 22, 1478. In 1482 he succeeded to the Burgundian possessions of his mother, Mary, daughter of Charles the Bold. In 1496 he married Joanna, daughter of Ferdinand and Isabella. He died suddenly at Burgos on Sept. 25, 1506.

PHILIP II. (1527–1598), king of Spain, son of the emperor Charles V. and Isabella of Portugal, born at Valladolid on May 21, 1527. Philip was educated in Spain. The emperor, as he moved from one part of his wide dominions to another and in the camps of his armies, watched his heir's education from afar. The trend of his letters was to impress on the boy a profound sense of the high destinies to which he was born, the wisdom of distrusting counsellors, and the necessity for keeping his nobles apart from all share in the conduct of the internal government of his kingdom. Philip grew up grave, self-possessed and distrustful. He was beloved by his Spanish subjects, but utterly without the power of attracting men of other races. Though accused of extreme licentiousness, Philip was probably less immoral than most kings of his time, and he was rigidly abstemious. His power of work was unbounded, and he had an absolute love of reading, annotating, and drafting dispatches. Unhappily for Spain, Charles decided to transmit the Netherlands to his son. In 1543 Philip had been married to his cousin Mary of Portugal, who bore him a son, the unhappy Don Carlos, and who died in 1545. In 1554, Charles summoned Philip to Flanders and arranged the marriage with Mary, Queen of England, in order to form a union of Spain, the Netherlands and England against France. The marriage proved barren. The abdication of his father (Jan. 16, 1556) constituted Philip sovereign of Spain with its American possessions, of the Aragonese inheritance in Italy, Naples and Sicily, of the Burgundian inheritance—the Netherlands and Franche Comté—and of the duchy of Milan. It was a legacy of immense responsibilities and perils, for France was bound to endeavour to ruin a power which threatened her independence. France was beaten at St. Quentin and Gravelines, and forced to make the Peace of Cateau Cambrésis (April 2, 1559). But the death of Mary of England (Nov. 17, 1558) and the establishment of Elizabeth on the English throne, put on the flank of Philip's scattered dominions another power, forced no less than France by political necessities to be his enemy. His marriage with Elizabeth of Valois (June 22, 1559), and the approach of the wars of religion, gave him a temporary security from France. Nevertheless, when Philip went back to Spain, in August 1559, he was committed to a life-long struggle, in which he could not prove victorious except by the conquest of France and England.

External and internal influences alike drove Philip into conflict with the Netherlands, France and England. The conflict became one between Protestantism and Roman Catholicism, in which Philip appeared as the champion of the Church. It was a part he rejoiced to play. His persecutions hardened the obstinacy of the Dutch, exasperated the English and provoked a revolt of the Moriscoes. No experience of the failure of his policy could shake his belief in its essential excellence. Philip had a high ideal of his duty as a king, and had no natural preferences for violent courses. His strong measures in Aragon in 1591 were provoked by extreme misconduct on the part of a faction. When he enforced his claim to the crown of Portugal (1579–1581) he preferred to placate his new subjects by guarding their privileges. He even made dangerous political concessions to win over the gentry. In private life he was orderly and affectionate to his family and servants. He was slow to withdraw the confidence he had once given. In the painful episode of the imprisonment and death of Don Carlos, Philip behaved honourably. He died at the Escorial on Sept. 13, 1598.

As an administrator Philip had all the vices of his type, that of the laborious, self-righteous man, who thinks he can supervise everything, is capable of endless toil, and jealous of his authority. He set the example of the unending discussions in committee and boundless minute writing which choked the administration.

PHILIP III. (1578–1621), king of Spain, son of Philip II., and Anne, daughter of Maximilian II., born at Madrid, April 14, 1578. He inherited the beliefs of his father, but no share of his industry. He left the direction of government entirely to his favourite, the duke of Lerma, and, after the latter's overthrow in 1518, to the new favourite, the duke of Uceda, Lerma's son. Philip's own life was passed amid court festivities, on which enormous sums of money were wasted, or in the practice of childish piety. It was said that he was so virtuous as hardly to have committed a venial sin. He died at Madrid, March 31, 1621.

See R. Watson and W. Thompson, *History of Philip III.* (2 vols., 1876, 1808).

PHILIP IV. (1605–1665), king of Spain, eldest son of Philip III. and Margaret, sister of the emperor Ferdinand II., born at Valladolid April 8, 1605. His reign, after a few years of barren successes, was a long story of political and military decay and disaster. A fine horseman, a keen hunter, and a patron of art and letters, he indulged in these pastimes, leaving the government to his favourite Olivares. When, in 1643, the disasters falling on the monarchy led to the dismissal of Olivares, Philip had lost the power to devote himself to hard work. After a brief attempt at directing the administration of the most extensive and the worst organized monarchy in Europe, he returned to his pleasures and was governed by other favourites. His political opinions were those he had inherited from his father and grandfather. He thought it his duty to support the German Habsburgs and the cause of the Roman Catholic Church against the Protestants, to assert his sovereignty over Holland, and to extend the dominions of his house. The utter exhaustion of his people in a hopeless struggle with Holland, France and England was seen by him with sympathy, but he considered it unavoidable. His court was grossly vicious. Philip IV. died on Sept. 17, 1665.

See A. Cánovas del Castilo, *Estudios del reinado de Felipe IV.* (Madrid, 1889), and the introduction by F. Silvela to the *Cartas de Sor Maria de Ágreda y del rey Felipe IV.* (Madrid, 1885–86).

PHILIP V. (1683–1746), king of Spain, founder of the present Bourbon dynasty, was the son of the dauphin Louis and Maria Anna, daughter of Ferdinand Maria, elector of Bavaria. Born at Versailles, Dec. 19, 1683, he was named heir by the will of Charles II. Carefully educated as duke of Anjou by Fénelon, he was all his life strongly adverse to the moral laxity of most of the princes of his time, and greatly under the influence of his two wives, Maria Louisa of Savoy (d. Feb. 1714), whom he married in 1702, and Elizabeth Farnese of Parma, whom he married in Dec. 1714. His strongest passion was to secure his succession to the throne of France, and in this pursuit he indulged in many intrigues against the house of Orleans, even abdicating in 1724. But when his son Louis died a few months later, he resumed the throne.

See Coxe, *Memoirs of the Kings of Spain of the House of Bourbon* (London, 1815).

PHILIP, Landgrave of Hesse (1504–1567), son of the landgrave William II., was born at Marburg on Nov. 13, 1504. He became landgrave on his father's death in 1509, and having been declared of age in 1518, was married in 1523 to Christina, daughter of George, duke of Saxony. In 1522 and also in 1523 he assisted to quell the rising of Franz von Sickingen (*q.v.*), who had raided Hesse five years previously, and in 1525 he took a leading part in crushing the rebellion of the peasants in north Germany, being mainly responsible for their defeat at Frankenhausen. About this time Philip adopted the reformed faith. His plans to protect the reformers rested upon two main principles—unity among the Protestants at home and military aid from abroad. The schemes he put forward as one of the heads of the league of Schmalkalden, aimed primarily at overthrowing the house of Habsburg. Envoys were sent to seek aid from France, England and Denmark; Turkey and Venice were looked to for assistance; the jealousy felt towards the Habsburgs by the Bavarian Wittelsbachs was skilfully fomented. Before the formation of the league of Schmalkalden Philip was intimate with Zwingli. In 1526 he had aided John the Constant, elector of Saxony, to form an alliance of reforming princes; and in 1529 he called together the abortive conference at Marburg, hoping thus to close the breach between Lutherans and Zwinglians. Deceived by the forgeries of Otto von Pack (*q.v.*), he believed in the existence of a conspiracy to crush the reformers, and was only restrained from attacking his enemies, in 1528, by the influence of John of Saxony and Luther. In 1529 Philip signed the "protest" presented to the diet at Spires, being thus one of the original "Protestants"; in 1530 he subscribed the Augsburg confession, and helped to form the league of Schmalkalden.

He next restored Ulrich, duke of Württemberg (*q.v.*) to his duchy. Württemberg had passed into the possession of the Habsburgs, and after Philip's brief and victorious campaign in 1534 it was said that the landgrave had done more for Protestantism by this enterprise than a thousand of Luther's books would do. The Concord of Wittenberg, made in 1536, was preparatory to a general attack on the Habsburgs, but war was prevented by the illness of the landgrave and other circumstances. At this point he took a fatal step. His union with Christina was unhappy, and, having fallen in love with Margaret von der Saal (d. 1566), he obtained an opinion from Protestant theologians that bigamy was not forbidden by Holy Writ. Luther and Melancthon at length consented to the marriage, but stipulated that it should be kept secret, and it was celebrated in March 1540. The marriage became known, and Philip's friends deserted him. He objected to Luther's counsel to deny the existence of a second marriage. But the general hostility compelled him to come to terms, in 1541, with Charles V. at Regensburg; he undertook to break off relations with France and England and loyally to support the emperor.

From 1526 onwards Philip had been forwarding the progress of the Reformation in Hesse. Catholic worship was suppressed, and the secularized church revenues supplied an endowment of the new university of Marburg. Peace between the emperor and the landgrave was soon broken. In 1542 Philip persuaded the league of Schmalkalden to attack Henry II., duke of Brunswick-Wolfenbüttel, ostensibly in the interests of the Protestant towns of Brunswick and Goslar. The duchy was quickly overrun, and Henry—a Catholic prince—driven out; but the good understanding between the emperor and the landgrave was destroyed, and the relations between Protestants and Catholics became worse than before. Nor was the fissure in the Protestant ranks closed, and Charles took advantage of this disunion to conquer Gelderland and to mature his preparations for overthrowing the league of Schmalkalden. Unlike John Frederick of Saxony, Philip divined, or partly divined, the emperor's intentions, and urged repeatedly that the forces of the league should be put in order. This advice passed unheeded, and when Charles suddenly showed his hand, and in July 1546 issued the imperial ban against the landgrave and the elector, it was seen that the two princes were almost isolated. Fighting began along the upper Danube, and when indecision and want of funds had ruined the league's chances of success, Philip returned to Hesse and sought help from foreign powers; while in defeat the landgrave was induced to surrender to Charles in June by his son-in-law, Maurice, now elector of Saxony, and Joachim II., elector of Brandenburg, who promised Philip that he should be pardoned, and were greatly incensed when the emperor refused to assent to this condition. Philip was sentenced to detention for 15 years, but he was released in 1552, and after the Peace of Passau in this year he returned to Hesse. The landgrave continued the work of reforming and organizing the Church in Hesse. In 1562 he aided the Huguenots with troops, and he was frequently in communication with the insurgents in the Netherlands; but his efforts to form a union of the Protestants were fruitless. Philip, who is sometimes called the *Magnanimous*, died at Cassel on March 31, 1567.

Rockwell, *Die Doppelehe des Landgrafen Philipp von Hessen* (Marburg, 1904); K. Varrentrapp, *Landgraf Philipp von Hessen und die Universität Marburg* (Cassel, 1904); and *Philipp der Grossmütige, Beiträge zur Geschichte seines Lebens und seiner Zeit*, published by the *Historischer Verein für das Grossherzogtum Hessen* (Marburg, 1904).

PHILIP, King (*c.* 1639–1676), chief sachem of the Wampanoag Indians in America, and the son of Massasoit (d. 1662). To Massasoit's two sons, Wamsutta and Metacomet, the English gave the names respectively of Alexander and Philip. Alexander succeeded his father as sachem, and in the same year, while in Marshfield, whither he had gone to explain certain alleged unfriendly acts toward the English, was taken ill; he died on his way home. Philip, who succeeded Alexander, suspected the English of poisoning his brother. The English had grown stronger and more numerous, and had begun to meddle in the internal affairs of the Indians. In 1671 the Plymouth authorities demanded that the Wampanoags should surrender their arms; Philip consented, but his followers failed to comply, and measures were taken to enforce the promise. Philip thereupon went before the general court, agreed to pay an annual tribute, and not to sell lands or engage in war with other Indians without the consent of the Plymouth government. In 1674, when three Wampanoags were executed at Plymouth for the alleged murder of Sassamon, an Indian convert who had played the part of informer to the English, Philip could no longer hold his followers in check. There were outbreaks in the middle of June 1675, and on June 24, the massacre of whites began.

The colony of Connecticut took quick measures of defence, guarded its frontier, maintained its alliance with the Mohegans, and suffered little injury. Massachusetts and Plymouth were slower in acting and suffered great loss. Rhode Island raised no troops, and suffered severely. Early in the autumn Philip went nearly as far west as Albany in an unsuccessful attempt to get aid from the French and the Mohawks and supplies from the Dutch traders. At Deerfield on Sept. 18, about 60 English were killed and the settlement was abandoned. In the spring of 1676 it became evident that the Indian power was waning. The warriors had been unable to plant their crops; they were weaker numerically and more poorly armed than the English, and the latter had also made an alliance with the friendly Naticks and the Niantics. On Aug. 1, 1676 Philip's wife and nine-year old son were captured, and on Aug. 11, an Indian traitor guided the English to the sachem's hiding place in a swamp at the foot of Mount Hope (in what is now the township of Bristol, R.I.) where early the next morning he was surprised, and while trying to escape was killed by an Indian. The head of Philip was sent to Plymouth and set on a pole in a public place, where it remained for a quarter of a century. The struggle was now over in southern New England, but it continued along the north-eastern frontier till the spring of 1678.

See George M. Bodges, *Soldiers in King Philip's War* (Leominster, Mass., 1896); John Gorham Palfrey, *History of New England*, vol. iii. (Boston, 1864); and especially George W. Ellis and John E. Morris, *King Philip's War* (1906). *See* also *Entertaining Passages Relating to King Philip's War* (Boston, 1716; new ed. with notes by H. M. Dexter, Boston, 1865), the account by Col. Benjamin Church (1639–1718).

PHILIP, JOHN (1775–1851), British missionary in South

he joined John Campbell in his second journey to South Africa to inspect the stations of the London Missionary Society, and in 1822 the Society appointed him superintendent of their South African stations. His anger was aroused by the barbarities inflicted upon the Hottentots and Kaffirs (by a minority of the colonists), and he set himself to remedy their grievances. His influence was seen in the ordinance of 1828 granting all free coloured persons at the Cape every right to which any other British subjects were entitled. During 1826–1828 he was in England, and in the last-named year he published *Researches in South Africa.*

One of Philip's ideals was the curbing of colonial "aggression" by the creation of a belt of native states around Cape Colony. In Sir Benjamin D'Urban, Philip found a governor anxious to promote the interests of the natives. When, however, at the close of the Kaffir War of 1834–35, D'Urban annexed the country up to the Kei River, Philip's hostility was aroused. He came to England in 1836, and agitated against the Cape government. D'Urban was dismissed, and Philip returned to the Cape as unofficial adviser to the government on all matters affecting the natives. He died on Aug. 27, 1851.

See South Africa: *History;* G. M'C. Theal's *History of South Africa since 1795* (London, ed. 1908); *Missionary Magazine* (1836–51); R. Wardlaw's *Funeral Sermon,* 1852.

PHILIPPA OF HAINAUT (*c.* 1314–1369), queen of the English king Edward III., was the daughter of William the Good, count of Holland and Hainaut, and his wife Jeanne de Valois, granddaughter of Philip III. of France. By a special dispensation of the pope, Philippa was married to her cousin Edward III. by proxy at Valenciennes in October 1327, and landed in England in December. She joined Edward at York, where she was remarried on Jan. 30, 1328. Her marriage dower had been seized by the queen dowager Isabella to pay a body of Hainauters, with whose help she had compassed her husband's deposition. The alliance ensured for Edward in his French wars the support of Philippa's influential kindred; and before starting on his French campaign he secured troops from William the Good, as well as from the count of Gelderland, the count of Julich, and the emperor Louis the Bavarian.

Before 1335 Philippa had established a small colony of Flemish weavers at Norwich, and she showed an active interest in the weaving trade by repeated visits to the town. She also encouraged coal-mining on her estates in Tynedale. Her eldest son, Edward the Black Prince, was born in 1330, and she subsequently bore six sons and five daughters. In November 1342 she became guardian of John of Gaunt and her younger children, with their lands. The anecdotes of her piety and generosity prove her popularity. On a famous occasion her prayers saved the citizens of Calais from Edward's vengeance. There is a generally accepted story, based on the chronicles of Jehan le Bel and Froissart, that she summoned the English forces to meet the Scottish invasion of 1346, and harangued the troops before the battle of Neville's Cross.

Philippa was the patron and friend of Froissart, who was her secretary from 1361 to 1366. Queen's College, Oxford, was not, as is stated in Skelton's version of her epitaph, founded by her, but by her chaplain, Robert of Eglesfield. Her chief benefactions were made to the hospital of St. Katharine's by the Tower, London. She died on Aug. 15, 1369.

See Agnes Strickland, *Lives of the Queens of England,* vol. i. In addition to the account given in his *Chroniques,* Froissart wrote a formal eulogy of her, which has been lost.

PHILIPPEVILLE, a seaport of Algeria, chief town of an arrondissement in the department of Constantine, and 54 m. N. by E. of that city, on the Bay of Stora, in 36° 53′ N. 6° 54′ E. The population is 29,242, of whom 19,288 are Europeans (16,461 French). It is connected by railway with Constantine, Batna and Biskra. The town derives its importance from being the port of Constantine. From Cape Skikda, on the east, a mole or breakwater projects 4,592 ft. to the west-north-west, while from Château Vert, on the west, another mole runs out 1,312 ft. to the north, leaving an entrance to the port about 656 ft. wide. The protected area comprises an outer and an inner basin. The depth of water at the entrance is about 33 ft., by the quays about 20 ft

Philippeville occupies the site of successive Phoenician anc Roman cities. By the Romans it was named Rusicada. Som parts of the Roman theatre remain. The modern town was founde by marshal Valée in 1838.

PHILIPPI (Turk. *Filibejik*), a city of ancient Macedonia, o a steep hill near the river Gangites (mod. *Angista*), overlookin an extensive coastal plain on the highway between Neapolis (Ka valla) and Thessalonica. Originally called Crenides (Fountains) it was fortified by Philip II. of Macedon, to command the neigh bouring gold mines. In 42 B.C., after the defeat of Brutus anc Cassius here by Octavius and Antony, it became a Roman colony *Colonia Julia Philippensis,* probably increased after the battle o Actium (*Col. Aug. Julia Phil.*), with the Jus Italicum, and th rank of a "first city." It was twice visited by St. Paul, whos Epistle to the Philippians was addressed to converts here. Th site, now uninhabited, is marked by ruins of an amphitheatre anc a great temple with inscriptions. To the east is the huge monu ment of C. Vibius, known to the Turks as Dikelitashlar and t the Greeks as the Manger of Bucephalus.

See Heuzey and Daumet, *Mission arch. en Macédoine,* Paris (1865) and other authorities in bibliography of Macedonia; *Corp. Insc Lat.* iii. 1.; S. Casson, *Macedonia, Thrace and Illyria* (1926).

PHILIPPIANS, EPISTLE TO THE, a book of the Nev Testament. Though Philippi was the first place in Europe wher St. Paul preached the gospel, the letter to the local church was on of the last he wrote. Ever since he founded the church, he kep in touch with it (iv. 15f); indeed he had accepted a gift of mone from it. But the present letter is an answer to one written b the Philippian Christians, who had enquired anxiously about hi health and prospects, assuring him of their prayers, and wonder ing when he would be able to revisit them (i. 25f). Epaphroditus who had brought the money, had fallen ill, and the apostle appar ently sends him back reluctantly, perhaps with the present lette It is a friendly missive, which falls into two parts. The firs begins by relieving their anxiety about himself, assures them tha he hopes to return before very long, and warns them, in the mean time, to preserve their unity (i.–ii.). At this point there is sudden change in tone. The letter swerves into a passionat denunciation of some errorists or agitators (iii. 1f), after whic the writer resumes (iv. 1–7) his counsels to the community. Th closing appeal (iv. 8f) is for harmony.

Modern criticism of the epistle is no longer concerned wit supposed traces of gnosticism in ii. 6f. The two engrossing ques tions are (*a*) the place from which the letter was written, and (*b* whether or not it is a literary unity.

The former problem is raised by those who point out that th Greek term "praetorium" ("palace" in the English version of i 13) does not necessarily mean the Roman barracks of the prae torian guard at Rome, but might conceivably, for example, refe to the palace of Herod at Caesarea (Acts xxiii. 35) or to judicia authorities at a centre like Ephesus, where we know Timotheu was living (Acts xix. 22), and where the apostle was once im prisoned. The data indicating Rome as the place of compositio cannot be hastily set aside, *i.e.,* the considerations which involv the latter part of the two years confinement at Rome (Acts xxviii 30) as the period when the letter was written.

The second problem starts from the abrupt change in iii. 2. I is thought by some (*e.g.,* by B. W. Bacon, *The Story of St. Paul* pp. 367f) that iii. 2f represents an earlier letter, written in repl to the gift of money, and subsequently added to the later i. i.- iii. 1, as 2 Corinthians x.–xiii. has been added to an epistle whic chronologically it preceded. The partition theories, of whic this is the simplest form, imply that two letters have been muti lated and transposed; otherwise, the hiatus at iii. 2 is inexplicabl But the writer may have been interrupted at iii. 1, or somethin may have occurred which moved him to turn aside sharply In iv. 4 he echoes the note sounded in iii. 1, and the intervenin outburst may be psychologically explained without recourse t any theory of transposition.

He associates Timotheus with him in the address (i.1), owin to his local ties with Philippi (ii. 22 and Acts xvi. 3f), but th

apostle writes in the first person throughout, even in iv. 21; indeed he speaks of his companions as distinct from himself, and iii. 17 is no real exception to this. The letter is an affectionate personal message from St. Paul in the evening of his life to a church with which his relations had been exceptionally friendly. Their troubles were not connected with doctrine; the great passage in ii. 5f is introduced as a motive to humility, not as specific instruction on the person of Christ. These Macedonian Christians had a naturally affectionate temperament, which affected their religion; the apostle's chief prayer for them is that their emotional warmth may ripen into insight and understanding (i. 9f), and his concern for them is solely for their Christian principles of conduct.

The earliest definite traces of the letter in second century literature occur in Polycarp, who had some close interest in the church of Philippi. It passed at once into the early canons of Scripture, and soon was quoted by church fathers like Irenaeus, Clement of Alexandria and Tertullian.

Bibliography.—In English the older commentaries by Ellicott (5th edition, 1888) and Lightfoot (6th edition, 1891) may be supplemented by H. A. A. Kennedy's in the *Expositor's Greek Testament* (1903), M. R. Vincent's in *The International Critical Commentary* (1897), and a commentary on the English text by M. Jones (*Westminster Commentaries*, 1918). The latest German editions are by Lohmeyer (Gottingen, 1928), P. Ewald in Zahn's *Commentar* (1923), and M. Dibelius (in Lietzmann's *Handbuch*, 1913), but A. Klöpper's (1893), Von Soden's (1903), and R. A. Lipsius's (*Handcommentar*, 1892) are by no means superseded. General studies of the epistle will be found in R. R. Smith's *The Epistle of St. Paul's First Trial* (1899), in Sir W. M. Ramsay's *St. Paul the Traveller* (chapters x. and xv.), and in Weizsäcker's *Apostolic Age* (vol. i. pp. 218f, 279f). Weizsäcker dealt the deathblow to the older view that the epistle was non-Pauline, the last traces of which are to be found in van Manen's article in the *Encyclopaedia Biblica* (3703f). (J. Mof.)

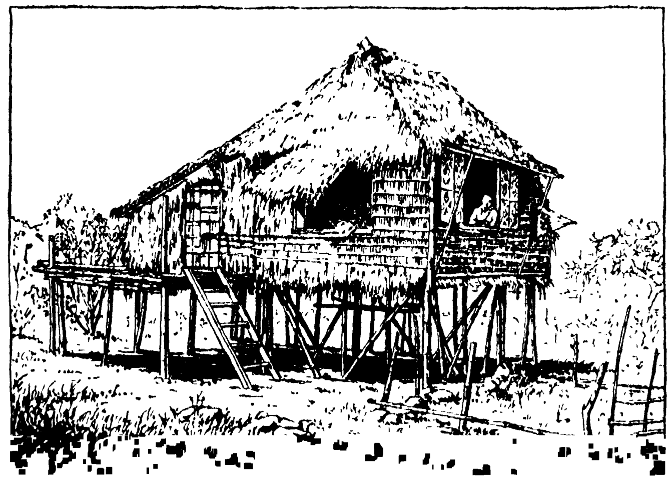
PHILIPPICS. Properly, certain speeches delivered by Demosthenes against Philip II. of Macedon; hence Cicero's speeches against Antony (Cicero *ad Brutum*, II. 3, 4; 4, 2); hence, in modern use, any impassioned invective.

PHILIPPICUS, East Roman emperor (711–713), became distinguished as a soldier under Justinian II. His proper name, which indicates his Armenian origin, was Bardanes. He made some pretensions to the throne on the outbreak of the first rebellion against Justinian; these led to his banishment, by order of Justinian, to Cherson. Here Bardanes successfully incited the inhabitants to revolt, and on the assassination of Justinian assumed the purple. Among his first acts was the summoning of a *conciliabulum* of Eastern bishops, which momentarily restored monotheletism. His domains were attacked at once by Terbelis king of the Bulgarians in Europe, and the Saracens in Asia. The reign of Philippicus was ended by a military conspiracy.

See Gibbon, *Decline and Fall of the Roman Empire* (ed. Bury, 1911), v. 195–6.

PHILIPPINE ISLANDS, an archipelago, named after Philip II. of Spain, of approximately 7,083 islands, belonging to the United States, about 500 m. off the S.E. coast of Asia, between lat. 4° 41′ and 21° 10′ N., and long. 116° 40′ and 126° 34′ E. To the west and north is the stormy China sea, east the Pacific ocean, and south the Sea of Celebes and the coastal waters of Borneo. They extend north and south about 1,152 m. and east and west about 688 m., their shape, if bounded by straight lines, being about that of an isosceles triangle, and their area 114,400 sq.m., or about 7,000 sq.m. less than that of Great Britain. The northernmost island, Y'Ami, is 65 m. from Formosa, while the southernmost, Saluag, is 30 m. E. of Borneo. Of the islands only 462 have an area of 1 sq.m. or over and only 2,441 have names. Eleven islands have an area of over 1,000 sq.m. each, namely, Luzon, the most northerly of the large islands, 40,814 sq.m.; Mindanao, the most southerly, 36,906 sq.m.; Samar, 5,124 sq.m.; Negros, 4,983 sq.m.; Palawan, 4,500 sq.m.; Panay, 4,448 sq.m.; Mindoro, 3,794 sq.m.; Leyte, 2,799 sq.m.; Cebu, 1,695 sq.m.; Bohol, 1,534 sq.m.; and Masbate, 1,255 square miles. In addition to the large islands and those with distinct names are various groups, among which may be noted the Babuyanes and Batanes, north of Luzon; the Bisayas (or Visayas) between Luzon and Mindanao; the Cagayan and the Calamian groups, respectively islands, the chief of which is Jolo.

Physical Features.—The irregular configuration of the archipelago, the coastline of over 12,500 m., the great extent of mountainous country with the mountains lying close to the sea in many places, the narrow and interrupted coastal plains, the generally northward trend of the river systems and the lakes, comprise the salient physical features of the Philippines. The islands are



BY COURTESY OF THE CANADIAN PACIFIC STEAMSHIPS
A PHILIPPINE HUT NEAR GUADALUPE, MANILA, BUILT ON STILTS TO AVOID FLOODING FROM HEAVY RAINS

partly of volcanic and coral or other formation. The mountain ranges for the most part run in the general direction of the main axes of the islands. The Cordillera Central of Luzon, running north to the Pacific ocean from the northern boundary of the central plain, is the most prominent chain. It consists of two, and, in places, of three, parallel ranges, each of which averages 5,900 ft. in height. The narrow Ilocos or Malaya Range, lying close along the narrow west coast, rises in places to over 5,000 ft., and the Sierra Madre, fringing the north-east coast, to over 5,000 ft., and is seldom less than 3,500 feet. It is largely volcanic. This range and the Cordillera Central coalesce in Nueva Vizcaya forming the Caraballo mountains. North of the latter and between the two ranges is the fertile Cagayan valley, about 50 m. wide. In the south-western part of northern Luzon are the rugged Zambales mountains, which consist of more or less isolated old volcanic stocks. The central plain of northern Luzon is about 150 by 50 m. and only about 100 ft. above sea-level except near its centre. The greater part of Southern Luzon is occupied by isolated volcanoes and irregular masses of hills and mountains. The highest peak is Mayon (7,900 ft.) near Legázpi in Albay Province. Through Palawan (about 15 m. wide) extends a range with an average height of 4,000 to 5,000 feet. Each of the Bisayan islands, except Samar and Bohol, is traversed longitudinally by a single range with occasional spurs. Several peaks in Panay reach an altitude of 6,000 ft. or over. In Negros is Mt. Canlaon, a volcano of 7,800 ft., and other peaks reach an altitude of over 6,000 feet. There are several important ranges in Mindanao, the Diuata Range along the eastern coast being the most prominent.

West of this lies the fertile Agusan valley, 40 or 50 m. wide. Farther west and south-west is the valley of the Río Grande de Mindanao, the largest river in the island, and below the lower course of this river and the southern coast lies a range trending north-west and south-east. On the southern border of the basin of the above river is Mt. Apo (9,610 ft.), the highest peak in the Philippines. About Lake Lanao are a number of volcanic peaks. A low cordillera extends into Zamboanga Province. Many of the mountains are covered with dense forests in which are many valuable hardwood timbers. In northern Luzon, the principal mountain tree is the pine. In many places where the forests have been burned away, their place has been taken by cogón or other coarse grasses. The plains lying amid the mountains, *e.g.*, the central plain of Luzon, the Bikol plain of south-eastern Luzon, the Cagayan plain of northern Luzon, the central plain of Panay

densest populations of the islands except in Cebu, where the people live mostly on the coastal plain, as the interior is high and rugged. The most important rivers are the Cagayan, Agno, Pampanga, Pasig and Bikol in Luzon; and the Río Grande de Mindanao and Agusan in Mindanao. The Cagayan flowing northward through northern Luzon, and draining about one-fourth of the island, is the largest river. This river and the Río Grande de Mindanao and the Agusan are each over 200 m. long. The Pasig is a most important river commercially. The largest lake in the archipelago is Laguna (Lake) de Bay, located very near Manila.

Geology.—Mountain building is still in progress and evidence of the recent vertical movement of various portions of mountain mass can be measured. The archipelago is the crumpled edge of the Asiatic continental platform. However, the structure is a complex one, for besides faulting and folding, volcanic actions of diverse kinds have taken place. Prior to the Tertiary period there seems to have been a period of intense deformation, when some of the schists were formed. Toward the end of the Miocene period, the Vigo and Batan formations were generally folded, in some places being intensively crumpled and faulted. Another less pronounced period of folding occurred in the Pliocene or early Pleistocene period. The islands were subjected to a great uplift during the Pliocene, Pleistocene and recent periods. A striking similarity exists between the formation in the Philippines and the western coast of America. Practically all the rock types are found in the islands, as well as areas of coral limestone.

Volcanoes and Earthquakes.—The volcanoes are the most conspicuous feature of the landscape, but there is less volcanic activity in the whole group than in a single Hawaiian island. However, all gradations of volcanoes can be seen, from the almost perfect cone of Mayon to old, worn down volcanic stocks whose present form gives little indication of their origin. The several distinct volcanic areas are that of south-western Luzon (the provinces of Rizal, Cavite, Laguna, Batangas and a portion of north-western Tayabas); that of south-eastern Luzon; the mountain region in Camarines Norte; Negros; Mindanao; Jolo; and a few others. Seismic disturbances are common.

Climate.—The mean annual temperature is 26·9° C (80·4° F). There are seven months (April to October) with a mean monthly temperature of 26·9° to 28·1° C, and five (November to March) with 25·4° to 26·5° C. May is the warmest and January the coolest month. During the period 1903–18, the highest absolute temperature for Luzon was 42·2° C and the lowest, 12·1° C, and the highest and lowest for the Bisayas and Mindanao, 38·2° C and 13·3° C respectively. The Philippines would have little difference of climate if the rainfall were homogeneous. There are three types of climate The first is characterized by two pronounced seasons, dry (with less than 2 in. of rainfall) in winter and spring and wet in summer and autumn. Cyclonic or summer rainfall prevails. This type occurs in the western part of Luzon, Mindoro, Negros and Palawan, and the western and southern parts of Panay. The second type is characterized by no dry season, has a pronounced maximum of rainfall in winter, and prevails along the eastern part of the archipelago from about the latitude of Manila southward, or in south-eastern Luzon, Samar, eastern Leyte and in Surigao Province, Mindanao. The third or intermediate type has no very pronounced rain period and a short dry period of only one to three months. The average annual rainfall for the archipelago (whose annual mean varies between 181 and 38·9 in.) is about 93·1 inches. The subprovince of Benguet averages the heaviest precipitation—over 157 in. in 1911. The average for the whole archipelago shows 159 rainy days. The floods are usually caused by typhoons. Severe droughts occur at times especially in the west—two remarkable drought periods being those of 1911–12 and 1914–15. In terms of the rainfall there are said to be three seasons: the dry (January to May); the rainy (June to October) and the relatively dry (November to December).

Flora.—About 10 000 species of flowering plants and ferns have been found. The flora is essentially Malaysian, but continental (Himalayan) elements occur in the mountains of northern Luzon, while a few Australian types are found at various altitudes. There is a small percentage of endemic genera and a very high percentage of endemic species (about 60%). The dominant forest species are usually endemic. Among the grasses of the grasslands are lalang (cogón), and other coarse grasses. The vegetation of the coastal regions (including the mangrove swamps) is practically identical with that of similar areas throughout the Malay archipelago. Considerably more than half the land

BY COURTESY OF THE U.S. BUREAU OF INSULAR AFFAIRS

A HEMP PLANTATION IN THE PHILIPPINE ISLANDS

area of the islands is covered with forests. There are many valuable hardwoods as well as many of the softer variety. About 1,000 different woods have a commercial value, among which may be noted apitong, camagón, ipil, lauan, mayapis, molave, narra, tangile, tindalo and yacal. Some timber trees attain a huge size which makes them especially adaptable for tables and other large pieces of furniture. There are many useful kinds of palms, including the coco-nut palm, from which the Filipino obtains food, clothing, fibre for export, coco-nut oil, copra, building material and other products. Useful bamboos and rattans abound. About 900 species of orchids occur, some of them very rare. Several hundred fibres are known, among them the abacá, from which manila rope is made. The forests also yield gums including rubber, various fruits, nuts, spices and drugs, oils and other useful substances.

Fauna.—Mammals are scarce, with the exception of shrews, rats, mice and bats. The edentates are represented by the *pangolin* (*Manis javanica*). Red or brown deer (*Rusa*) are found in Basilan, Mindanao, Leyte, Samar and the Calamian islands. The mouse deer or chevrotain (*Tragalus nigricans*) is found in Balabac and Palawan. The timarau (*Bubalus mindorensis*), a small buffalo, is peculiar to Mindanao. Carnivores are represented by mongooses (*Mungos palawanus* and *M. parvus*), the binturong (*Arctictis whitei*), an otter (*Aonyx cinerea*), civet cats (*Viverra* and *Paradoxurus*) and a small wildcat (*Felix minuta*) which is also found in Java. At least 56 species of bats are known, many being peculiar to the Philippines. The flying lemur (*Cynocephalus volans*) and tarsiers (*Tarsius*) range from Basilan to southern Luzon. Large fruit bats live in colonies and are sometimes hunted for their flesh and fur. Only one genus of monkey (*Pithecus*) has been found but it is represented by five species. Five new genera of small mammals (*Celaenomys, Chrotomys, Rhynchomys, Batomys* and *Carpomys*) representing 15 species were discovered some years ago on a small plateau on the top of Mt. Data in northern Luzon, at an altitude of about 3,200 feet. There are about 760 species of birds which show rather strong relationship to those of Borneo. Reptiles and batrachians also abound.

The marine fauna is one of the most abundant known, more than 1,000 species having been found, three-fourths of which at least are used as food. Sharks and rays are caught for their fins, which are prepared for the Chinese market. The fresh-water fish fauna is relatively unimportant. Terrestrial and marine molluscs are very abundant, the Philippines having the richest molluscan fauna of any equal area in the world, and many of the shells are of great beauty. Many of the molluscs are edible and of considerable local importance. Pearl oysters abound and the pearls

of the Sulu archipelago have an international reputation. The shells of *Placuna placenta* are a welcome substitute for window glass. Land molluscs are found in great variety and are remarkable for their beauty. The best sponges of the southern islands are equal to those of the Mediterranean. Coral beds are numerous.

Population.—The population in 1903 was 7,637,426 and in 1918, when the second census was taken, 10,314,310, of whom 9,381,357 were Christians. The computed population in 1928 was about 12,000,000. Excluding Manila (where there were 20,379 to the square mile), the most densely populated province was Ilocos Sur (492 inhabitants to the square mile) and the provinces of Nueva Vizcaya in Luzon and Agusan in Mindanao, the least (each with 10 to the square mile). Cebu (with 855,065 inhabitants) was the most populous province, and was followed by the provinces of Leyte (597,950), Pangasinan (565,922), Iloilo (502,949), Occidental Negros (396,636), Samar (379,575), Bohol (358,387) and Batangas (340,199). Based on the total of 9,492,328 (census of 1918 of regularly organized provinces and subprovinces), races were represented as follows: brown, 9,386,826; yellow 50,826; white, 12,390; American negro, 185; aeta, 7,438; and mestizo, or mixed blood, 34,663. There were 9,428,291 Filipinos, 5,808 Americans from the United States, 4,032 Spaniards, 1,202 British, 288 Germans, 182 French, 125 Swiss, 44,239 Chinese, 8,294 Japanese and 979 others. Literate Filipino citizens of ten years and over numbered 3,759,138; illiterates, 3,242,627. There were 2,601,299 agricultural labourers; professional, 685,507; domestic service, 1,853,804; commercial, 426,547; industrial, 865,698; unknown, 8,295. There were 7,790,937 Catholics; 1,417,448 Aglipayans; 124,575 Protestants; 443,037 Mohammedans; 508,596 Pagans; 24,263 Buddhists; and 5,454 others. The population of the only two incorporated cities, Manila and Baguio, was respectively 285,306 and 5,464. Cebu, with 65,502 inhabitants, Albay, with 52,756, Iloilo, with 49,114 and Lipa, with 46,547 were the largest municipalities of the first class.

There are 43 ethnographic groups. The Filipinos proper (the descendants of the Malays christianized by the Spaniards) are composed of eight peoples. These are the Bisaya, Bisayans or Visayans (about 4,000,000, several dialectal groups, Bisayan islands); the Tagalog (Central Luzon, about 1,800,000); the Iloko (Ilocanos, in Ilocos Norte, Ilocos Sur and neighbouring provinces, about 1,000,000); the Bikol (Albay, Camarines Norte and Camarines Sur, Luzon, about 700,000); the Pangasinan (about 400,000); the Pampangan (Pampanga and Tarlac, about 350,000); Ibanag (Cagayan, about 156,000); and the Sambal (Zambales, about 56,000). These are all Christians, and other Christian groups, in all about 41,000, exist among other peoples. The classified pagan peoples are represented by 18 groups, the unclassified pagans by 12, and the Moros by 7. Of the 43 languages and dialects, those with an extensive printed literature are the Tagalog, Bisaya, Iloko, Bikol, Pampangan and Pangasinan. The non-Christians are divided into pygmies, Indonesians and Malays. The first are the Negritos (small blacks), who probably represent three quite distinct aboriginal races; viz., the true Negrito; a straight-haired dwarf type of strong mongoloid affinities, to whom the name Proto-Malay has been applied; and the Australoid-Ainu, a dwarf hairy man intermediate between the aboriginal Australian and the Ainu of northern Japan. The three types, however, are now thoroughly mixed. The pygmy types are found in the Apayao swamp regions, the Ilokos mountains, the Luzon mountains, the Bisaya islands and Mindanao.

SAVAGE MAN AND WOMAN OF THE PHILIPPINE ISLANDS

The Indonesians were immigrants who appear to have mixed extensively with the pygmy peoples, and others. They practised a crude agriculture, but lived mainly by hunting and fishing. They had two types of houses—one built in trees and the other on the ground. Their early speech is gone, but there are remnants of it in the different Philippine languages. They are found now in northern Luzon, the Bisaya islands, Mindoro, Palawan, east and central Mindanao, the Zamboanga peninsula and the Sulu archipelago. Like the pygmies they live in the thinly populated forest regions. The non-Christian Malays are pagan or Mohammedan. The pagan Malays (Tinggians, Bontok, Igorot and Ifugao) live in the mountainous interior of northern Luzon. Their lands are largely deforested and thickly populated. They practise irrigation by an elaborate and extensive system of channels and ditches, some several miles long. The mountain sides of Ifugao form the most extensive terrace system in the world, and this has existed for centuries. About one-half the Tinggians, who live in Abra Province and near by regions, are Christians and have attained a high culture. The Bontok, whose origin is not known, have mixed quite generally with their neighbours and approach the Igorot and the Ifugao in culture. The Igorot inhabit Benguet, Lepanto and Amburayan. They grow and weave cotton, make baskets and have mined gold and copper for centuries. Their culture has been influenced by contact with the Iloko. The Ifugao are the most numerous of all pagan groups. They inhabit Ifugao, Benguet, Bontok and Nueva Vizcaya. They possess a relatively high culture, which seems to have come from south China. The Ifugao are remarkable for their stone-walled terraces, wooden, pyramidal, rat-proof houses, their clan type of social organization and ancestor worship, and private ownership of real property. These peoples were formerly all head-hunters.

The Moros, representing seven ethnographic groups, live almost exclusively in the Sulu archipelago at the southern end of Palawan, and the Mindanao provinces of Zamboanga, Cotobato and Lanao. Many also live in northern Borneo, and it is not uncommon for them to pass to the Philippines. The great majority are apparently descended from native pagans who were mohammedanized subsequent to the 14th century by outsiders from Sumatra and the Malay peninsula, via Borneo. Their descendants still constitute the ruling class and are the strongest adherents to the Mohammedan faith. The Moros have long been famous for their fine metal work, wood-carving and weaving. Only since 1915 have the Moros surrendered their temporal power.

At the time of the Spanish conquest the ancestors of the present Christian peoples had a fairly well defined social and political organization and possessed written alphabets of Hindu derivation. Where Mohammedanism was already strongly established, as among the Moros, it maintained its hold, but the animistic belief of the others yielded easily to Christianity. The ancestors of the present pagans had comparatively little contact with Christianity during the Spanish régime. As a whole, the people have great self respect and personal dignity, are eager for education, musically inclined, hospitable and impressionable. In social contact they are a charming, idealistic race. Their evolution is probably toward a homogeneous people, but the racial cleavages are very apparent and sometimes stand in the way of united and lasting action. Their political development, which has been manipulated by clever politicians, has outstripped their other attainments.

Agriculture.—The total land area is 74,174,000 ac.; commercial forests, 39,762,370 ac.; non-commercial forests, 7,285,832 ac.; cultivated land 9,281,780 ac.; grass and open land, 13,996,492 ac.; mangrove swamps, 677,170 ac.; and unexplored, 3,070,355 acres. Agriculture is the principal occupation, and the peasants are excellent farmers, notwithstanding their crude methods. The census of 1918 showed 1,995,276 farms, with an aggregate area of 11,409,307 ac., of which 6,040,445 ac. were under cultivation. Of these farms, 1,520,026 were privately owned. Americans owned 2,678 farms (35,552 ac., of which 16,605 were cultivated); and Filipinos 1,946,580 farms (11,202,162 ac., 5,962,755 cultivated). There were 741,437 farms of over ·87 ac. each, but less than 2·5 ac., and 3,433 of 250 ac. or over. (These figures do not include the lands cultivated by the pagan or Moro peoples.) The farms were mainly in the provinces of Pangasinan, Cebu,

Ilocos Norte, Ilocos Sur, Bohol, Union, Leyte, Iloilo, Batanes, Camarines Norte, Camarines Sur, Samar, Laguna and Cagayan. The Indonesian peoples of northern Luzon are careful agriculturists, especially the Ifugao, whose rice terraces are among the marvels of the orient. In all parts of the archipelago, one still sees the old destructive caingin method of clearing by which forests are burned and the soil denuded of humus.

The amounts and approximate values of the crops in 1926 were as follows: rice, 2,264,772 short tons, value, $102,025,500; corn, 375,400 short tons, $18,685,000; sugar and sugar products (sugar, 573,650 short tons, raw sugar, 36,120 short tons, basi, 1,136,010 gal., and molasses, 1,568,563 gal.), $40,568,500; coco-nuts, 1,627,379,000 (trees in bearing, 54,650,000; producing 26,161,278 gal. of tuba or sap, 404,670 short tons of copra, 472,-429 gal. of coco-nut oil; desiccated coco-nut and home consumption, 148,759,000 coco-nuts), $40,684,500; abacá 212,520 short tons, $33,248,500; tobacco, 748,920,000 lb., $18,685,000. Rice is the largest crop and is entirely consumed in the archipelago, but additional supplies have always been imported. In 1926, imports of rice cost $4,500,000 and in 1927 only $1,000,000. At the same time there has been an increase in the import of wheat flour. Much land is still available for rice. Corn is grown especially in Cebu. The first sugar was exported to the United States in 1795 (132 long tons). Until the establishment of the first sugar factory, or *central*, in 1910, the sugar made was practically all muscovado, but in 1926 the 34 centrals were making centrifugal sugar and had a daily capacity of 529,993 metric tons of cane. Cane is grown principally in Occidental Negroes, Pampanga, Batangas, Mindoro, Iloilo, Ilocos Sur, Pangasinan and Tarlac. Albay is the best cane producing region. Other fibres produced are maguey, sisal, cotton, kapok, and piña. The Philippines rank after the Dutch East Indies and the Malay Federated States in the production of coco-nuts. The best grades of tobacco come from Cagayan, Isabela and Nueva Vizcaya, which furnish the exports. Among fruits are various citrus fruits, mangoes, bananas (many varieties), nancas, chicos, lanzones, watermelons and guavas. The peanut crop is of increasing importance. Sweet-potatoes are raised in all parts for local consumption. Bamboos are gathered for building purposes, and bamboo buds and shoots are eaten as a salad. The areca nut is an important product, and wrapped in lime and betel leaf constitutes the betel chewed throughout Malaysia.

Timber covers an area about the size of Nebraska. Over 99% of it belongs to the Government and is administered by the bureau of forestry. The volume of the timber is about 192,000,-000,000 bd.ft.; the output for 1926 was 1,140,664 cubic metres. A number of sawmills are in operation in various districts, some of them using water-power. The public forests are developed under a licence system. Among important forest products are nipa, alcohol, rattan, copal, dye-woods and bark, gutta percha and rubber, paper pulp, fibres, nuts, wax, honey and soap bark.

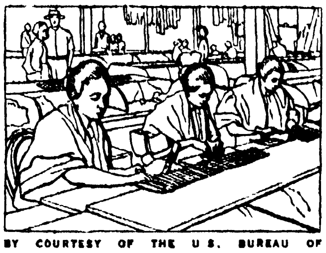
PHILIPPINE NATIVES OPENING COCO-NUTS FOR COPRA

The domestic animals include bovine cattle, carabao, horses and mules, hogs, goats and sheep. The rinderpest campaign has had good results but more carabao are needed for the farm work.

Mineral Resources.—Among non-metallic substances are various abrasives (including corundum), alum, bituminous rock (asphalt), cement, clay, coal, gypsum, lime, mica and talc, mineral waters, ochre, salt, sand and gravel, stone and sulphur. Some agate, opal and amethyst have been found and there are rather extensive but little worked guano and phosphate deposits. Of the above substances, coal is the most important. It is found principally on Batan island (Cebu), Cebu island itself, Polillo, Mindanao, Mindoro and Masbate. Very little mining was done until after 1890. Since U.S. occupation, the deposits on Batan have been worked both by private enterprise and by the Government (to which the deposits now belong). The deposit in one field in Cebu is said to amount to at least 7,000,000 tons. Coal occurs in three states: semi-anthracite, sub-bituminous and lignite. Petroleum exists in seepages. The first mention of gas or petroleum was in 1890. Among the many mineral waters some are hot or with marked medicinal properties. Sulphur is found in or near the cone of volcanoes. Metallic minerals include chromite, copper, gold, iron, manganese, lead and zinc, molybdenite, silver and wolframite. There has been practically no production of copper since U.S. occupation. The principal deposit is in the Mankayan properties in Luzon. Gold can be washed out of most of the rivers. Notable deposits are found in the Paracale region in Camarines Norte, near Baguio in Benguet, in Masbate, Mindanao and other regions. Benguet deposits have been worked for centuries. The total production of gold in 1925 was 2,928,003 fine grams, valued at $1,945,989.



BY COURTESY OF THE U.S. BUREAU OF INSULAR AFFAIRS

WOMEN MAKING CIGARS IN MANILA

Lateritic iron deposits in Mindanao are reported to run to 500,000,000 tons. This field is now a Government reservation. The most notable iron deposit (1,200,000 tons) is that of the Angat (Bulacan), which is of high grade hematite. In 1919, about 20,000 tons were mined, but in 1923 this had fallen to 269 tons, and in 1925 to 398 tons valued at $31,295—all coming from Angat. The decline was due to a wharfage duty of two pesos ($1) per ton. The Angat mines belong to and are worked by Filipinos: almost all the output is made into plough points which are esteemed more highly than imported ones. Unexploited manganese occurs in Ilocos Norte, Pangasinan, Bulacan, Tarlac and Masbate. Lead and zinc occur in many places, always associated, and silver is usually found with them. Deposits in Cebu and Masbate are being exploited. There has been no production of molybdenite, but it occurs in Batangas and one or two other localities. Platinum occurs in very small quantities in Luzon and Mindanao. Some native silver is found in Baguio, but usually in conjunction with lead and zinc. Production in 1925 was 2,132,521 fine grams. Wolframite is reported from Antique, Panay.

Manufacturing in 1918 was conducted in 8,354 establishments. Of these 2,663 were sugar mills (capital about $31,204,-000; output $41,073,000) and 452 were rice mills (capital, about $1,698,000; output $21,731,500). In 1918, manufactures for export included alcoholic liquors, beer, candles, tree oil, coco-nut oil, coffee, copra and coco-nuts, embroideries, fruits and nuts, gum copal, hats, maguey, ilang-ilang oil, indigo, knotted hemp, lumber, abacá, metals, old copper, pearl buttons, pearls, raw rubber, rope, dye-wood, shark fins, shells, sugar, trepang or balate and tobacco—the total value approximating $135,194,500.

Household industries are actively fostered by the Government. In 1913, 31 different classes of industry had 500 or more establishments, chief among which (in the order named) were: fibre textile industries (25,701 establishments); spinning (12,080); hats (9,975); spirits (8,315), cotton textiles (8,046); copra drying (5,434); buri mats (5,207); tailoring (4,075); abacá stripping (3,470); cotton burlap (3,212); and fish drying and smoking (2,107).

Fishing and Fisheries.—Of about 1,600 different species of fish only about 100 kinds are marketed, although the majority of them are edible. The most common are groupers, mackerels, snappers, sea basses, porgies, pampanos, mullets, anchovies, barracudas, tunas, bonitos and eels. Fish ponds are of recent development; the first was established in 1863 in Malabon near Manila. Now they exist everywhere about Manila bay and the Gulf of Lingayen. Fish exports amounted to 873,180 lb. in 1926 ($116,-750), consisting principally of beche-de-mer and shark fins. Other marine products include coral, pearls, shells and sponges; but comparatively few pearls are exported. In 1926, exported shells were valued at over $500,000. Among the shells and shell products are mother of pearl, trocha, tortoise, green snail shells, shell used for windows and pearl buttons.

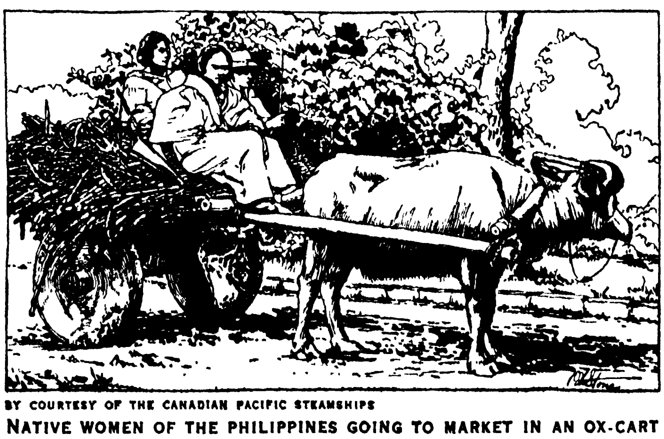
Communications and Transportation.—Since U.S. occupa-

tion, good roads and bridges have been built and maintained everywhere. In 1926 there were 3,630·8 m. of first class roads. In 1926, there were 791 m. of public railways (659 m., narrow gauge in Luzon, 72 m. in Panay, and 60 m. in Cebu).

The Manila Electric Co. operates about 55·9 m. of street railways in and near Manila. At the close of 1927 there were 579 mail routes, 943 post offices, 557 money order offices, 916 postal savings banks, 444 telegraph stations (including radio stations), and 61 postal stations. There is free mail delivery. The average time for passenger vessels from Manila to Seattle is 24 days; to San Francisco, 28 days; to New York via the Panama or Suez Canal, 45 days; to London, via the Suez Canal, 35 days. The Radio Corporation of the Philippines inaugurated trans-Pacific radio service to San Francisco and direct communication with nearby oriental countries and with Berlin in 1926. Radio service with British North Borneo had been inaugurated on April 9, 1920. Cable service is furnished by the Eastern Extension Australia and China Telegraph Co. Ltd., and the Commercial Pacific Cable Company. There are docks at Cebu, Iloilo, Jolo and Zamboanga where ships can moor, but Manila is the only port with adequate facilities. There are in all about 200 ports of call for inter-island shipping.

Cultural and Social Life.—During the early years of the U.S. occupation, Gregorio Aglipay, a former Roman Catholic secular priest, together with a layman, Isabelo de los Reyes, established a new cult known as the Aglipayan Church. The Jesuits were expelled in 1769 and did not return until 1859, when they entered as a missionary and teaching organization. They founded the Manila Ateneo, which was the best institution of high school rank established during the Spanish régime. In the 19th century the Capuchins and the Benedictines established themselves in Manila. Since 1898 a Belgian missionary order and the Christian Brothers have established themselves. In 1901, Methodists, Presbyterians, Baptists, United Brethren and Congregationalists formed an evangelical union and apportioned the mission field as the friar orders had done several centuries before. The census of 1918 shows 2,771 Roman Catholic, 540 Aglipayan and 486 Protestant churches.

There were no public schools until 1863, when they were established by royal decree. In 1866, it was reported that over 230,000 children were attending the public schools. Before 1600 a school had been established by private bequest, which in 1601 became the College of San José and was in charge of the Jesuits. The Jesuits also established the college of San Ignacio, and the



BY COURTESY OF THE CANADIAN PACIFIC STEAMSHIPS

NATIVE WOMEN OF THE PHILIPPINES GOING TO MARKET IN AN OX-CART

religious orders had seminaries and primary schools. More pretentious was the college of Santo Tomás, founded by the Dominicans early in the 17th century; it was declared a royal university in 1645, and still exists—the oldest university under the American flag. In the same century the Dominicans founded the school of San Juan de Letrán, which still exists. English was made the medium of instruction in 1923.

Very soon after the U.S. occupation, the first American public schools were opened, the first teachers being soldiers. In 1901, 1,000 teachers were sent from the United States to teach and to train Filipino teachers. Instruction has been from the beginning in English, with the consequence that now more Filipinos use English than used Spanish during the old régime. The vice governor is the secretary of public instruction, and under him is the bureau of education. During the American period over 600,000 children have completed the primary grade, about 170,000 the intermediate grades, and over 16,000 have graduated from the high schools. A prominent feature has been vocational and industrial training, compulsory after the first grade. In 1925–26, there were 7,459 public schools (enrolment, 1,108,955). That year there were 311 American teachers (112 male) and 25,193 Filipino teachers (14,840 male). In 1927, the total enrolment in 5,993 primary and 1,242 intermediate schools was 1,097,127. The University of the Philippines was founded by virtue of an act of the Philippine legislature of June 18, 1908. (*See* MANILA.) In 1926, there were 699 private schools, with a total enrolment of 88,001 (50,276 males). Among the more pretentious non-sectarian institutions are the Far Eastern college, the University of Manila and the National university. (*See* MANILA.) There are now over 4,000 school libraries with almost 950,000 books. Private and public welfare agencies are supervised by the Public Welfare Board. In 1926, there were 34 Government hospitals, with 45,046 patients; and 943 Government dispensaries, which treated 924,861 people.

Commerce and Business.—In 1897, imports were valued at approximately $9,600,000, and exports at $22,083,000; and in 1926, at $118,299,000 and $136,884,500 respectively. In 1927, the whole foreign trade was valued at $271,500,000. In 1927, the total trade with the United States was valued at $187,500,000 (69·09%). The principal items imported in 1926 were: cotton goods ($28,235,000) and iron and steel ($13,521,000). The principal exports were: sugar ($32,229,500); abacá ($32,142,000); coco-nut oil ($22,345,000) and copra ($18,586,500). In 1913 the Underwood Tariff Act abolished all duties between the United States and the Philippines. In 1926, there were, in addition to the Philippine National Bank, seven other domestic banks and four foreign banks and trust companies. Their resources totalled almost $122,800,000.

Finance and Revenues.—The national wealth of the Philippines was estimated at 5,495,482,000 pesos in 1923. Money is on a gold basis, the unit being the peso, which is stabilized at 50 cents U.S. The parity of the silver peso with the theoretical gold peso (the latter being the unit of value in the Philippine Islands, consisting of $12\frac{9}{10}$ grains of gold, $\frac{9}{10}$ fine) is maintained by the gold standard fund, which must not be less than 15% of the money of the Philippine Islands in circulation and available therefor; a percentage to be increased until it equals 25% of the total circulation. The standard gold fund balance in 1926 was about 21,700,000 pesos. The subsidiary coinage consists of one, five, ten, 20 and 50 centavo pieces (one centavo being equal to U.S. ½ cent). On Dec. 31, 1927, the bonded indebtedness of the insular, provincial and municipal governments was 167,985,000 pesos, and the sinking funds were approximately 38,543,000 pesos. In 1926 insular taxation amounted to approximately 59,232,000 pesos; city of Manila taxation, to 4,998,000; provincial taxation, to 10,946,000; and municipal taxation to 12,222,000 pesos. Customs collections in 1926 were approximately 21,180,000 pesos; internal revenue taxes, 54,544,000; income tax (1925), 2,343,000; and real estate tax, 14,537,000 pesos. The budget estimate in 1927 was: income, 73,153,100 pesos; expenditures 71,918,589. Receipts and expenditures of the Insular Government for 1926 amounted to 83,801,854 and 97,633,642 pesos respectively.

Government and Administration.—When Spain colonized the Philippines the natives were living under loose but fairly well crystallized forms of government, the primary unit of which was called "barangay." Society was composed of three classes, viz., serfs, freemen and nobles, and distinct rules governed each class. The Spaniards with great acumen organized their government partly on the native structure, with a governor general as supreme political chief, an *audiencia* or supreme court, provincial or district governments and municipal governments. Immediately upon conquest, tributes were levied on the natives, who were also given in *encomienda* to the *conquistadores*, officials and favoured

Spaniards. In the 19th century there were rather radical changes in the government. The Philippines were represented in the Spanish Cortes or parliament in 1810, 1812, 1820–23 and 1836–37.

The Spanish colonial government ceased in 1898, and was succeeded by a military government under the United States. In Jan. 1899, President McKinley appointed the Schurman Commission, which advised the reorganization of municipalities. In April 1900, President McKinley appointed the first Philippine Commission, which submitted all proposed laws to the military governor. Among the first 47 proposed by it and passed within the first few months, the fifth provided for a civil service, which was considerably in advance of that in the United States at that time. Military government ceased on July 4, 1901 (except in certain specified regions where it was maintained until July 4, 1902), at which time Judge Taft became the first and only civil governor of the Philippines; after his term the title was changed to governor general. The government was made directly dependent on the secretary of War, who organized the Bureau of Insular Affairs as his immediate agent. This bureau is still in existence and all Philippine matters that need attention in the United States pass through it. In 1901 the membership of the Philippine Commission was increased to seven by the appointment of three additional members, all Filipinos. Shortly afterward, four departments of government were created, viz., interior, commerce and police, finance and justice, and public instruction, each with a member of the Philippine Commission as its secretary. In 1901 and 1902, the organization of provincial and municipal governments continued, and by Nov. 10, 1902, 37 provinces had been organized.

On July 1, 1902, Congress enacted a provisional enabling or organic act under which the islands were governed until Aug. 29, 1916, when the Jones Bill was passed. The organic act of 1902 provided for a general election and the creation of a popular legislative chamber, the Philippine assembly, which was to become the lower house of a Philippine legislature, the Philippine Commission to be the upper house. An election of members of the Philippine assembly was held on July 30, 1907. All exclusive legislative power was taken from the Philippine Commission and lodged in the legislature, except for territory inhabited by Moros or other Philippine non-Christians. Two resident commissioners were appointed to the Congress of the United States, with power to speak on legislation affecting the Philippines but with no vote. In 1908, the Philippine Commission was increased by one more Filipino member. In Oct. 1913, President Wilson appointed a new commission, composed of five Filipinos and four Americans. On Aug. 29, 1916, the Jones Bill created a legislature with a Senate of 24 members and a House of Representatives of 91 members (now 92) all elected by popular suffrage except two senators and nine representatives, appointed by the governor general to represent the non-Christian provinces of Nueva Vizcaya, Mountain Province, Agusan, Bukidnon, Cotobato, Davao, Lanao, Sulu and Zamboanga. By virtue of the Jones Bill there are now six executive departments, each under a secretary, who is assisted by an under secretary. All these officials except the secretary of public instruction are Philippine citizens. With the exception of the governor general, vice governor (who is also secretary of public instruction), auditor, deputy auditor, the directors of the Philippine constabulary and of the bureaux of education, agriculture, forestry, science, public works, and the coast and geodetic survey, all the departmental secretaries and directors of bureaux are (1929) Filipinos.

With the consent of Governor General Harrison, a Council of State, consisting of the president of the Senate, the speaker of the House, and the six departmental secretaries, was formed to pass on proposed legislation and policies of the Government. During the rest of Harrison's term, this organization was accepted as a legitimate part of the Government, but under Harrison's successor, Maj.-Gen. Wood, it ceased to function, through the resignation of its Filipino members. It was re-established by Governor General Stimson in 1928 and enlarged to include the majority floor leaders of the Senate and of the House, thus making it even more representative than the former Council.

The judiciary consists of a supreme court, composed of a chief justice (a Filipino) and eight associate justices (three Filipinos), all appointed by the president of the United States with the consent of the U.S. Senate; a court of first instance for each of the 26 judicial districts; the municipal court of Manila; and justice of peace courts for each municipality.

There are 48 provinces and sub-provinces (excluding Manila which has the rank of a province), of which 39 are regularly constituted and governed by an elective governor, who is the executive, and a provincial board composed of two elective members and the provincial treasurer, which is the legislative branch of the province. In the specially organized provinces, the governors and lieutenant governors are appointive officials. The municipal government consists of a president, vice president and a municipal council. In 1918 there were 820 municipalities, 88 townships, 213 municipal districts and 16,307 barrios.

History.—The Philippine archipelago first became known to Europeans on March 16, 1521, through Ferdinand Magellan (*q.v.*). But there are authentic Chinese accounts of trading voyages as early as the 10th and 13th centuries, and the contact probably went back much further. A Hindu influence undoubtedly came by way of the Malay peninsula, Java and other islands nearby, and probably reached back to the early centuries of the Christian era. The Hindus influenced the life of the people intimately. Many Sanskrit words in the languages and dialects of the people of the Philippines and the forms of the letters used at the time of their discovery by the Spanish, indicate this.

The second, third and fourth Spanish expeditions were those of García Jofre de Loaisa, of Alvaro de Saavedra and of Ruy López de Villalobos. The next expedition, that of Miguel López de Legazpi (1564–72) was despatched, like its predecessor, from New Spain, but it was far more carefully planned. Leaving Puerto de Navidad in New Spain, on Nov. 20, 1564, Legazpi reached Cebu in April 1565, where the first permanent settlement was made early in May. But Legazpi, with inadequate forces and resources, meeting prolonged hostility from the Portuguese, who swarmed through the region, at last (1569) moved his main forces to the island of Panay, hoping thereby to have better protection. In 1571 Legazpi made Manila the administrative centre. Thereafter the conquest of Luzon proceeded rapidly, at first principally under Juan de Salcedo, the precocious young grandson of Legazpi. All of the archipelago except the Moro islands of Mindanao, the Sulu archipelago, and Palawan were in fairly peaceful possession of the Spaniards before 1600. In June, 1572, the city of Manila was formally established. In 1574 Manila was attacked by the Chinese Limahong, but he was forced to retire from the island and from the entire group. Several of the provisional governors were churchmen who played into the hands of the ecclesiastics, or catered to their own order.

The Spaniards were accepted easily, even hospitably in many cases, and those coming into closest contact with them began almost immediately to take on the veneer of a superior culture. The conquest was especially easy along the coast and in the low interiors where the Spaniards first went. The principal opposition at Manila in 1570 came from Mohammedans. But that faith was not yet strongly entrenched in Luzon. It was quite different in Mindanao and at various other points in the south. The Spaniards were instinctive enemies of these people, for they had had a seven-century fight in Spain against Mohammedanism. To them the word "Moro" meant Mohammedan, or Moor. Accordingly, they dubbed the Malayan Mohammedans *Moros* and by this name they are still known. In 1574, the Moros of the Rió

Grande de Mindanao offered submission. In 1578–79 Francisco de Sande (1575–80) conducted a fairly successful expedition against the Moros, but the Spaniards were unable to gain any lasting advantage. Until 1837 piratical raids were almost continuous. The Moros ravaged the coasts far and wide, even threatening Manila itself. The Moros joined often with the Dutch after the latter began to infest oriental waters. In 1848, on Balanguingingui island, Governor Narciso Clavería y Zaldua won the most decisive victory ever gained over the Moros. In 1850, Governor Antonio de Urbiztondo y Eguía destroyed the strongholds on Tonkil island and the next year stormed and captured the town of Jolo. This ended the real power of the Moros.

SALT WORKS AT MALABON

During the interim between Magellan's discovery and the settlement of Manila, the Portuguese actively contested Spanish right to the archipelago. Their hostility ceased only with the union of Spain and Portugal (1580–1640). In 1577 Sir Francis Drake started on the voyage which brought him to the Philippines at Mindanao. Again, in 1587, Thomas Cavendish sailed to the Moluccas and thence back to California to intercept the rich galleon "Santa Ana." He then went to the Philippines, where he tried in vain to capture the ship-yard at Iloilo.

The Dutch came next. Their primary object was trade rather than colonies. In 1596–97, Admiral Houtman opened trade with Holland, and during the years 1598–1600, the expedition under Neck and Waryck traded in the Moluccas. In 1600, Oliver van Noordt reached Philippine waters, where he committed various depredations. Dutch vessels now traded for spices and other oriental wares in the Moluccas, harried the coasts and waters of the Philippines and attacked Portuguese, Spanish, Japanese and Chinese shipping. In 1610, Governor Juan de Silva defeated and killed the Dutch admiral, Francis de Wittert, at Playa Hondo, near Manila, and captured part of his fleet. In 1640, the Dutch captured Malacca and in 1662 they permanently occupied the Moluccas. Their attacks in the Philippines gradually ceased.

With Legazpi had come five Augustinians; in 1577 came the Franciscans; in 1580, the Jesuits; in 1587, the Dominicans; and 1605, the Augustinian Recollects. It was the intention of Spain to replace the friars by secular parish priests whenever any mission assumed the character of a parish. But the friars, desirous of retaining their holdings and power, fought secularization and it was never carried out in its entirety. The friars became the storm centre of the gradually increasing Filipino demand for change; the insurrection of 1896 was directed principally against them; and during the later insurrection against the United States they suffered many indignities.

In 1762 a British expedition reached Manila on Sept. 22, found the Spanish but ill prepared, and on Oct. 5, captured the city. By the Treaty of Paris in 1763, Manila was restored to Spain.

The last Manila galleon left the Philippines in 1811 and returned in 1815. Thereupon the trade was taken over by private persons, exports to the value of 750,000 pesos were allowed and three other ports besides Acapulco were opened to it, namely San Blas, Guayaquil and Callao. In 1766, however, the crown had allowed direct trade between Spain and Manila by one national vessel annually. In 1785, the Royal Company of the Philippines began to trade between Manila and Cadiz; the company ceased to exist in 1830.

In 1809, an English commercial house was permitted to establish itself in Manila, and in 1814 a like privilege was extended to all foreigners, but as a rule, Spaniards were still jealous of foreigners and reactionary decrees in 1828 and 1840 forbade them to sell goods at retail or to do any business in the provinces. The vacillating Spanish policy is seen again in the opening of seven ports to foreign trade in 1830 and their closing the next year. In 1837, Manila was reopened to foreign trade, Iloilo and Cebu in 1855 and 1863. In 1842 there were 39 Spanish shipping and commercial concerns in Manila and about a dozen foreign houses. Various Governments maintained consuls, among them Great Britain and the United States.

During the first half of the 19th century, there were only 2,000 to 5,000 Spaniards in the archipelago. Spanish was spoken by some of the natives, principally in Manila and a few other important centres, but the friars had made comparatively little effort to inculcate a knowledge of Castilian. There was no homogeneity among the several native peoples, very largely because of the different languages. Partly because of these conditions, insular representation in the Spanish Cortes carried little meaning or a mistaken one to the mass of the population. After the building of the Suez canal, in 1869, ambitious Filipino youths went to Spain and other countries for study. The first daily newspaper was *La Esperanza* (1847). *La Solidaridad* was founded in 1888 in Barcelona, by Graciano López Jaena in the interest of Filipino propaganda, and throughout its course urged reforms both in religion and government. One of its foremost contributors was the precocious Chinese mestizo, José Rizal y Mercado. The Filipinos had had ample grounds for complaint, especially since 1872. That year some 200 native soldiers at the Cavite arsenal revolted, killed their officers and shouted for independence. Plans for a similar demonstration in Manila failed. The insurrection was quickly suppressed, and led to wholesale arrests, life imprisonment and the execution, among others, of three Filipino secular priests, whose connection with the uprising has never been satisfactorily explained.

Meanwhile the gradually expanding idea of Filipino nationality began to manifest itself. The campaign of Rizal, Marcelo del Pilar, López Jaena and Apolinario Mabini, leaders in the "Young Filipino Party," was a protest against both the domination of the friars and economic and administrative caciquism. These aspirations met a sympathetic reception from several governors. But other Spaniards, especially the friars, were diametrically opposed; and much of the old easy and cordial intercourse between the two peoples was changed. Rizal threw himself into the propaganda with eagerness. In 1891 he founded at Hong-kong an organization called the Liga Filipina, and in 1892, formed a branch at Manila. He was arrested in 1896 at Barcelona, returned to the Philippines, given a farcical trial and executed on Dec. 30, 1896. At about the time of Rizal's establishment of the Liga Filipina there was also founded an organization called "Supreme Worshipful Association of the Sons of the People," which is generally called the *Katipunan*. The organization was altogether Tagalog and is said to have numbered anywhere from 100,000 to 400,000 members. On Aug. 26, 1896, the actual insurrection broke out. "The cry of Balintawak" is the name given to the first hostilities by the Filipinos. The centre of the revolt was at Cavite, where Emilio Aguinaldo first came into prominence. Spain sent over reinforcements until there was an army of 28,000 besides a few loyal regiments of native soldiers. A stiff campaign of 52 days brought the defeat of the insurgents, but upon the execution of Rizal, the insurrection broke out again and spread to the provinces of Pangasinan, Zambales and Ilocos. Fernando Primo de Rivera opened negotiations with Aguinaldo and concluded with the insurgents the pact of Biac-na-Bató. Accordingly, Aguinaldo left for Hongkong on Dec. 27, 1897. With the blowing up of the "Maine" on Feb. 15, 1898, actual hostilities broke out between Spain and the United States. (*See* SPANISH-AMERICAN WAR.) The Filipinos, who had declared their independence of Spain on June 12, 1898, proclaimed a provisional republic with Aguinaldo as president, and on Sept. 9, 1898, made their capital at Malolos, with Apolinario Mabini, "the mouthpiece of the revolution," as Aguinaldo's chief adviser. On Sept. 15, a revolutionary assembly met and on the 29th ratified Filipino independence. In November and December, revolutionary tribunals were organized in the Bisayas.

A PHILIPPINE POTTER AT WORK

THE PHILIPPINES UNDER THE UNITED STATES

Relations between the Americans and the Filipinos were unfriendly and steadily grew worse. On Jan. 23, 1899, the Malolos Constitution, by virtue of which the Philippines were declared a republic, and which had been approved by the assembly on Nov. 29, and by Aguinaldo on Dec. 23, was proclaimed. Aguinaldo, who had been president of the provisional government, was elected president. On the night of Feb. 4, the inevitable conflict between the Americans and Filipinos surrounding Manila was precipitated. Morning found the Filipinos, who had fought bravely, even recklessly, defeated at all points. While the fighting was in progress, Aguinaldo issued a proclamation of war against the United States. On Feb. 6, the U.S. Senate ratified the treaty, and reinforcements were immediately sent to the Philippines. Antonio Luna, the best trained military man among the Filipinos, was given charge of military operations, but seems to have been greatly hampered by the jealousy and distrust of Aguinaldo, which he fully returned. Luna was murdered, and on March 31, 1899, Malolos was captured by the American forces. The Filipino Government fled northward. In Nov. 1899, the Filipinos resorted to guerrilla warfare, with all its devastating, barbaric features. The capture of Aguinaldo by Gen. Frederick Funston in March 1901 virtually ended the real insurrection, although the last surrender was that of Gen. Miguel Malvar in Samar on April 16, 1902. The major operations of the insurrection were conducted in Luzon, and throughout the army was assisted materially by the Makabebe scouts, who remained loyal to the Americans.

Negotiations looking toward the purchase of friar lands (some 400,000 ac.) were carried on personally with the pope by Mr. Taft. The contract for the purchase for approximately $7,250,000 was signed on Dec. 22, 1903. Since then a considerable portion of the estates—much of them fine agricultural land—have been sold to Filipinos. The papacy also assigned an American archbishop and American bishops to the sees in the archipelago and accepted the doctrine of the separation of state and church. In 1905, Mr. Taft, as secretary of War, and a party of senators and representatives visited the islands. On Oct. 16, 1907, the legislature was convened by Mr. Taft. It voted to continue the use of Spanish jointly with English as an official language until 1913, when English was to become the sole official language. On Aug. 6, 1909, Congress, by the Payne Bill, granted a fuller measure of free trade between the U.S. and the Philippines. The Underwood Tariff Act of 1913 brought in complete free trade between the U.S. and the Philippines.

During the term of W. Cameron Forbes as governor general (Nov. 11, 1909–Oct. 6, 1913), emphasis was laid upon the construction and maintenance of roads and bridges; the extension of education and the construction of concrete schoolhouses; agriculture; the eradication of rinderpest; the development of Baguio as a summer capital; and on health. The proportion of Filipinos in the civil service in 1903 was 49% of the whole, 71% in 1912, almost 79% in 1914, over 94% in 1919, and almost 98% in 1926. Under the first five American governors there were conflicts between the two houses of the legislature, and for two years the Philippine assembly failed to vote an appropriation for carrying on the functions of government.

On his arrival in 1913, Governor General Harrison delivered a message from the president promising that "every step we take will be taken with a view to the ultimate independence of the Islands and as a preparation for that independence." On April 7, 1900, President McKinley had said in his instructions to the Taft Philippine Commission: ". . . the Commission should bear in mind that the government which they are establishing is designed not for our satisfaction or for the expression of our theoretical views, but for the happiness, peace, and prosperity of the people of the Philippine Islands. . . ." Assuming that the time had come to give greater autonomy to the Filipinos, President Wilson by new appointments gave them a majority on the Philippine Commission. On Dec. 31, 1927, there were 470 Americans and 18,246 Filipinos in the Government service.

In 1916, the Government purchased the stock of the Manila Railway Company; and that same year there was created the Philippine National Bank, in which the Government held all but a very small percentage of stock. By an act approved March 10, 1917, the National Coal Company was created as a private company, with the Government owning most of the stock. Other similar organizations were the National Cement, Iron and Petroleum Companies. Power to vote the Government stock was eventually vested in a board of control consisting of the governor general, the president of the Senate and the speaker of the House.

One of President Harding's first acts was to despatch the Wood-Forbes mission to make a survey of existing conditions. It reported that the immediate granting of independence would be premature and advised that the United States should not be left in a position of responsibility without authority—this latter referring specifically to the laissez-faire policy pursued by Harrison. Gen. Wood was made Governor General on Oct. 5, 1921. Until his death (Aug. 7, 1927), he was the centre of many storms.

The Council of State ceased to exist on July 17, 1923, the departmental secretaries, with the exception of the secretary of public instruction (an American), resigning both in their capacity as secretaries and as members of the Council of State. Wood accepted the resignations, and thereafter governed through the under secretaries. After considerable controversy, Wood abolished the board of control of the national companies by an executive order of Nov. 9, 1926. Appeals made to the Philippine and U.S. courts sustained Wood's action.

In 1926 President Coolidge sent Col. Carmi A. Thompson to the islands to make an investigation of conditions. His report, dated Dec. 4, 1926, recommended that the breach between the legislative and executive branches of the government be healed; that the granting of absolute independence be postponed; that an independent department be established for the administration of the Philippine Islands and other overseas territory; that the governor general be provided with the necessary civil advisers to relieve him from the necessity of selecting them from the U.S. army (as Wood had been compelled to do); that Mindanao and Sulu should not be separated from the Philippines but that American control be strengthened in the Moro country; that the Federal Reserve System be extended to the Philippines; that one or more Federal land banks be established to provide loans at reasonable interest to farmers; that the Jones Act be not changed as yet; and that the Philippine legislature should amend the land laws in order to attract capital and business experience to develop production of coffee, rubber and other tropical products. Under the short régime of Governor General Henry L. Stimson a more responsible type of government was instituted and the confidence of Filipino leaders was regained. In August, 1928, Stimson appointed his cabinet from men possessing the confidence of the party that triumphed in the last election, which meant a return to party government. He also re-created the Council of State. Appropriations for the necessary civil advisers were secured, and other aids to cooperation between the executive and legislature were added. He secured the passing of a more liberal corporation law, opposed the demand in the United States for further discrimination in duties against Philippine products, advised a revision of the land laws and the establishment of a budget. Stimson was recalled in March, 1929, to become Secretary of State in the Hoover cabinet and in May President Hoover appointed Dwight W. Davis, former Secretary of War, to succeed him.

The Palmas island arbitration case instituted in 1925 between the Netherlands and the United States was decided in favour of the former country in 1928.

Bibliography.—For lists of titles and critical notes, *see* A. P. C. Griffin, *A List of Books on the Philippine Islands in the Library of Congress* (Washington, 1903), with references to periodicals; J. A. PHILIPPOPOLIS (Bulg. *Plovdiv*), the second town of Bulgaria, capital of the department of the same name, and seat of an archbishopric, is situated on the right bank of the Maritsa, 96 m. E.S.E. of Sofia, and on the main Belgrade-Constantinople railway. Pop. (1926) 85,188, the majority being Bulgars, the remainder chiefly Turks, Armenians, Jews and gypsies. The former Greek colony is now almost extinct. The city lies on and between seven granite rocks which rise abruptly out of the flat and very fertile plain of the Maritsa; the southern Balkans are distant about 25 m., the northern Rhodopes about twelve. The old Turkish Konak, another park, and the gymnasium are near the Maritsa. The "Gate of Hissara" in the old walls is noteworthy. The new town spreads south and south-west of the old.

Philippopolis is a wealthy commercial city, centre of the trade in tobacco, wheat, silk and attar of roses of south Bulgaria. There is also a growing industry in flour-mills, tobacco factories, beer, soap, leather, ink, furniture and sugar.

History.—Eumolpia, a Thracian town, was captured by Philip of Macedon and made one of his frontier posts; hence its name of Philippopolis. Under the Romans, Philippopolis, or Trimontium, was the capital of Thracia. It is said that 100,000 persons were slain when it was captured by the Goths. In 762 it was in ruins when the Emperor Constantine Copronymus settled large colonies of Armenian Paulicians in and around it as frontier guards. It recovered its prosperity under the later Roman Empire, and excited the admiration of the crusaders. Frederick Barbarossa [sic: "Bar-" at column end] to Renier of Trit. The inhabitants at first welcomed him, but the next year the Greeks declared for the Byzantine emperor, whereupon the Armenians betrayed the city to the Bulgarian tsar, Kaloyan, who massacred its Greek inhabitants, and razed the city to the ground. It recovered again, and became of extreme importance as the centre from which the Bogumils (*q.v.*) derived their doctrines through Armenian teachers. It was retaken by the Greeks in 1262, by the Turks in 1363. It was occupied by Russian troops in 1878, and under the Treaty of Berlin was made capital of the autonomous province of Eastern Roumelia, being united with Bulgaria in 1885 (*see* BULGARIA: *History*). In 1928 it was severely damaged by earthquake.

PHILIPPUS, MARCUS JULIUS, Roman emperor A.D. 244 to 249, often called "Philip the Arab," was a native of Bostra in Arabia Trachonitis. Having entered the Roman army, he rose to be praetorian praefect in the Persian campaign of Gordian III., and, inspiring the soldiers to slay the young emperor, was raised by them to the purple (244). Of his reign little is known except that he celebrated the secular games with great pomp in 248, when Rome was supposed to have reached the thousandth year of her existence. A rebellion broke out among the legions of Moesia, and Decius, who was sent to quell it, was forced by the troops to put himself at their head and march upon Italy. Philip was defeated and slain in a battle near Verona. According to Christian writers, he was a convert to Christianity.

See Aurelius Victor, *Caesares*, 28; Eutropius, ix. 3; Zonaras, xii. 19.

PHILIPS, AMBROSE (*c.* 1675–1749), English poet, was born in Shropshire of a Leicestershire family. He was educated at Shrewsbury school and St. John's college, Cambridge, of which he became a fellow in 1699. His *Pastorals* opened vol. vi. of Tonson's *Miscellanies* (1709), which also contained the pastorals of Pope. Philips was a stanch Whig, and a friend of Steele and Addison. In Nos. 22, 23, 30 and 32 (1713) of the *Guardian* he was injudiciously praised as the only worthy successor of Spenser. The quarrel between Pope and Philips which ensued is described by Samuel Johnson as a "perpetual reciprocation of malevolence." Philips had been made justice of the peace for Westminster, and in 1717 a commissioner for the lottery, and when Boulter was made archbishop of Armagh, Philips accompanied him as secretary. He sat in the Irish parliament for Co. Armagh, was secretary to the lord chancellor in 1726, and in 1733 became a judge. He died in London on June 18, 1749.

His contemporary reputation rested on his pastorals and epistles, particularly the description of winter addressed by him from Copenhagen (1709) to the earl of Dorset. In T. H. Ward's *English Poets*, however, he is represented by two of the simple and charming pieces addressed to the infant children of Lord Carteret and Daniel Pulteney. These were scoffed at by Swift as "little flams on Miss Carteret," and earned for Philips from Henry Carey the nickname of "Namby-Pamby."

Philips's works are an abridgment of Bishop Hacket's *Life* of John Williams (1700); *The Thousand and One Days; Persian Tales* . . . (1722), from the French of F. Pétis de la Croix; three plays: *The Distrest Mother* (1712), an adaptation of Racine's *Andromaque; The Briton* (1722); *Humfrey, duke of Gloucester* (1723). Many of his poems, which included some translations from Sappho, Anacreon and Pindar, were published separately, and a collected edition appeared in 1748.

PHILIPS, JOHN (1676–1708/09), English poet and man of letters, son of Dr. Stephen Philips, archdeacon of Shropshire, was born at Bampton, Oxfordshire, on Dec. 30, 1676. He was educated at Winchester and Christ Church, Oxford. His poem, *The Splendid Shilling,* was called by Addison in *The Tatler* "the finest burlesque poem in the British language." Harley and St. John commissioned him to write a Tory counterblast (*Blenheim*) to Joseph Addison's *Campaign. Cyder* (1708), one of the earliest of the great didactic poems of the 18th century, is modelled on the *Georgics* of Virgil. *Cerealia, an Imitation of Milton* (1706), although printed without his name, may safely be ascribed to him. In all his poems except *Blenheim* he inserted a eulogy of tobacco. Philips died at Hereford on Feb. 15, 1708/09.

See The Whole Works of . . . *John Philips* . . . *To which is pre-*

Philips (1927), ed. M. G. Lloyd Thomas; and Johnson's *Lives of the Poets*.

PHILIPS, KATHARINE (1631–1664), English poet, daughter of John Fowler, a merchant of Bucklersbury, London, was born on Jan. 1, 1631. In 1647 she married James Philips, a Welsh royalist. Her home at the Priory, Cardigan, became the centre of a "society of friendship," the members of which were known to one another by fantastic names, Mrs. Philips being "Orinda," her husband "Antenor," Sir Charles Cotterel "Poliarchus." The "matchless" Orinda, as her admirers called her, posed as the apostle of female friendship. Jeremy Taylor dedicated to her his "Discourse on the Nature, Offices and Measures of Friendship," and Cowley, Henry Vaughan, Roscommon and the earl of Cork and Orrery all celebrated her talent. She died of smallpox on June 22, 1664. The literary atmosphere of her circle is preserved in the excellent *Letters of Orinda to Poliarchus*, published by Bernard Lintot in 1705 and 1709.

See E. W. Gosse, *Seventeenth Century Studies* (1883). *Poems, By the Incomparable Mrs. K. P.* appeared surreptitiously in 1664 and an authentic edition in 1667. *Selected Poems,* edited with an appreciation by Miss L. I. Guiney, appeared in 1904. The best modern edition is in Saintsbury's *Minor Poets of the Caroline Period* (vol. i., 1905).

PHILIP THE BOLD (1342–1404), duke of Burgundy, fourth son of John II. of France and Bonne of Luxemburg, was born on Jan. 15, 1342. He earned his surname by his bravery on the field of Poitiers. He accompanied King John into captivity in England. In 1360 he received the title of duke of Touraine, and in June 1363 was entrusted with the government of Burgundy, which John had united to the crown at the death of the last duke of the Capetian family, Philip of Rouvre, in 1361. In September 1363 John made Philip duke of Burgundy, and first peer of France. The donation was ratified at the accession of Charles V. of France; he took possession of the duchy at the end of 1364. Charles appointed him (in 1366) his lieutenant in Champagne and married him in 1639 to Margaret, daughter and heiress of Louis of Mâle, count of Flanders, and widow of Philip of Rouvre.

Philip proved a faithful ally to Charles. He took part in the almost bloodless campaign against the duke of Lancaster, who had landed at Calais; in 1377 he took several towns in French Flanders from the English; and in 1379 relieved Troyes, which had been besieged by the English. On Charles's death Philip found himself, with his brothers, the dukes of Anjou and Berry, in charge of the government of France in the name of Charles VI., who was a minor; and in the absence of the duke of Anjou, who left France in 1382 to conquer the kingdom of Naples, Philip occupied the most powerful position in the realm. He persuaded the young king to intervene in Flanders, where the citizens of Ghent, whose rebellious spirit had necessitated Philip's intervention in 1379, had again revolted under Philip van Artevelde and had expelled Louis of Mâle. On Nov. 27, 1382, the Franco-Burgundian chivalry crushed the rebels at Rosebecke, and on his return the duke of Burgundy took part in repressing the popular movements which had broken out in Paris and other French towns. In 1383 an insurrection in Flanders supported by England gave rise to another French expedition; but in January 1384 the death of Louis of Mâle made Philip master of the countships of Flanders, Artois, Rethel and Nevers; and in the following year the citizens of Ghent decided to submit. At this period Philip sought to ingratiate himself with the emperor by giving two of his daughters in marriage to two princes of the house of Bavaria; he also took an important part in bringing about the marriage of a princess of the same family, Isabel, to King Charles VI.

Hostilities, however, were renewed between France and England. A formidable expedition was prepared under the direction of the duke of Burgundy, and a fleet of 1,400 sail assembled at Sluys; but the enterprise failed owing to the dilatoriness of the duke of Berry. The fatiguing and inglorious expedition in the Netherlands weakened Philip's credit with his nephew, who on his return declared himself of age and confided the government to the ancient councillors of his father, the "Marmousets." The king's madness (1392) restored his uncles to power, and particularly Philip, who after assuring peace by treating with the duke of Brittany and by concluding a truce of twenty-eight years with England, made strenuous efforts to put an end to the Great Schism, visiting Pope Benedict XIII. at Avignon in 1395 in the hope of obtaining a voluntary resignation from him. For the discords in the king's council *see* CHARLES VI. For a brief period Philip was dispossessed of authority, but he regained it in 1402 and kept it till his death (April 27, 1404). The cathedral of St. Bénigne at Dijon contains his remains, and his tomb (formerly in the Chartreuse of Dijon) is in the Hôtel-de-ville. Philip appears to have governed his territories with sagacity and a certain moderation. He granted numerous privileges to the inhabitants of Dijon, and created in 1386 two *chambres des comptes,* one at Dijon and the other at Lille. He was, in the phrase of a contemporary, "kindly and amiable to high and low and those of middle rank, liberal as an Alexander, noble and pontifical, in court and state magnificent." (R. P.; X.)

PHILIP THE GOOD (1396–1467), duke of Burgundy, son of John the Fearless, duke of Burgundy, and Margaret of Bavaria, was born at Dijon on June 13, 1396, and succeeded his father on Sept. 10, 1419. The assassination of John the Fearless (*q.v.*) drove his successor to the English side. In 1419 Philip signed with Henry V. of England the treaty of Arras, by which he recognized Henry as regent and future heir of the kingdom of France, and in 1420 gave his adherence to the treaty of Troyes. Early in December 1420 Philip entered Paris with the king of England, and subsequently took part in the defeat of the French at Mons-en-Vimeu. By a treaty concluded by Philip at Amiens in April 1423 with the dukes of Brittany and Bedford, John, duke of Bedford, married Philip's sister Anne, and Arthur of Brittany, earl of Richmond, became the husband of Philip's sister Margaret. A few years later discord arose among the allies. When the duke of Bedford besieged Orleans the inhabitants offered to surrender, but to the duke of Burgundy; whereupon Bedford retorted that "he did not beat the bushes for others to take the birds." When this speech reached Philip's ears he withdrew his troops in dudgeon, and concluded a truce with France (1429). Bedford succeeded in conciliating him and in 1430 Philip took part in the campaign against Compiègne.

But another conflict arose between the duke of Burgundy and the English. Jacqueline, countess of Hainaut (*see* JACOBA) the divorced wife of the duke of Brabant and the heiress of Holland and Zeeland, had married the duke of Gloucester, who attempted to take forcible possession of his wife's territories. Philip claimed Brabant as a bequest from his cousin Philip, the late duke, with the result that the Burgundians repulsed the troops of the duke of Gloucester, and Jacqueline was forced to recognize the duke of Burgundy as her lieutenant and heir. Moreover, the duchess of Bedford had died in 1433. Charles VII., who in spite of the efforts of the cardinal of Ste-Croix had hitherto refused to return to France, finally decided to take part in the conferences which were opened at St. Vaast d'Arras on Aug. 6, 1435. Philip agreed to recognize the king of France as his legitimate sovereign on condition that he should not be required to pay him homage during his lifetime. Charles solemnly craved pardon for the murder of John the Fearless and handed over to the duke the counties of Mâcon, Auxerre, Bar-sur-Seine and Ponthieu, and the towns on and near the Somme (Roye, Montdidier, Péronne), reserving the option of redeeming the Somme towns for 400,000 gold crowns. Philip faithfully served the king, aiding him in re-entering Paris and preparing an expedition against Calais, which, however, failed through the ill-will of his Flemish subjects (1436). In 1440 he paid the ransom of Charles of Orleans and married him to Mary of Cleves. In 1442 Philip conspired to give the duke of Orleans a larger share in the affairs of the kingdom.

Philip was frequently disturbed by the insubordination of the Flemish communes. He had to quell seditions at Liége (1430), Ghent (1432 and 1448), Antwerp (1435) and Bruges (1438). Shortly after the final defeat of the citizens of Ghent at Gavre (1453) Philip vowed that he would lead a crusade against the Turks, who had seized Constantinople. The expedition, however, did not take place, and was but a pretext for levying subsidies. In 1459 Philip sent an embassy under the duke of Cleves into Italy to

take part in the conferences preparatory to a fresh expedition against the Turks, but this enterprise likewise fell to the ground. In 1456 the duke of Burgundy had given an asylum to the Dauphin Louis (afterwards Louis XI.), who had quarrelled with his father and had been forced to leave France. Louis repaid his protector by attempting to sow discord in the ducal family of Burgundy, and then retired to the castle of Genappe in Brabant. At Charles VII.'s death, however, Philip was one of the first to recognize the new king, and accompanied him to Paris. During the journey Louis won over the seigneurs of Croy, the principal counsellors of the duke of Burgundy, and persuaded Philip to allow him to redeem the Somme towns for the sum stipulated in the treaty of Arras. This proceeding infuriated Philip's son Charles, count of Charolais, who prevailed upon his father to break his pledge and declare war on the king of France. On April 12, 1465, Philip handed over to his son the entire administration of his estates. The old duke died at Bruges on June 15, 1467.

Philip was a great lover of pomp and luxury and a friend of letters, being the patron of Georges Chastelain, Olivier de la Marche and Antoine de la Salle, and the founder of the collection of mss. known as the "Bibliothèque de Bourgogne" (now at Brussels), and also of the university of Dôle (1421). He administered his estates wisely; promoted commerce and industry, particularly in Flanders; and left his son a well-lined treasury. He was thrice married. in 1409 to Michelle (d 1422), daughter of Charles VI of France; in 1424 to Bonne of Artois (d. 1425); and in 1429 to Isabel (d. 1472), daughter of John I, king of Portugal, when he founded the order of the Golden Fleece. He was succeeded by Charles, afterwards known as Charles the Bold, his only surviving son by Isabel. (R. P.; X.)

PHILISTINES. "Philistine" was the general name for the people of Philistia (Ass. *Palaštu, Pilištu;* Eg. *p-r-s-t*), a district embracing the rich lowlands on the Mediterranean coast from the neighbourhood of Jaffa (Joppa) to the Egyptian desert south of Gaza On the subsequent extension of the name in its Greek form, Palaestina, *see* PALESTINE.

According to biblical tradition the Philistines are the remnant of Caphtor (Jer. xlvii. 4, Amos ix. 7), and the Caphtōrīm drove out the aboriginal Avvim from Gaza and district, as the Horites and Rephaim were displaced by Edom and Ammon (Deut ii. 23). These Caphtōrīm, as well as Ludim (Lydians) and other petty peoples, apparently of the Delta, are once reckoned to Egypt (Gen. x. 14). By Caphtor the Septuagint has sometimes understood Cappadocia, which indeed may be valid for its age, but the name is to be identified with the Egyptian K(a)ptar, which in later Ptolemaic times seems to mean Phoenicia, although the earlier *Keftiu* connoted Crete, and possibly "the south Anatolian coast as far as Cilicia" (Hall). The Cherethites, associated with the Philistine district (1 Sam. xxx. 14, 16, Ezek xxv. 16, Zeph ii. 5 *seq*), are sometimes recognized by the Septuagint as Cretans, and, with the Pelethites, they form part of the royal bodyguard of Judaean kings (2 Sam. viii. 18, xv. 18, xx. 7, 1 Ki. i. 38, 44; in 2 Sam. xx. 23 the Hebrew text has Carites).

The earliest occurrence of the name "Philistines" outside the Old Testament is in Egypt, where the Purasati (Pulesati) are one of a great confederation from north Syria, Asia Minor and the Levant, which threatened Egypt in the 20th dynasty. They are not among the hordes enumerated earlier by Rameses II. or Merneptah, but in the eighth year of Rameses III. (*c.* 1194 B C); the Purasati (Pulesati) take part in a widespread movement on land and sea. The Syrian States were overwhelmed and the advance upon Egypt seemed irresistible. Rameses, however, collected a large fleet and an army of native troops and mercenaries and claimed decisive victories. The Egyptian monuments depict the flight of the enemy. The sequel of the events is not known, though about a century later the Zakaray are found at Dor, and treat with scant respect the suzerainty of Egypt.

The Egyptian monuments represent the Purasati with a very distinctive feather head-dress resembling that of the Lycians and Mycenaeans. Their general physiognomy is hardly Cilician or Hittite, but European, especially Greek. They fought with a broad-sword and carried a round shield. On archaeological grounds the Purasati were not Mycenaeans from Crete, despite tradition, but rather from Asia Minor (Lycia, Caria), though they may have passed some time in Crete.

Palestine and the West.—The Philistines appear in the Old Testament as a Semitic or at least a Semitized people. Both the language and the religion were Semitic. The male god Dagon has his partner Astarte (*qq.v.*), and Baal-zebub, a famous oracle of Ekron (2 Ki. i) resembles the local "baals" of Palestine. Philistia seems to be completely Hellenized after the Persian age; but it is not certain that Greek culture pervaded all classes; foreign influence probably always made itself felt upon the coast-towns The use of the term ἀλλόφυλοι in Maccabaean and later writings (*cf.* the contemptuous hatred of Ben Sira, Ecclesiasticus l. 26, and the author of Jubilees xxiv. 30 *sqq*) expresses the conditions of the Greek age and the Maccabaean wars The Mediterranean coast-land was always exposed to incursions of aliens; Carians appear as royal and temple guards at Jerusalem (2 Ki. xi. 4), and old Greek traditions tell of a Carian sea-power and relations between Philistia and Greek lands. Even the presence of Carians and Ionians in the time of Psammetichus I may be assumed, and as these are planted at Defneh it is noteworthy that this place is also closely associated with a Jewish colony (viz , Tahpanhes, Jer xliii., *seq*). In fact, Palestinian intercourse with the West is fairly continuous; and excavation at Beth-shan, Gezer, and other sites, has shown many important indications of Western influence, so that some authorities even recognize a "Philistine" pottery.

History.—The Philistines form a confederation of five cities (Ashdod, Ascalon [Ashkelon], Ekron, Gath and Gaza), which remained unconquered by the Israelites (Josh. xiii 2 *seq*, Judges iii. 3; contrast Josh. xv. 45–47, xix. 43). The institution of the Hebrew monarchy (*c.* 1025 B C.) follows upon periods of Philistine oppression (Judges iii. 31, x. 7, 11, xiii. 1, 5; *see* SAMSON; ELI; SAMUEL; SAUL; DAVID). Their subjugation is ascribed to Samuel (1 Sam. vii. 13), Saul (xiv 47), and David (2 Sam. viii. 1). They evidently recovered their independence, and twice within a short time the northern Israelites laid siege to the border fortress of Gibbethon (1 Ki. xv. 27, xvi. 15). The interrelations of the south Palestinian peoples follows from the unchangeable geographical conditions, and Judah always depended upon its relations with the Philistines on the west and with the Edomites and Arabian tribes on the south-east. "Philistia," with Edom and Beth-Omri (*i e* , the Israelite kingdom), paid tribute to the Assyrian king, Adad-Nirari III. (*c.* 802 B C). The omission of Judah is noteworthy. In the later Assyrian period Philistia was mixed up in pro- and anti-Assyrian intrigues, and suffered from Tiglath-pileser (734), Sargon (720) and Sennacherib (700). In the 7th century Gaza, Ascalon, Ashdod and Ekron were Assyrian vassals, together with Judah, Moab and Edom—in all, 22 kings of the "Hittites" Herodotus mentions the Scythian invasion and sack of the temple of Aphrodite Urania (Astarte) at Ascalon, also the prolonged siege of Ashdod by Psammetichus, and the occupation of Kadytis (? Gaza) by Necho. But the Babylonian empire followed upon traditional lines and thrust back Egypt, and Nabonidus (553 B C) claims his vassals as far as Gaza The Persians took over the realm of their predecessors, and Gaza grew in importance as a seat of international commerce Nehemiah speaks not of Philistines, but of Ashdodites (iv. 7), speaking an "Ashdodite" dialect (xiii 24); just as Strabo regards the Jews, the Idumaeans, the Gazans and the Ashdodites as four cognate peoples having the common characteristic of combining agriculture with commerce. In southern Philistia, at least, Arabian immigration became more pronounced. In the time of Cambyses Arabs were settled at Jenysos south of Gaza (Herod. iii. 5), and when Alexander marched upon Egypt, Gaza with its army of Arabs and Persians offered a strenuous resistance. On the history of the district *see* further GAZA; JEWS; MACCABEES; PALESTINE.

Traditions of the Philistines.—The Philistines were prominent in popular tradition, and the story of Isaac and the Philistine Abimelech (Gen. xxvi., *cf.* xxi. 32) is of great interest for its unbiased picture of enmity, alliance and covenant. But a parallel story (xx.) is without this *Philistine* background Similarly,

one account of the Israelite invasion conceived a conquest of earlier giant inhabitants (Anāḳīm), who survived in Gaza, Gath and Ashdod (Josh. xi. 21 *seq.*, contrast xiii. 3), but were driven out from Hebron by Caleb (Josh. xv. 14, *cf.* Num. xiii. 22, 28). The Philistines themselves are called the remnant of the Anāḳīm (Jer. xlvii. 5, so the Septuagint), or as Caphtōrīm replace the earlier Avvim (Deut. ii. 23, *see* Josh. xiii. 3). Samuel's great defeat of the Philistines leads to "peace between Israel and the *Amorites*" (1 Sam. vii. 14); and the migration of the Danites is placed after Samson's conflicts with the *Philistines* (Judges xviii. *seq.*), or is due to the pressure of *Amorites* (i. 34). Even in David's fights with the Philistines in Judah, Jerusalem is Jebusite, neighbouring non-Israelite cities are Hivite or Amorite (Josh. ix. 7, 2 Sam. xxi. 2), and his strange adversaries find a close parallel in the semi-mythical sons of Anak (2 Sam. xxi. 16, 18, 20, 22). In another tradition, however, David is on intimate relations with a Philistine king, Achish (or Abimelech, Ps. xxxiv.), *cf.* Isaac, p. 735. Traditions agree that the Israelites had to fight for their freedom, but antagonism between Philistines and Israelites was not persistent.

See further H. R. Hall, *Camb. Anc. Hist.*, iii. ch. xii. (with bibliography); and the articles on "Philistines" in *Reallexikon d. Vorgeschichte* (illustr. by Gallin) and *Ency. Bib.* (G. F. Moore). (S. A. C.)

PHILISTUS, Greek historian of Sicily, was born at Syracuse about the beginning of the Peloponnesian War (432 B.C.). He was a faithful supporter of the elder Dionysius, and commander of the citadel. In 386 he was banished for secretly marrying the tyrant's niece. He commanded the fleet against Dion, but was defeated and put to death (356). He settled at Thurii, but afterwards removed to Adria, where he remained until the death of Dionysius (366). He was then recalled by the younger Dionysius, whom he persuaded to dismiss Plato and Dion. During his stay at Adria, Philistus occupied himself with the composition of his Σικελικά, a history of Sicily in eleven books, down to 363, from which point the work was carried on by Athanas. Cicero (*ad. Q. Fr.* ii. 13) calls him "the miniature Thucydides" (*pusillus Thucydides*).

See Diod. Sic. xiii. 103, xiv. 8, xv. 7, xvi. 11, 16; Plutarch, *Dion.* 11–36; Cicero, *Brutus*, 17, *De oratore*, ii. 13; Quintilian, *Instit.* x. 1, 74; fragments and life in C. W. Müller, *Fragmenta historicorum graecorum*, vol. i. (1841); C. Wachsmuth, *Einleitung in das Studium der alten Geschichte* (1895); E. A. Freeman, *History of Sicily* (1891–94); A. Holm, *Geschichte Siciliens im Altert.* (1870–98).

PHILLIMORE, SIR ROBERT JOSEPH (1810–85), English judge, was born at Whitehall on Nov. 5, 1810. Educated at Westminster and Christ Church, Oxford, where a lifelong friendship with W. E. Gladstone began, his first appointment was to a clerkship in the board of control, where he remained from 1832 to 1835. Admitted as an advocate at Doctors' Commons in 1839, he was called to the bar at the Middle Temple in 1841, and rose very rapidly. He was engaged as counsel in almost every case of importance that came before the admiralty, probate or divorce courts. He was appointed judge of the Cinque Ports in 1855, queen's counsel in 1858, and advocate-general in admiralty in 1862, and succeeded Stephen Lushington as judge of the court of arches five years later. Here his care, patience and courtesy, combined with unusual lucidity of expression, won general respect. He was the last judge of the old court of the lord high admiral; after the Judicature act he continued to sit as judge for the new admiralty, probate and divorce division until 1883. He wrote *Ecclesiastical Law of the Church of England*, a book which still holds its ground, *Commentaries on International Law*, and a translation of Lessing's *Laocoon*.

PHILLIMORE, WALTER GEORGE FRANK PHILLIMORE, 1st BARON (1845–1929), British judge, was born in London on Nov. 21, 1845, the eldest son of Sir Robert Joseph Phillimore, Bart. (*q.v.*). He was educated at Westminster and Christ Church, Oxford, and was called to the Bar in 1868. He was made a judge in 1913, and promoted to the Court of Appeal in 1913. He retired from the bench in 1916, and in 1918 was raised to the peerage. In 1918 he became chairman of the naval prize tribunal. Lord Phillimore was English representative on the commission which sat at The Hague in 1920 to prepare the scheme of a permanent Court of International Justice. He died on March 13, 1929.

Lord Phillimore's publications include *Three Centuries of Treaties of Peace and Their Teaching* (1917); he also revised J. H. Blunt's *Book of Church Law* and several of his father's works.

PHILLIPS, EDWARD (1630–?1696), English author, son of Edward Phillips of the crown office in chancery, and his wife Anne, only sister of John Milton, the poet, was born in Aug. 1630 in the Strand, London. His father died in 1631, and Anne Phillips eventually married her husband's successor in the crown office, Thomas Agar. Edward Phillips and his younger brother, John, were educated by Milton. Edward entered Magdalen Hall, Oxford, in November 1650, but left the university in 1651 to be a bookseller's clerk in London. He was tutor to the son of John Evelyn, 1663 to 1672, and in 1677–79 in the family of Henry Bennet, earl of Arlington. The date of his death is unknown but his last book is dated 1696.

His most important work is *Theatrum poetarum* (1675), a list of the chief poets of all ages and countries, but principally of the English poets, with short critical notes and a prefatory *Discourse of the Poets and Poetry*, which has usually been traced to Milton's hand. He also wrote *A New World in Words, or a General Dictionary* (1658), which went through many editions; a new edition of Baker's *Chronicle*, of which the section on the period from 1650 to 1658 was written by himself from the royalist standpoint; a supplement (1676) to John Speed's *Theatre of Great Britain;* and in 1684 *Enchiridion linguae latinae*, said to have been taken chiefly from notes prepared by Milton. Aubrey states that all Milton's papers came into Phillips's hands, and in 1694 he published a translation of his *Letters of State* with a valuable memoir.

His brother, JOHN PHILLIPS (1631–1706), in 1652 published a Latin reply to the anonymous attack on Milton entitled *Pro Rege et populo anglicano.* He appears to have acted as unofficial secretary to Milton, but he published in 1655 a bitter attack on Puritanism entitled a *Satyr against Hypocrites.* In 1656 he was summoned before the privy council for his share in a book of licentious poems, *Sportive Wit*, which was suppressed by the authorities but almost immediately replaced by a similar collection, *Wit and Drollery.*

An extended, but by no means friendly, account of the brothers is given by Wood, *Athen. oxon.* (ed. Bliss, iv. 764 seq.), where a long list of their works is dealt with. This formed the basis of William Godwin's *Lives of Edward and John Phillips* (1815), with which is reprinted Edward Phillips's *Life of John Milton.*

PHILLIPS, STEPHEN (1868–1915), British poet and dramatist, was born on July 28, 1868, at Somertown near Oxford, the son of the Rev. Stephen Phillips, precentor of Peterborough cathedral. He was educated at Stratford and Peterborough grammar schools, and entered Queen's college, Cambridge; but during his first term at Cambridge, when F. R. Benson's dramatic company visited the town, he joined it, and for six years played various small parts. In 1890 a slender volume of verse was published at Oxford with the title *Primavera*, which contained contributions by him and by his cousin, Laurence Binyon, and others. In 1894 he published *Eremus*, a long poem of loose structure in blank verse of a philosophical complexion. *Poems* (1897) brought him many readers. George Alexander commissioned Phillips to write him a play, the result being *Paolo and Francesca* (1900), produced at the St. James's Theatre in 1901. Other dramas in blank verse followed: *Herod: a Tragedy* (1900), *Ulysses* (1902), *The Sin of David* (1904), and *Nero* (1906). In these plays, three of which were produced by Beerbohm Tree, the poet's avowed aim was to revitalize the method of the Greek drama. *Paolo and Francesca* was the most successful. He died at Deal, Kent, on Dec. 9, 1915.

See a notice by Arthur Symons prefixed to the edition (1927) of his last play, *Harold*, which was first printed in the *Poetry Review*, Jan. and March 1916; also Sir Sidney Colvin in T. Humphrey Ward's *English Poets* (vol. v. 1918).

PHILLIPS, WENDELL (1811–1884), American orator and reformer, was born in Boston on Nov. 29, 1811. His father, John Phillips (1770–1823), a man of wealth and influence, graduated at Harvard college in 1788, and became "town advocate and public prosecutor," and in 1822 first mayor of Boston. Phillips attended the public Latin school, entered Harvard college before he was 16

and graduated in 1831. He graduated at the Harvard law school in 1834, and was admitted to the bar in Boston. He soon came under the influence of the anti-slavery movement, witnessing in 1835 the mobbing, in Boston, of William Lloyd Garrison.

A meeting was held on Dec. 8, 1837, at Faneuil Hall to express the sentiments of the people on the murder of Elijah P. Lovejoy, at Alton (Ill.) for defending his press from a pro-slavery mob. In the course of the meeting a speech was made in opposition to its general current by James T. Austin, attorney-general of the State, who said that Lovejoy had died "as the fool dieth," and compared his murderers to the men who threw the tea into Boston harbour just before the War of Independence. The speech seemed likely to divide the audience, when Wendell Phillips took the platform. "When I heard," he said, "the gentleman lay down principles which placed the murderers of Alton side by side with Otis and Hancock, with Quincy and Adams, I thought these pictured lips (pointing to their portraits) would have broken into voice to rebuke the recreant American, the slanderer of the dead." This appeal not merely determined the sentiment of the meeting; it gave Wendell Phillips his first fame and determined his career.

Although loving his profession, and this especially for the opening it gave in the direction of public life, he lived henceforth the life of an agitator, or, like his father, that of a "public prosecutor." Accepting unhesitatingly the leadership of Garrison, and becoming like him a disunionist, he lived essentially a platform life, interested in a variety of subjects, but first and chiefly an abolitionist. In 1865, however, after the Civil War, he broke with Garrison over the question of discontinuing the Anti-Slavery Society; and from that date until the society was disbanded in 1870, he, instead of Garrison, was its president. Phillips' style of eloquence was direct and brilliant, but eminently self-controlled. He may be said to have introduced the direct and colloquial manner upon the American public platform. His logic, while never obtruded, was rarely at fault, but he loved the flash of the rapier, and was never happier than when he had to face a mob and utterly foil it by sheer superiority in fencing. The two volumes of his speeches, as edited by James Redpath, were fortunately made from verbatim reports, and they wisely enclose in parentheses those indications of favour or dissent from the audience which transformed so many of his speeches into exhibitions of gladiatorial skill. After slavery had fallen Phillips associated himself freely with reformers occupied in other paths. He contended in later years for prohibition, woman suffrage and various penal and administrative reforms. He died in Boston on Feb. 2, 1884.

See his *Speeches, Lectures and Letters* (1892); Lorenzo Sears, *Wendell Phillips, Orator and Agitator* (1909); also George L. Austin, *The Life and Times of Wendell Phillips* (1888); C. E. Russell, *Story of Wendell Phillips: Soldier of the Common Good* (1914); and George Edward Woodbury, *Heart of Man and Other Papers* (1920).

PHILLIPSBURG, a town of Warren county, New Jersey, U.S.A., on the Delaware river, opposite Easton, Pa.; served by the Central of New Jersey, the Lackawanna, the Lehigh and Hudson River, the Lehigh Valley and the Pennsylvania railways. Pop. (1920) 16,923 (86% native white). The city rises from the river bottom to bluffs commanding fine views. It has railroad shops and various other manufacturing industries, making mining and agricultural machinery, silk and many other products. The aggregate output in 1925 was valued at $35,040,492. Phillipsburg was settled about 1750, but it was only a straggling village until the Morris canal was constructed (1825). An iron furnace was established in 1848 and the Central railroad of New Jersey reached the town in 1852. It was incorporated in 1861.

PHILLIPSITE, a mineral of the zeolite group; a hydrated potassium, calcium and aluminium silicate, approximating to $(K_2,Ca)Al_2(SiO_3)_4 \cdot 4H_2O$. It varies somewhat in composition, and a variety ("pseudophillipsite") containing rather less silica has the formula $(K_2,Ca)_2Al_4Si_9O_{18} \cdot 9H_2O$. Crystals are monoclinic, but only complex cruciform twins are known, these being exactly like twins of harmotome (*q.v.*), though the phillipsite crystals are usually smaller and more transparent and glassy. Spherical groups with a radially fibrous structure and bristled with crystals on the surface are not uncommon. The hardness is 4½, and the specific gravity 2·2. The species was named in 1825 after William Phillips; French mineralogists call it christianite (after Christian VIII. of Denmark).

Phillipsite is a mineral of secondary origin, and occurs with other zeolites in the amygdaloidal cavities of basic volcanic rocks; *e.g.*, in the basalt of the Giant's Causeway in Co. Antrim and near Melbourne, Victoria, and in leucitite near Rome; while small crystals of recent formation occur in the masonry of the hot baths at Plombières and Bourbonne-les-Bains, France. Minute spherical aggregates embedded in red clay were dredged by the "Challenger" from the bottom of the central Pacific, where they had been formed by the decomposition of volcanic ash.

PHILLPOTTS, EDEN (1862–), British novelist, poet and dramatist, was born in India on Nov. 4, 1862, and educated at Plymouth. He was a clerk for ten years in the Sun fire insurance office, then studied for the stage, but turned his attention to literature, producing a number of successful novels with a Devonshire setting.

PHILLPOTTS, HENRY (1778–1869), English bishop, was born at Bridgwater on May 6, 1778, and was educated at Gloucester College school and at Corpus Christi college, Oxford. He became a fellow of Magdalen college, Oxford, in 1795, took orders in 1802 and was select university preacher in 1804. For twenty years he was chaplain to Shute Barrington, bishop of Durham. He held in succession important preferments, and was consecrated bishop of Exeter in 1831, holding with the see a residentiary canonry at Durham. In 1819 he had defended the existing poor law and the action of the Government in the "Peterloo massacre." In 1825 he vehemently opposed Catholic emancipation, engaging in a fierce polemic on the subject with Charles Butler (1750–1832). He continued to support the Tory party, even when it passed the Roman Catholic Emancipation Act of 1829. He died on Sept. 18, 1869. "Henry of Exeter," as he was commonly called, had little sympathy with either Evangelicals or Tractarians. The famous Gorham judgment was the outcome of his refusal to institute to the living of Brampford Speke a clergyman George Cornelius Gorham (1787–1857), who had openly disavowed his belief in baptismal regeneration; he denounced the equally famous Tract 90 in his episcopal charge of 1843.

See R. N. Shutte, *The Life of Dr. Phillpotts* (1863).

PHILO, often called PHILO JUDAEUS, Jewish philosopher, appears to have spent his whole life at Alexandria, where he was probably born *c.* 20–10 B.C. His father Alexander was alabarch or arabarch (that is, probably, chief farmer of taxes on the Arabic side of the Nile), from which it may be concluded that the family was influential and wealthy (Jos., *Ant.* xviii. 8, 1). The only event of his life which can be actually dated belongs to A.D. 40, when Philo, then a man of advanced years, went from Alexandria to Rome, to persuade the emperor Gaius to abstain from claiming Divine honour of the Jews Of this embassy Philo has left a full account (*De legatione ad Gaium*).

The Hellenistic Jew.—Philo is the most important representative of Hellenistic Judaism, and his writings give us the clearest view of what this development of Judaism in the diaspora was and aimed at.

Philo appears to have been the greatest of all the Jewish philosophers of the Alexandrian school. On one side he is quite a Greek, on the other quite a Jew. His language is formed on the best classical models, especially Plato. He knows and often cites the great Greek poets, but his chief studies had been in Greek philosophy. His system was eclectic, but the borrowed elements are combined into a new unity with so much originality that he may fairly be regarded as representing a philosophy of his own, which has for its characteristic feature the constant prominence of a fundamental religious idea. Philo's closest affinities are with Plato, the later Pythagoreans and the Stoics. Yet with all this Philo remained a Jew, and a great part of his writings is expressly directed to recommend Judaism to the respect and, if possible, the acceptance of the Greeks. He was not a stranger to the specifically Jewish culture that prevailed in Palestine; in Hebrew he was not proficient, but he had evidently made some study of that language. His method of exegesis is identical in form with that of the Palestinian scribes, and there are coincidences in matter. Philo recog-

nized the Mosaic Scriptures of the Pentateuch as of absolute Divine authority and as containing all truth. The other Jewish Scriptures are also recognized as prophetic, *i.e.*, as the writings of inspired men, but he does not place them on the same lines with the law. Everything that is right and good in the doctrines of the Greek philosophers had already been quite as well, or even better, taught by Moses. Thus, since Philo had been deeply influenced by the teachings of Greek philosophy he actually finds in the Pentateuch everything which he had learned from the Greeks. From these premises he assumes as requiring no proof that the Greek philosophers must in some way have drawn from Moses, a view indeed which is already expressed by Aristobulus. These presuppositions were maintained by an allegorical interpretation of Scripture. With its aid he discovers indications of the profoundest doctrines of philosophy in the simplest stories of the Pentateuch.

His Doctrine of God starts from the idea that God is a Being absolutely bare of quality. All quality in finite beings has limitation, and no limitation can be predicated of God, who is eternal, unchangeable, simple substance, free, self-sufficient, better than the good and the beautiful. To predicate any quality (ποιότης) of God would be to reduce Him to the sphere of finite existence. Of Him we can say only *that* He is, not *what* He is, and such purely negative predications as to His being appear to Philo, as to the later Pythagoreans and the Neoplatonists, the only way of securing His absolute elevation above the world. At bottom, no doubt, the meaning of these negations is that God is the most perfect being; and so, conversely, we are told that God contains all perfection, that He fills and encompasses all things with His being.

A consistent application of Philo's abstract conception of God would exclude the possibility of any active relation of God to the world, and therefore of religion, for a Being absolutely without quality and movement cannot be conceived as actively concerned with the multiplicity of individual things. And so in fact Philo does teach that the absolute perfection, purity and loftiness of God would be violated by direct contact with imperfect, impure and finite things. But the possibility of a connection between God and the world is reached through a distinction which forms the most important point in his theology and cosmology; the proper Being of God is distinguished from the infinite multiplicity of divine Ideas or Forces: God himself is without quality, but He disposes of an infinite variety of Divine Forces, through whose mediation an active relation of God to the world is brought about.

Mediating Forces.—Philo's conception of the nature of these mediating Forces was self-contradictory. On the one hand they are nothing else than Ideas of individual things conceived in the mind of God, and as such ought to have no other reality than that of immanent existence in God, and so Philo says expressly that the totality of Ideas, the *κόσμος νοητός*, is simply the Reason of God as Creator (*θεοῦ λόγος ἤδη κοσμοποιοῦντος*). Yet, on the other hand, they are represented as daemons or angels, hypostases distinct from God, individual entities existing independently and apart from Him. This vacillation, however, as Zeller and others have justly remarked, is necessarily involved in Philo's premises, for, on the one hand, it is God who works in the world through His Ideas, and therefore they must be identical with God; but, on the other hand, God is not to come into direct contact with the world, and therefore the Forces through which He works must be distinct from Him. The same inevitable amphiboly dominates in what is taught as to the supreme Idea or Logos. Philo regards all individual Ideas as comprehended in one highest and most general Idea or Force—the unity of the individual Ideas—which he calls the Logos or Reason of God, and which is again regarded as operative Reason. The Logos, therefore, is the highest mediator between God and the world, the firstborn son of God, the archangel who is the vehicle of all revelation, and the high priest who stands before God on behalf of the world. Through him the world was created, and so he is identified with the creative Word of God in Genesis (the Greek λόγος meaning both "reason" and "word"). Here again, we see, the philosopher is unable to escape from the difficulty that the Logos is at once the immanent Reason of God, and yet also an hypostasis standing between God and the world. The whole doctrine of this mediatorial hypostasis is a strange intertwining of very dissimilar threads; on one side the way was prepared for it by the older Jewish distinction between the Wisdom of God and God Himself, of which we find the beginnings even in the Old Testament (Job xxviii. 12 *seq.;* Prov. viii., ix.), and the fuller development in the books of Ecclesiasticus and Wisdom, the latter of which comes very near to Philo's ideas if we substitute for the term "wisdom" that of (divine) "Reason." In Greek philosophy, again, Philo, as we have seen, chiefly follows the Platonic doctrines of Ideas and the Soul of the World, and the Stoic doctrine of God as the λόγος or Reason operative in the world. In its Stoic form the latter doctrine was pantheistic, but Philo could adapt it to his purpose simply by drawing a sharper distinction between the Logos and the world.

The World and Creation, in Philo's doctrine, rest on the presupposition of an absolute metaphysical contrast between God and the world. The world can be ascribed to God only in so far as it is a cosmos or orderly world; its material substratum is not even indirectly referable to God. Matter (ὕλη, or, as the Stoics said, *οὐσία*) is a second principle, but in itself an empty one, its essence being a mere negation of all true being. It is a lifeless, unmoved, shapeless mass, out of which God formed the actual world by means of the Logos and divine Forces. Strictly, the world is only formed, not created, since matter did not originate with God.

Philo's Doctrine of Man is also strictly dualistic, and is mainly derived from Plato. Man is a twofold being, with a higher and a lower origin. Of the pure souls which fill airy space, those nearest the earth are attracted by the sensible and descend into sensible bodies; these souls are the Godward side of man. But on his other side man is a creature of sense, and so has in him a fountain of sin and all evil. The body, therefore, is a prison, a coffin, or a grave for the soul which seeks to rise again to God. The highest maxim of Philo's ethics is therefore deliverance from the world of sense and the mortification of all the impulses of sense. In carrying out this thought, Philo differs from the Stoics. The Stoics cast man upon his own resources; Philo points him to the assistance of God, without whom man, a captive to sense, could never rise to true wisdom and virtue. Even in this life the truly wise and virtuous is lifted above his sensible existence, and enjoys in ecstasy the vision of God, his own consciousness sinking and disappearing in the Divine light. Beyond this ecstasy there lies but one further step, viz., entire liberation from the body of sense and the return of the soul to its original condition; it came from God and must rise to Him again. But natural death brings this consummation only to those who, while they lived on earth, kept themselves free from attachment to the things of sense; all others must at death pass into another body; transmigration of souls is in fact the necessary consequence of Philo's premises.

Works.—The titles of the numerous extant writings of Philo present at first sight a most confusing multiplicity. More than three-fourths of them, however, are really mere sections of a small number of larger works. Three such great works on the Pentateuch can be distinguished.

I. The smallest of these is the Ζητήματα καὶ λύσεις (*Quaestiones et solutiones*), a short exposition of Genesis and Exodus, in the form of question and answer. The work is cited under this title by Eusebius (*H.E.* iii. 18, 1, 5; *Praep. Ev.* vii. 13), and by later writers, but the Greek text is now almost wholly lost, and only about one-half preserved in an Armenian translation. Genesis seems to have occupied six books. Eusebius tells us that Exodus filled five books. In the Armenian translation, first published by the learned Mechitarist, J. Bapt. Aucher, in 1826, are preserved four books on Genesis and two on Exodus, but with lacunae. A Latin fragment, about half of the fourth book on Genesis (*Phil. Jud. CII. quaestt. . . . super Gen.*), was first printed at Paris in 1520. Of the Greek we have numerous but short fragments in various Florilegia. The interpretations in this work are partly literal and partly allegorical.

II. Philo's most important work is the Νόμων ἱερῶν ἀλληγορίαι (Euseb. *H.E.* ii. 18, 1; Phot. *Bibl.* Cod. 103), a vast and copious allegorical commentary on Genesis, dealing with chaps. ii.–iv., verse by verse, and with select passages in the later chapters. The readers in view are mainly Jews, for the form is modelled on the

rabbinic Midrash. The main idea is that the characters which appear in Genesis are properly allegories of states of the soul (τρόποι τῆς ψυχῆς). All persons and actions being interpreted in this sense, the work as a whole is a very extensive body of psychology and ethics. It begins with Gen. ii. 1, for the *De mundi opificio*, which treats of the creation according to Gen. i., ii., does not belong to this series of allegorical commentaries, but deals with the actual history of creation, and that under a quite different literary form. With this exception, however, the Νόμων ἀλληγορίαι includes all the treatises in the first volume of Mangey's edition.

III. A work of a very different kind is the group of writings which we may call "An Exposition of the Mosaic Law for Gentiles," which, in spite of their very various contents, present on nearer examination indubitable marks of close connection. In them Philo seeks to give an orderly view of the chief points of the Mosaic legislation in the Pentateuch, and to recommend it as valuable to Gentile readers. The method of exposition is somewhat more popular than in the allegorical commentaries, for, though that method of interpretation is not wholly excluded, the main object is to give such a view of the legislation as Philo accepted as historical. This work has three main divisions: (*a*) an Account of the creation (κοσμοποιΐα) which Moses put first to show that his legislation was conformed to the will of nature, and that therefore those who followed it were true cosmopolitans; (*b*) the Biographies of the Virtuous—being, so to speak, the living unwritten laws which, unlike written laws, present the general types of moral conduct; (*c*) Legislation Proper, in two subdivisions—(α) the ten principal chapters of the law, (β) the special laws belonging to each of these ten. An appendix adds a view of such laws as do not fall under the rubrics of the decalogue.

IV. Besides the above-named three great works on the Pentateuch, Philo was the author of a number of isolated writings, of which the following have reached us either in their entirety or in fragments. (1) Περὶ βίου Μωσέως (*Vita Mosis*, lib. i.–iii., M. ii. 80–179). (2) Περὶ τοῦ πάντα σπουδαῖον εἶναι ἐλεύθερον (*Quod omnis probus liber*, M. ii. 445–470). The genuineness of the writing now possessed by us is not undisputed: but *see* Lucius, *Der Essenismus* (1881), pp. 13–23. (3) Εἰς Φλάκκον (*Adversus Flaccum*, M. ii. 517–544) and (4) Περὶ ἀρετῶν καὶ πρεσβείας πρὸς Γάϊον (*De legatione ad Gaium*, M. ii. 545–600). These two works have a very intimate connection. In the first Philo relates how the Roman governor, Flaccus, in Alexandria, towards the beginning of the reign of Caligula, allowed the Alexandrian mob to persecute the Jews. In the second he relates the persecution under Caligula that divine honours should be everywhere accorded to him, and how the Jews of Alexandria in vain sought relief by a mission to Rome which was headed by Philo. These were parts of a larger work, in five books. (5) Περὶ προνοίας (*De providentia*). This work has reached us only in an Armenian translation, which has been edited, with a Latin translation, by Aucher (*see* below), 1822. It is mentioned by its Greek title in Eusebius (*H.E.* ii. 18, 6; *Praep. Ev.* vii. 20 fin., viii. 13 fin., ed. Gaisford). (6) Ἀλέξανδρος ἢ περὶ τοῦ λόγον ἔχειν τὰ ἄλογα ζῶα (*De Alexandro et quod propriam rationem muta animalia habeant;* so Jerome, *De Vir. Ill.* c. 11); the Greek title is given in Euseb. *H.E.* ii. 18, 6. This also now exists only in an Armenian translation, which has been edited by Aucher. Two small Greek fragments occur in the *Florilegium* of Leontius and Johannes (Mai, *Scr. vet. nov. coll.* vii. 1, pp. 99, 100a). (7) Ὑποθετικά, a writing now known to us only through fragments preserved in Euseb., *Praep. Ev.* viii. 6, 7. (8) Περὶ Ἰουδαίων, a title met with in Euseb. *H.E.* ii. 18, 6. The writing is no doubt the same as Ἡ ὑπὲρ Ἰουδαίων ἀπολογία, from which a quotation is given in Euseb. *Praep. Ev.* viii. 11. To this place also, perhaps, belongs the *De nobilitate* (M. ii. 437–444), which treats of that true noblesse of wisdom which the Jewish people does not lack.

V. *The doubtful treatises:* (1) Περὶ βίου θεωρητικοῦ ἢ ἱκετῶν ἀρετῶν (*De vita contemplativa*); the sole original account of an ascetic community known as the Therapeutae (*q.v.*) having their home on the shores of Lake Mareotis. (2) Περὶ ἀφθαρσίας κόσμου (*De incorruptibilitate mundi*), declared unauthentic by Z. Frankel and J. Bernays, has been defended by F. Cumont. (3) Περὶ κόσμου (*De mundo*). It is generally agreed that, in L. Cohn's words, this is "nothing but a compilation from various portions of the περὶ ἀφθαρσίας κόσμου and other Philonic works." (4) Two discourses, *De Sampsone* and *De Iona*, extant only in Armenian, are unauthentic. (5) Περὶ το πάντα σπουδαῖον εἶναι ἐλεύθερον (*Quod omnis probus liber sit*) may be an early work of Philo, which P. Wendland believes to be the case. (6) Περὶ προνοίας (*De providentia*), which we possess as a whole only in an Armenian version, consists of two books, the first of which appears to be in a Christian recension, but there is no reason for denying its Philonic origin.

PHILOCTETES, son of Poeas king of the Malians of Mt. Oeta, a celebrated hero of the Trojan War. Homer merely states that he was distinguished for his prowess with the bow; that he was bitten by a snake on the journey to Troy and left behind in the island of Lemnos; and that he subsequently returned home in safety. In the post-Homeric accounts, Philoctetes or his father had been given the bow and arrows of Heracles (*see* HERCULES) as a reward for kindling the fire on Mt. Oeta, on which the hero immolated himself. Philoctetes remained at Lemnos till the tenth year of the war. An oracle having declared that Troy could not be taken without the arrows of Heracles, Odysseus and Diomedes (or Neoptolemus) were sent to fetch Philoctetes. On his arrival before Troy he was healed of his wound by Machaon, and slew Paris; shortly afterwards the city was taken. On his return to his own country, finding that a revolt had broken out against him, he again took ship and sailed for Italy, where he founded Petilia and Cremissa. He fell fighting on the side of a band of Rhodian colonists against some later immigrants from Pallene in Achaea. His tomb and sanctuary were shown at Macalla, on the coast of Bruttium.

PHILODEMUS, Epicurean philosopher and poet, was born at Gadara in Coele-Syria early in the 1st century B.C., and settled in Rome in the time of Cicero. He was a friend of Calpurnius Piso, and was implicated in his profligacy by Cicero (*in Pisonem*, 29), who, however, praises him warmly for his philosophic views and for the *elegans lascivia* of his poems (*cf.* Horace, *Satires*, 1. 2. 120). The Greek anthology contains thirty-four of his epigrams. Thirty-six treatises attributed to Philodemus were recovered from a villa at Herculaneum.

The *Rhetoric* has been edited by Sudhaus (1892–95); the *De Ira* and the *De Pietate* by Gomperz (1864–65); the *De Musica* by Kempke (1884); *De Vitiis* by Ussing (1868); *De Morte* by Mekler (1886). See *Hercul. Volum.* (Oxford, 1824 and 1861); Mayor on Cicero's *De Natura deorum* (1871); Überweg, *Grundriss der Gesch. der Philosophie*, Bd. I. (1926).

PHILOLAUS (b. *c.* 480), Greek philosopher of the Pythagorean school, born at Tarentum or at Crotona (so Diog. Laërt. viii. 84), was probably a teacher of Democritus. After the death of Pythagoras great dissensions prevailed in the cities of lower Italy. According to some accounts, Philolaus, obliged to flee, took refuge first in Lucania and then at Thebes, where he had as pupils Simmias and Cebes, who subsequently, being still young men, were present at the death of Socrates. Before this Philolaus had returned to Italy, where he was the teacher of

Archytas. He entered deeply into the Pythagorean number theory, particularly dwelling on the properties inherent in the decad—the sum of the first four numbers, consequently the fourth triangular number, the *tetractys* (see *Vit. Pythag.* ap. *Phot. Bibl.* p. 712)—which he called great, all-powerful, and all-producing. The great Pythagorean oath was taken by the sacred *tetractys.* The discovery of the regular solids is attributed to Pythagoras by Eudemus, and Empedocles is stated to have been the first who maintained that there are four elements. Philolaus, connecting these ideas, held that the elementary nature of bodies depends on their form, and assigned the tetrahedron to fire, the octahedron to air, the icosahedron to water, and the cube to earth; the dodecahedron he assigned to a fifth element, aether, or, as some think, to the universe (*see* Plut. *de Pl. Ph.* ii. 6, *ἐκ δὲ τοῦ δωδεκαέδρου τὴν τοῦ παντὸς σφαῖραν* and Stob. *Ecl. Phys.* i. 10, *ὁ τᾶς σφαίρας ὁλκός*). This theory, however superficial from the standpoint of observation, indicates considerable knowledge of geometry and gave a great impulse to its study. Following Parmenides, Philolaus regarded the soul as a "mixture and harmony" of the bodily parts; he also assumed a substantial soul, whose existence in the body is an exile on account of sin.

Philolaus was the first to propound the doctrine of the motion of the earth; some attribute this doctrine to Pythagoras, but there is no evidence in support of their view. Philolaus supposed that the sphere of the fixed stars, the five planets, the sun, moon and earth, all moved round the central fire, which he called the hearth of the universe, the house of Zeus, and the mother of the gods (*see* Stob. *Ecl. Phys.* i. 488); but as these made up only nine revolving bodies he conceived, in accordance with his number theory, a tenth, which he called counter-earth, *ἀντίχθων*. He supposed the sun to be a disk of glass which reflects the light of the universe. He made the lunar month consist of 29½ days, the lunar year of 354, and the solar year of 365½ days. He was the first who published a book on the Pythagorean doctrines, a treatise used by Plato in the composition of his Timaeus and to which the mystical name Βάκχαι is sometimes given.

PHILOLOGICAL ARTICLES. In addition to the general article PHILOLOGY and an outline of the ramifications of Comparative Philology, the subject of GRAMMAR is exhaustively treated. All the main languages of the world have articles of their own, *e.g.,* ARABIC LANGUAGE; CHINESE LANGUAGE; ENGLISH LANGUAGE; FRENCH LANGUAGE; GERMAN LANGUAGE; GREEK LANGUAGE, ANCIENT and GREEK LANGUAGE, MODERN; HEBREW LANGUAGE; ITALIAN LANGUAGE; JAPANESE LANGUAGE; LATIN LANGUAGE; MANCHU LANGUAGE; MONGOLIAN LANGUAGE; POLYNESIAN LANGUAGES; RUSSIAN LANGUAGE; SERBO-CROAT LANGUAGE; SPANISH LANGUAGE; TURKISH LANGUAGE. This is by no means an exhaustive list as many little-known languages are included, *e.g.,* BUSHMAN LANGUAGES. In the event of a language not receiving discussion under its own name it may be discovered under the name of the family to which it belongs, *e.g.,* INDO-EUROPEAN LANGUAGES; CELTIC LANGUAGES; TIBETO-BURMAN LANGUAGES; etc. There is an article on PHONETICS and another on PRONUNCIATION.

PHILOLOGY. The word philology is here taken as meaning the science of language, *i.e.,* the study of the structure and development of languages, thus corresponding to linguistics (Fr. *linguistique* and Ger. *Sprachwissenschaft*), but differing from philology, as it is generally understood on the Continent and sometimes in England where it means literary or classical scholarship; to the philologist in the latter sense language is one of the means to the comprehension of the whole culture of some nation, but not an object of study for its own sake, as it is to the philologist in the sense in which the word is here used. Though there has been, and still here and there may be, some antagonism between the two lines of study, they cannot properly be separated without an injurious onesidedness, as language is closely bound up with the development and expression of the whole cultural life of any nation or race.

Before A.D. 1800.—Though languages were studied in a scientific spirit for many centuries, it is not till the beginning of the 19th century that we see the rise of philology as it is now understood, with the chief stress laid on comparison of related languages and the historical development of their structures.

The Chinese had, centuries before our era, elaborate dictionaries of their own language. Similarly the Assyrians compiled lists of words and syllables with grammatical explanations. But they did not penetrate so deeply into the understanding and analysis of their own language as did the early Indians, whose grammatical investigations have had a far-reaching influence on European philology, especially in the 19th century. It was occupation with the sacred hymns and notably the *Rigveda* that gave the chief impulse to the study: each little detail was handed down with religious fidelity and was therefore carefully examined. We find in India painstaking investigations into phonetics with a minute description of each sound and its formation; further, precise accounts of the changes of sounds in the inflection and formation of words. What was studied was not only the rôle of sounds in isolated words, but also the modification which sounds underwent when words were pronounced in connected speech (*sandhi*). Each word was analysed into its elements: root, affixes to form stems, and inflectional endings, and statistics were given of the occurrence of each of these elements. In this way the earliest contributions were given to the building up of an etymological science. Among the Indian grammarians Pāṇini ranks first; his work has been called "the most complete grammar existing for any language, dead or living."

In Greece philosophers discussed the ultimate origin of language, some holding that words had come into existence by nature, others that they were due to convention. Incidentally they indulged in the wildest etymological guesses. Aristotle gives the first beginnings of a division into parts of speech, and this was further developed by the Stoics, to whom are due those names of the different cases which in their Latin translations are still in use with us. The Alexandrians are of importance through their scholarly treatment of the old classical literature. But the horizon was bounded: no "barbarous" tongue was thought worthy of study, and therefore no true insight into the essence of language could be gained. Roman grammarians did very little beyond imitating their Greek predecessors. Nor did the middle ages produce anything worthy of mention in this brief survey.

From the 16th century onwards we find a growing number of descriptions of single languages, but very little was done for a comparative investigation of languages, except perhaps for the Semitic family. The foolish superstition, however, that all languages descended from Hebrew as the language spoken in the garden of Eden, gave rise to many absurd etymologies. Leibniz was one of the first to entertain saner ideas with regard to the division of languages according to their relationship; like some of his contemporaries he was also interested in the idea of a universal language for scientific purposes. Among valuable works of the 18th century we shall here mention only the comprehensive, but uncritical collections of words and specimens from all the then known languages; the best of them are due to Pallas (1786, 1791) and to Hervas y Panduro (1784, 1800–05); these were superseded by Adelung's *Mithridates* (1806–17). D. Jenisch's *Philosophisch-kritische Vergleichung . . . von vierzehn Sprachen Europens* (1796) is a comparative appraisement of languages chiefly from an aesthetic point of view and thus totally different from what we now understand by comparative philology.

Rise of Comparative Philology.—The discovery of Sanskrit gave a mighty impulse to linguistic studies, though the work of the French Jesuit missionary Coerdoux (1767) with its comparison of Sanskrit with Latin was not printed till 40 years later. More importance was attached at the time to Sir William Jones's often quoted words (1796) in which he drew the conclusion from the grammatical structure of Sanskrit, Greek and Latin that they

had "sprung from some common source, which perhaps no longer exists." This paved the way for the recognition of the great Aryan or Indo-European family of languages, and in 1799 Gyármathi proved that Magyar (Hungarian) was related to Finnic and thus laid the foundation of Finno-Ugric philology.

In the beginning of the 19th century these sporadic hints were worked up in a more systematic way. The chief impulses came about the same time from three men of genius, the Dane, Rasmus Rask, and the two Germans, Franz Bopp and Jacob Grimm. Rask saw the importance of sound laws and formulated the Germanic consonant shift before Grimm; he classified not only Aryan, but also Finno-Ugric and Dravidian languages and gave an excellent exposition of the methodological principles of the new science Bopp started from Sanskrit, but successively submitted a greater and greater number of the Aryan languages to penetrating study and wrote the first comprehensive comparative grammar of all these languages—a work which exercised an enormous influence on linguistic studies all over Europe. Grimm was chiefly occupied with the Germanic group and brought out a very important grammar of all the languages of that group with the main stress laid on historic development. Bopp and Grimm had a great number of followers, chiefly in Germany—of the elder generation only one scholar can be mentioned here. Pott, whose etymological investigations cleared much new ground Chairs of comparative philology were founded in many universities, and periodicals were devoted to the science, the most important for a long time being Kuhn's *Zeitschrift für vergleichende Sprachforschung* The new points of view (comparative and historical) soon affected all branches of linguistics, and a number of special "philologies" came into existence with similar objects and methods, Romanic philology headed by Diez, Slavic by Schleicher and Miklosich, Keltic by Zeuss. For the classical languages Georg Curtius's researches were of very great importance

The chief leader in Aryan philology about 1860 was August Schleicher, whose *Compendium der vergleichenden Grammatik* (1st ed 1861) had far-reaching influence, especially through its insistence on regularity of sound-changes and through its bold attempts at reconstructing theoretical forms of primitive Aryan, which he took as the starting points for his explanations of forms actually existing But the system was too rigid and rectilinear to do justice to the complexity of linguistic life; the whole was vitiated by the dogmatic assumption that primitive Aryan had a very simple structure with only three vowels (*i, a, u*), and that the whole evolution had taken place in prehistoric times through three periods, a root-period, a period of agglutination, and finally one of inflection, while the historic period had witnessed only decay.

New Views.—A new era may be dated from about 1875, when a series of important discoveries profoundly modified the views of scholars about the primitive structure of our family of languages The way had to some extent been paved through the sober discussions of the nature of language in general found in the works of J N Madvig and W. D. Whitney; of still greater importance was the study of phonetics, which now came to be more generally recognized as the necessary basis of all linguistic investigation. The study of the complicated phonetic systems of living languages shattered the belief in the extreme simplicity of primitive Aryan The realization of the extremely important part played by analogy formations in the evolution of modern languages led to a wider application of the principle of analogy to the explanation of forms in the older stages. Thus a great many seemingly exceptional forms were explained in a natural way; and a new school of comparativists triumphantly proclaimed that phonetic laws admitted of no exceptions; sound laws and analogy sufficed between them to account for the historic development of forms.

The most important discovery of that period was the "palatal law," by which certain consonantal peculiarities were used to prove that Sanskrit in prehistoric times had had a vocalic system similar to that of Greek, with *e* and *o* in definite cases where Sanskrit as we know it has uniformly *a*. The belief in the absolute primitivity of Sanskrit, which had been a dogma in the first period, could thus be maintained no longer, and some features of European languages, which had been supposed to be later developments, were now seen to be remnants of the oldest accessible form of the Aryan languages. The theory of the vowel alternation found, for instance, in Greek λείπω, λέλοιπα, ἔλιπον and still surviving in English *drink, drank, drunk* (*ablaut*, gradation or apophony) was completely reversed, the grade *lip* being now considered a weakening of *leip*, instead of being taken as the original stage, of which *leip* was an expansion Karl Verner discovered the astonishing fact that differences in Germanic consonants, like that between German *t* in *Vater* and *d* in *Bruder*, found their explanation in primeval accent-conditions preserved in their oldest form in Sanskrit only, and that the difference between *s* in English *was* and *r* in *were* was connected with the fact that the singulars of perfect tenses in Sanskrit are stressed on the root, but plurals on the ending. All this opened new vistas and gave fresh impulses to Aryan philology. A codification of Aryan grammar according to the new views was given in Brugmann's *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen* (2nd ed. 1897–1916), while the theoretical basis was worked out in H. Paul's *Prinzipien der Sprachgeschichte* (4th ed. 1909) and B Delbruck's *Einleitung in das Sprachstudium* (5th ed. 1908), Delbruck also wrote the first comprehensive Aryan syntax (*Vergleichende Syntax der indogermanischen Sprachen*, 1893–1900).

Aryan Languages.—For several decades there had been no doubt as to what languages were Aryan, and the relation to it even of Albanian and Armenian had now been settled. But the 20th century has brought the discovery of new languages belonging at any rate peripherically to the Aryan family, namely Tokharian (really two different languages) and one of the Hittite languages. These present several features not paralleled in the other Aryan languages and not yet sufficiently cleared up in spite of the keen interest and labours of several scholars. Attempts have also been made to demonstrate a more remote affinity between the Aryan and two other great families of languages. that with the Finno-Ugric family seems highly probable.

A most interesting attempt has recently been made to prove a primitive relationship between Aryan and Sumerian (C. Autran, *Sumérien et Indo-Européen*, Paris, 1925). Some of the similarities adduced are very striking, but there are so many difficulties in the grammatical structure of the two languages that the kinship must at present be considered an open question.

Outside the Aryan languages much excellent work has been done, especially since the methods developed in Aryan philology have penetrated into the other domains. In many of them historical research is made impossible by the fact that we have only recent texts and descriptions; but sometimes the co-existence of several related languages permit us to some extent to draw conclusions backwards to a state in which the now separate languages formed one whole. thus with regard to primitive Bantu ("Ur-Bantu"). Some languages found in old inscriptions have baffled all attempts at comprehension, among them Etruscan.

Language and Racial Psychology.—While most of those who have dealt with the general problems of the nature of language and its development have started, as was natural, from the European languages and the great family of languages to which they belong, there have been other scholars whose endeavours have been especially directed towards the understanding of the psychology of language and who have therefore to a great extent gone outside the languages spoken by civilized nations to ascertain relations between the language of a race and its culture and mental characteristics. A pioneer in that direction was Wilhelm v. Humboldt, whose great work on the Kawi language was prefaced by a profound investigation into the differences in structure of the various human languages and their influence on the mental development of man (1836–40). His chief disciple was H Steinthal, who in numerous works treated of the relation between language, logic and psychology. His best work, *Charakteristik der hauptsächlichsten Typen des Sprachbaues* (1860), was completely remodelled in 1893 by F Misteli and in this shape is still a most useful survey of the grammatical structure of

some of the most outstanding languages with psychological interpretation. Excellent work was done in the same direction by H. C. von der Gabelentz and his son Georg, both of them possessing wide linguistic knowledge and psychological acumen. A small, but very valuable work is F. N. Finck, *Die Haupttypen des Sprachbaus* (Leipzig, 1910), with its analysis of eight select linguistic structures on the basis of one text from each language.

In 1900 the well-known German philosopher W. Wundt, employing the whole apparatus of modern psychologists and part of that of linguists, made an attempt to present a consistent comprehensive survey of linguistic phenomena (*Völkerpsychologie, I. Die Sprache*), but his views met with little acceptance on the part either of philologists (Delbrück, Sütterlin) or of philosophers (Marty). A recent school in Germany, headed by K. Vossler, tries to connect grammar with the state of civilization in general and of literature in particular, interpreting linguistic developments and grammatical peculiarities in terms of national psychology.

The psychological aspect and the emotional importance of language in general has been studied recently with great ardour. Among those who have lately contributed to this side of philology are: F. Mauthner, A. Marty, Ch. Bally, E. Cassirer, J. van Ginneken and H. Delacroix.

Language and History.—Linguistic research has very often been invoked to assist in settling historical questions. Important results have been arrived at through investigation of place-names (*q.v.*). The history of a nation's culture can be illustrated through a study of successive strata of loan-words. (*See* LANGUAGE.) The question of the Scandinavian origin of the Russian empire has been definitely settled through the names in the oldest sources. It is now possible to speak of linguistic archaeology as a separate branch of science, *see* especially such important works as V. Hehn, *Kulturpflanzen und Haustiere* (6th ed., Berlin, 1894); O. Schrader, *Sprachvergleichung und Urgeschichte* (3rd ed., Jena, 1906); O. Schrader, *Reallexikon der indogermanischen Altertumskunde* (2nd ed. 1917); J. Hoops, *Waldbäume und Kulturpflanzen im germanischen Altertum* (Strasbourg, 1905); S. Feist, *Kultur, Ausbreitung und Herkunft der Indogermanen* (1913).

Languages of the World.—A survey of all the known languages of the inhabited earth with short grammatical sketches and brief specimens was given in Friedrich Müller's *Grundriss der Sprachwissenschaft* (4 vols., Wien, 1876–88). The attempt has never been renewed on so extensive a scale. F. N. Finck, *Die Sprachstämme des Erdkreises* (Leipzig, 1909), gives a bare enumeration of the names of languages, but the great work *Les Langues du Monde* by A. Meillet et Marcel Cohen (Paris, 1924) does not content itself with this, but gives valuable discussions on many problems connected with the present state of linguistic science with regard to some, at least, of the linguistic groups. An extremely bold attempt at proving relationship between all existing languages and thus establishing the monogenesis of human language is found in various works by A. Trombetti, most elaborately in *Elementi di Glottologia* (Bologna, 1923); most philologists prefer not to commit themselves either to this theory or definitely to the opposite theory of polygenesis, but to leave the question open as impossible of solution at present. An equally bold attempt is made in the recent book by Father W. Schmidt, *Die Sprachfamilien und Sprachenkreise der Erde* (Heidelberg, 1926): he tries to group all known languages genetically and then to show intimate connection between a series of phenomena—phonetic traits, such as the distinction between voiced and voiceless consonants, initial and final sounds and sound-groups, morphological peculiarities (number, exclusive and inclusive pronouns, gender, numeral systems), syntactical features (place of genitive and adjective)—on the one hand and on the other hand ancient centres and migrations of cultural phenomena: totemism, agriculture, matriarchy, etc.

Streitberg, *Die Erforschung der indogermanischen Sprachen* (only two volumes of a planned great work have appeared, dealing with Greek, Latin, Keltic, Slavic and Albanian, 1916–17); *Stand und Aufgaben der Sprachwissenschaft, Festschrift für W. Streitberg* (1924); H. Pedersen, *Sprogvidenskaben i det 19. Aarhundrede* (1924); V. Thomsen, *Geschichte der Sprachwissenschaft* (1927).

For general bibliography *see* the two works mentioned above, *Les Langues du Monde*, and W. Schmidt, *Die Sprachfamilien. See* also under LANGUAGE and GRAMMAR. (O. J.)

PHILO OF BYZANTIUM, Greek writer on mechanics, flourished during the latter half of the 2nd century B.C. (according to some, a century earlier). He was the author of a large work (Μηχανική σύνταξις), of which considerable portions remain.

See ed. by R. Schöne (1893), and W. Schmidt *De Ingeniis Spiritualibus* (Latin tr. of Arabic version of a lost original, 1899).

PHILO OF LARISSA, Greek philosopher of the first half of the 1st century B.C. During the Mithridatic wars he left Athens and took up his residence in Rome. He was a pupil of Clitomachus, whom he succeeded as head of the Third or New Academy. According to Sextus Empiricus, he was the founder of the Fourth Academy, but other writers refuse to admit the separate existence of more than three academies (*see* ACADEMY, GREEK). In Rome he lectured on rhetoric and philosophy, and collected many eminent pupils, amongst whom Cicero was the most famous.

See Grysar, *Die Akademiker Philo und Antiochus* (1849); Hermann, *De Philone Larissaeo* (Göttingen, 1851 and 1855); and Überweg, *Grundriss der Gesch. der Philosophie*, Bd. I. (1926).

PHILOPATRIS, the title of a dialogue formerly attributed to Lucian, but now generally admitted to be spurious. The scene is laid at Constantinople. A certain Triephon, who has been converted to Christianity by a bald, long-nosed Galilaean, who was carried up through the air into the third heaven (an evident allusion to St. Paul), meets a friend, Critias, who is in a state of great excitement. Triephon inquires the reason, and the invocation of Zeus by Critias leads to a discussion on paganism and Christianity, in which all the gods proposed by Critias are rejected by Triephon, who finally suggests that Critias should swear by the Trinity. Critias goes on to relate how he had been introduced to a gathering of pessimists, who predicted all kinds of disturbances in the empire and defeat at the hands of its enemies. The *Philopatris* was for a long time regarded as an attack upon Christianity, and assigned to the time of Julian the Apostate (emperor 361–363). Chronological indications led Niebuhr to ascribe it to the reign of Nicephorus Phocas (963–969), a view now generally supported.

PHILOPOEMEN (253–184 B.C.), Greek general, was born at Megalopolis, and educated by the academic philosophers Ecdemus and Demophanes or Megalophanes. In 233–2 Philopoemen skilfully evacuated Megalopolis before the attack of Cleomenes III., and distinguished himself at Sellasia (222). The next eleven years he spent as a condottiere in Crete. Elected commander of the League's cavalry on his return, he reorganized that force and defeated the Aetolians on the Elean frontier (210). Appointed to the chief command two years later, he introduced heavy armour and close formation for the infantry, and with a well-trained army beat Machanidas of Sparta, near Mantinea. The new "liberator" was now so famous that Philip V. of Macedon attempted to poison him. In 202–1 Philopoemen drove Nabis, the Spartan tyrant, from Messene and routed him off Tegea. After another long sojourn in Crete he again received the command against Nabis. Though unsuccessful at sea, he almost annihilated Nabis's land force near Gythium, but was prevented by the Roman Flamininus from taking Sparta. In 190 Philopoemen protected Sparta, which meanwhile had joined the League and thereupon seceded, but punished a renewed defection so cruelly as to draw the censure of Rome. At Messene he likewise checked a revolt (189), but when that city again rebelled, in 184, he was captured in a skirmish and promptly executed. Philopoemen's great merit lies in his having restored

that military efficiency without which the Achaean League (*q.v.*) could never stand.

Polybius' *Histories* (x.–xxiii.) are our chief authority. These and a special treatise on Philopoemen (now lost) were used by Plutarch (*Philopoemen*), Pausanias, (viii. 49–51), Livy (xxxi.–xxxviii.), and indirectly by Justin (xxx.–xxxiv.).

PHILOPONUS, JOANNES (JOHN THE GRAMMARIAN), Greek philosopher of Alexandria, lived in the later part of the 5th and the beginning of the 6th century of our era. The surname *Grammaticus* he assumed in virtue of his lectures on language and literature; that of *Philoponus* owing to the large number of treatises he composed. He was a pupil of Ammonius Hermiae, and is supposed to have written the life of Aristotle sometimes attributed to his master. To Philoponus are attributed a large number of works on theology and philosophy. It is said that he was at first a Christian.

The more certain writings of Philoponus consist of commentaries on Aristotle. These include works on the *Physica*, the *Prior* and the *Posterior Analytics*, the *Meteorologica*, the *De anima*, the *De generatione animalium*, the *De generatione et interitu* and the *Metaphysica*. He wrote an attack on Proclus and probably two treatises on mathematics *A Commentary on the Mathematics of Nicomachus*, edited by Hoche (1864 and 1867), and a *Treatise on the Use of the Astrolabe*, published by Hase, the most ancient work on this instrument.

PHILOSOPHICAL ARTICLES. The most important philosophical articles contained in this Encyclopædia may be enumerated in three groups, namely (1) the key articles dealing either with the whole field or with one of the main divisions of philosophy; (2) articles devoted to particular philosophical schools or tendencies in the history of philosophy; and (3) articles dealing with special philosophical problems or topics. In addition to the articles here enumerated there are some 300 shorter articles dealing with various philosophical subjects, and about 400 articles of varying lengths devoted to individual philosophers:—

(1) **Key Articles.**—PHILOSOPHY, HISTORY OF; METAPHYSICS; KNOWLEDGE, THEORY OF; LOGIC; LOGIC, HISTORY OF; LOGISTIC; ETHICS; ETHICS, HISTORY OF; COMPARATIVE ETHICS; SOCIAL PHILOSOPHY; PSYCHOLOGY; PSYCHOLOGY, HISTORY OF; AESTHETICS; VALUE, THEORY OF.

(2) **Articles on Philosophical Schools and Tendencies.**—ACADEMY, GREEK; ARABIAN PHILOSOPHY; CAMBRIDGE PLATONISTS; CARTESIANISM; COMMON SENSE PHILOSOPHY; CYNICS; CYRENAICS; DUALISM; ECLECTICISM; EGOISM; ELEATIC SCHOOL; EMPIRICISM; HEDONISM; HOLISM; IDEALISM; INDIAN PHILOSOPHY; IONIAN SCHOOL OF PHILOSOPHY; JEWISH PHILOSOPHY; MATERIALISM; MEGARIAN SCHOOL; MONISM; NEO-HEGELIANISM; NEO-KANTIANISM; NEO-PLATONISM; NEO-PYTHAGOREANISM; PANTHEISM; PERIPATETICS; PESSIMISM; PHENOMENALISM; PLURALISM; PRAGMATISM; RATIONALISM; REALISM; SCEPTICISM; SCHOLASTICISM; SOPHISTS; SPIRITUALISM; STOICS; TRANSCENDENTALISM; UTILITARIANISM.

(3) **Articles on Special Problems.**—ABSOLUTE; ACCIDENT; ANALOGY; BELIEF; BODY AND MIND; CASUISTRY; CATEGORY; CAUSALITY; DURATION; EMERGENCE; EXPLANATION; FORM; FREEWILL; IMMANENCE; INDUCTION; INFINITE; INNATE IDEAS; INTUITION; LOGOS; METEMPSYCHOSIS; NATURE; PERSONALITY; PROBABILITY; QUALITIES: *Primary, Secondary and Tertiary;* RELATIVITY: PHILOSOPHICAL CONSEQUENCES; SUBCONSCIOUS; SCIENTIFIC METHOD; SPACE AND TIME; SUBSTANCE; THOUGHTS, LAWS OF; TRUTH.

(*See* also PSYCHOLOGICAL ARTICLES, and Articles on RELIGION and THEOLOGY.)

PHILOSOPHY, HISTORY OF. An adequate account of the history of philosophy would have to include not only the history of ethics, logic, psychology, metaphysics, etc., but also an account of the early history of science. For obvious reasons such a thing cannot be attempted here. Moreover, the histories of ethics, logic, and psychology have separate articles devoted to them, and the articles on aesthetics and theory of knowledge also contain the essentials of their history. As there are also separate articles dealing with the chief schools of philosophy and with the leading philosophers, the present article will only attempt to be a general guide to the study of the history of philosophy.

ANCIENT PHILOSOPHY

To all intents and purposes ancient philosophy is essentially Greek philosophy. This is not to deny the reality and value of Eastern philosophy. It is significant that even Greek philosophy commenced in the Eastern colonies, in Ionia, in Asia Minor, and that it was Ionian philosophers who introduced philosophy into other parts of Greece. It is also significant that Greek traditions refer to the influence of Egyptian teachers upon Thales, Pythagoras, Democritus, Plato and other Greek thinkers. Moreover, India, China and Persia, as well as Egypt, are known to have developed more or less independent world-views of their own. Students of oriental thought can trace therein counterparts of all, or nearly all, the main tendencies of Western philosophy—Monism and Dualism, Materialism and Idealism, Atheism and Pantheism, Pragmatism and what not. One may even point to certain direct oriental influences on Western philosophy in the case of Neo-Platonism in ancient times, in the case of Arabian or Moorish influences in the middle ages, and in the acknowledged influence of Buddhism on so modern a philosopher as Schopenhauer. But, it remains true that Western philosophy from Thales onwards is sufficiently self-contained to warrant separate treatment. And when the ground to be covered is enormous and difficult, it is a great convenience to be able to deal with the main stream of philosophy by itself. But there are separate articles dealing with Brahmanism, Buddhism, Indian philosophy, Arabian philosophy, Jewish philosophy, etc., for those readers who wish to go farther afield.

EARLY GREEK PHILOSOPHY

Ionian Philosophers.—A group of Ionian thinkers first raised the question as to the nature of the substance of which all things are composed, from which they originate, and into which they are dissolved again. Moreover they raised and answered this question in a non-mythological, impersonal manner. They considered *what*, not *who*, had produced all these things. Their answers were always in terms which we may be tempted to describe as *material*. But that would not be quite correct, because as yet no hard and fast line was drawn between the mental and the material. The ultimate matter of which they thought was a living matter—they were consequently not materialists but hylozoists. The Ionian group consisted of the following Milesians:

Thales (?640–550 B.C.) regarded water or moisture as the primary stuff or principle of things. In the then state of knowledge many physical phenomena must have appeared to bear out this view. For water is found in the form of gaseous vapour and of solids as well as in liquid form. In the phenomena of rising vapour and of sunbeams people saw the sun and other fiery bodies "drawing water" for their sustenance, so that water seemed capable of changing into fire. In the earth's absorption of rain, in the formation of deltas, in the alluvial deposits left by torrents, water appeared to be changed into earth. In the formation of dew and in the rising earth mists, earth seemed to change into moisture. And moisture was, of course, realized to be necessary for all living things. In these various phenomena Thales probably thought that he observed examples of the whole cosmic process from water and back into water.

Anaximander (?610–545 B.C.) was impressed by the conflicting character of such natural qualities as hot and cold, dry and wet, etc., and could not believe that water could generate things with qualities opposed to its own. He held that primary matter must be something different from any of the known determinate kinds of matter which have resulted from it. He accordingly identified primary matter with the "unlimited," by which he probably meant something indeterminate, out of which the determinate things, earth, water, air and fire, differentiated or "separated out." These four kinds, according to Anaximander, arranged themselves in successive layers with earth at the centre, followed by rings of water, air and fire in turn. The sun, moon and stars he regarded as masses of fire, flung off by the world's outer ring of fire, surrounded partly by husks or envelopes of air similarly flung off by the cosmic ring of air. Eclipses, he explained as due to temporary obstructions in the apertures of the air husks of the sun

and moon. Our world, which is only one of many, is cylindrical in form, and swings free in space.

Anaximenes (?590–525 B.C.) identified primary matter with air, because it has the greatest mobility and is indispensable to life. He was the first to attempt to explain the process by which primary matter gives rise to the vast variety of things. The processes he suggested are condensation and rarefaction. By condensation air is changed into water or earth; by rarefaction it is changed into fire. (*See* IONIAN SCHOOL OF PHILOSOPHY.)

Pythagoreanism.—The early Ionian or Milesian school of philosophy was brought to an abrupt end by the Persian conquest of Ionia. This calamity was followed by a revival of Orphic and similar mystery religions which influenced some of the philosophers, and so led to the foundation of the Pythagorean school.

Pythagoras (?570–500 B.C.) was a kind of philosophical revivalist. Influenced by the reawakening of religious interest among his contemporaries, Pythagoras endeavoured to combine religion with philosophy, and founded at Kroton (in southern Italy) a kind of religious brotherhood with a philosophic bias—something between a cloister and a college, in fact, the prototype probably of the mediaeval universities of Europe. In the history of thought the most noteworthy feature of the teaching of Pythagoras and his school is to be found in the stress laid on "form" rather than "matter," as the ultimate principle of things. The study of music taught Pythagoras that the concordance of a succession of notes depends on certain proportions between the lengths of the strings on which they are produced He was greatly impressed by this discovery of the importance of proportion And the discovery was applied in all sorts of directions. For example, one proportion of the elementary qualities of the body (hot and cold, dry and wet) constitutes health; another disease. It was also used as the key to the riddle of the universe. Numerical proportion thus came to be treated as the "principle" of things, in the same kind of way as the earlier philosophers had treated water, fire, etc., as primary matter. The Pythagorean view was expressed in the dictum that "all things are numbers." In order to understand this seemingly odd dictum, it is necessary to realize first of all how numbers were thought of at that time, and how easily numbers were then confused with geometrical figures. Numbers used to be represented by means of dots arranged in geometrical patterns, as they still are on cards and dominoes, *e.g.;* and numbers were described as triangular, or square, or oblong according to the geometrical arrangement of the dots representing them. Next, it will be observed that this custom rather encouraged the identification of the unit of number with the dot or point. And since lines can be analysed into the points, and planes into the lines, and solids into the planes that bound them, it could easily appear that it is the points that make the lines, that make the planes, that make the solids. And once the point was identified with the unit of number, it could be easily supposed that all things are constructed out of numbers. The Pythagorean doctrine is of importance chiefly because its idea of proportions or configurations was responsible partly for Plato's doctrine of "Ideas" and Aristotle's theory of "Forms." (*See* PYTHAGORAS.)

The Eleatic School, like the Pythagorean school, was founded in southern Italy by an Ionian refugee. Its centre was in Elea. Unlike the founder of Pythagoreanism the founder of the Eleatic school seems to have been nettled rather than carried away by the religious revival of the time, especially by the superstition which accompanied it. But the importance of the school lies in its metaphysics—it has, indeed, been described as the first really metaphysical school.

Xenophanes of Colophon (?570–480 B.C.), the founder of the Eleatic school, is chiefly noteworthy for his very scathing attack on the Homeric, Hesiodic and similar anthropomorphic conceptions of the gods. "Mortals," he remarked, "believe that the gods come into being as they themselves do, that they have senses, voice, body. . . . But if oxen or lions had hands, oxen would make gods like oxen, horses would make gods like horses." He himself believed in one God, altogether different from man. "There is one supreme God . . . like to mortals neither in body nor in thought." In fact, Xenophanes was a pantheist, as seems clear from his reported utterance: "The All is One, and the One is God." At all events this conception of the unity of Being or of ultimate reality, became the leading tenet of his school.

Parmenides of Elea (?540–480 B.C.) was the most important member of the Eleatic group. He is reported to have considered things "from the standpoint of the notion," that is, presumably, from the standpoint of their being intelligible or thinkable. The chief doctrines ascribed to him are expressed in the statements: "only Being is"; "birthless it is and deathless . . . for ever it stands a continuous One"; "all is full of being . . . no defect is there in it." Apparently he considered it unthinkable that anything should come into being out of nothing or pass into nothing. So he regarded reality as eternal—uncreated and imperishable. There is no empty space, "all is full of being," and so there is no possibility of motion. Reality was apparently a finite, spherical, motionless, continuous plenum, and change, movement and the very existence of ordinary discrete things illusory.

Zeno (?490–420 B.C.) supplied the best known arguments in support of Eleatic monism. His famous paradoxes were intended to show the absurdities involved in the position of pluralism, that is the view that reality is not one but a multiplicity, a many In opposition to the Pythagorean conception of reality as a multiplicity of spatial units, he argued that if so even a line must consist of an infinite number of points, and if each point has no magnitude then any thing must be infinitely small, but if the point has magnitude then each thing is infinitely great.

Melissus (?440 B.C) modified the teaching of Parmenides to the extent of regarding reality as infinite His contention was that if the real were finite it could only be bounded by empty space. Hence Parmenides' rejection of empty space really committed him to the view that reality is infinite Similarly, he regarded the non-existence of empty space as a reason for the impossibility of the existence of a multiplicity of discrete things. Being is one and immutable and can only be apprehended by thought. (*See* ELEATIC SCHOOL)

The arguments of Zeno and Melissus were largely directed against the views of Heraclitus, Anaxagoras and Empedocles.

Heraclitus (?540–475 B.C) held that fire is the primal matter The naturalistic trend of thought is very marked in Heraclitus, as is evident from the following fragment. "This one order of all things was created by none of the gods, nor yet by any of mankind, but it ever was, and is, and shall be—eternal fire—ignited by measure and extinguished by measure." Matter as conceived by Heraclitus is always changing and always moving, though its movements often elude our observation.

The world "begins" as a mass of fire, some changing partly into water. The water changes partly into earth and partly into vapour. The vapour returns to fire. The earth changes back to water, and from water to vapour and thence to fire again. And then the cycle of changes begins all over again, each complete stage being marked by a mass of fire at the beginning and at its end. The greatest service rendered by Heraclitus consists in his insistence on what may be called universal law—all changes begin "by measure." As regularity was naturally regarded as a sign of intelligence, Heraclitus posited the existence of "universal reason" side by side with primal matter, or as part of it, and regarded it as the one thing that is permanent in the ceaseless flux of changes. Another idea for which Heraclitus is noteworthy is that of the struggle for existence, which he conceived to characterize all things, and to be good for them.

Anaxagoras (?500–428 B.C) held that originally there was not one kind of primal matter but a multiplicity of all sorts of parts or "seeds" of things. These were all mixed up in chaotic confusion. But they were sorted out and arranged in an orderly manner by the "intelligence" or "reason" which pervades the universe. This reason is omniscient and omnipotent, but was still conceived by Anaxagoras in a semi-material fashion. This doctrine of the multiplicity of "seeds," through new combinations of which new things come into being, and by the separation of which they cease to be, paved the way for the atomic theory. The conception of "mind" or "reason" as introducing order into things was subsequently adapted by Aristotle. Most important, per-

haps, is the fact that Anaxagoras went to Athens about 462 B.C. and so helped to transplant Ionian philosophy to the city of Pericles.

Empedocles of Agrigentum (?483–430 B.C.) regarded reality as eternal, but not as one. It is composed of a multiplicity of elements or "roots." Of such "roots" there are four kinds, namely, earth, water, air and fire. These four kinds of elements combine to form the various things there are, and which cease to be when the component elements separate again. In order to account for the combination and separation, Empedocles postulated two entities or principles, namely, attraction and repulsion, or "love" and "hate." And as a physiologist he compared the relation of these two entities to the "roots" with the relation of air and blood to the living body. His quaint biological speculations are noteworthy for their implicit assumption of the conception of the "survival of the fittest."

The Atomists.—The pluralist opposition to the Eleatic conception of reality as a static, immutable One, culminated in the atomic theory This was first formulated by Leucippus (?500–430 B.C.), who first insisted on the reality of empty space, which used to be regarded as "non-being" But the atomic theory is chiefly associated with the name of his disciple, Democritus, who is commonly described as "the father of physics."

Democritus (?460–370 B C) is the most important Greek exponent of the atomic theory and the mechanistic method of explanation which is intimately associated with it. According to Democritus atoms and space are the only ultimate realities The atoms were conceived by him to be of various sizes and shapes. And all the main differences in composite bodies were reduced to differences in the (*a*) size and shape, (*b*) position, and (*c*) arrangement of the atoms composing them. The atoms may thus be described as the alphabet of the universe, and Aristotle actually illustrates these distinctions of Democritus by means of letters of the alphabet Using Roman instead of Greek letters, the above distinctions may be illustrated as follows. (*a*) The letters A and M are different in size and in shape; (*b*) the letters M and W are different in respect of position; (*c*) The syllables AM and MA are different in respect of arrangement The last distinction (*c*) is clearly reminiscent of the "Figure" or "Form" of the Pythagoreans. It is especially worth noting that the Atomists held that the atoms are naturally endowed with motion, and so avoided the problem, which perplexed all subsequent ages until the time of Newton, as to how passive matter was set in motion. The natural mobility of atoms seemed to require a void or empty space for them to move in. Hence the recognition by the Atomists of the existence of space Now the atoms flitting about in all directions collide, some of them get hooked together and combine in various ways owing to their various shapes; then the larger constellations of them enclose other atoms or smaller clusters of them, and so all sorts of things are produced, including whole systems or worlds Under certain conditions the various clusters break up again into separate atoms The systematic attempt to explain everything in terms of matter and motion necessitated then, as subsequently, the denial of the ultimate reality of the so-called secondary qualities—colour, sound, taste, smell, etc So the atomists dismissed them as mere "conventions," that is, as the effects of human intervention, or as merely subjective or illusory appearances. (*See* DEMOCRITUS)

THE GOLDEN AGE OF GREEK PHILOSOPHY

The Sophists.—After their victory over the Persians, the Greeks experienced something similar to the change of general outlook that was brought about by the great World War 24 centuries later. The desire for the good things of life spread among wider circles of people. And there was an increased desire for knowledge, at once as a good thing in itself, as a social and political aid, and possibly as a means to a new orientation after the shock to traditional beliefs and habits which is generally caused by a great upheaval like a war. The general demand for knowledge naturally produced a supply of popular teachers. And so the Sophists came into being These "wise men," or teachers of wisdom, rendered valuable services to the cause of general education. They not only helped to create a wider interest in philosophical and other problems but by their criticisms compelled greater thinkers to probe more deeply into the questions raised. Except among reactionaries, who, then, as always, showed hostility to the enlightenment of the people, the Sophists enjoyed a good repute among their contemporaries; it was only long afterwards that the term Sophist became derogatory. The most famous of the Sophists were Protagoras, Georgias, Hippias, and Prodicus. As teachers of the art of debate it was their business to show how to make the best of even a weak case In order to make a public display of their own skill in the art of defence it would have been futile merely to defend generally accepted views—anybody might do that. They could give much better proof of their skill by defending lost causes, paradoxes, views that seemed strange or even absurd at first—they had to "make the worse case appear the stronger," as Aristophanes complained The effect of all this was sure to be demoralizing upon some of the young Athenians And their criticism of existing social and political institutions was no doubt distasteful to some of the propertied and influential people. Hence their unpopularity with some In the history of philosophy their importance consists mainly in the interest which they aroused in ethical problems and in problems of knowledge The most important doctrine associated with their name is that enunciated by Protagoras in the dictum. "Man is the measure of all things." By this he meant that there is no such thing as universally valid knowledge Different people have different views, and for each person that is true which he, honestly and to the best of his ability, believes to be true Similarly with moral goodness In a world of merely relative standards, some of the Sophists maintained, it was no good pursuing truth, better to adapt oneself to the practical needs of life in the environment in which he finds himself. (*See* SOPHISTS)

Socrates (469–399 B C) was counted by his contemporaries among the Sophists For he, too, was interested in educating young people by means of discussions (though he taught without pay), he also was interested in problems of human conduct rather than in problems about the ultimate nature of reality; and he also did not see absolute truth in the opinions commonly entertained But, unlike the Sophists, he did believe in the possibility of knowledge, provided it were pursued in the right way And the way which he proposed is that known subsequently as the Socratic Method (*q v*) This method consisted essentially in checking one's ideas by constant reference to relevant instances until they are transformed into universally valid concepts or ideas. In essence it is an inductive method proceeding by elimination, though Socrates applied it to a sphere of problems in which the relevant data could be obtained by merely cross-examining people Ideas checked and corrected in this way so as to agree with the relevant facts are true, and altogether above the merely fluctuating opinions of men based on bare sense-perception, or tradition, or hearsay So convinced was Socrates of the possibility of real knowledge, and so impressed with its importance, that he based all else upon it, identifying moral good, or virtue, with knowledge By thus identifying virtue with knowledge, he may have thought that he also cured morality of the mere relativity which the Sophists had found in it Yet he was condemned as a corrupter of the young, and died as the first known martyr in the cause of philosophy (*See* SOCRATES)

The Successors of Socrates.—As Socrates had never given formal instruction and, moreover, left no writings behind him, it was easy and natural for different people to have different impressions of his teaching.

Aristippus and the Cyrenaics laid stress on the cheerfulness of Socrates and his capacity for reasonable enjoyment when an opportunity presented itself. They taught accordingly, a hedonistic ethic, with pleasure as the highest good (*See* CYRENAICS.)

Antisthenes and the Cynics on the other hand, were impressed chiefly with Socrates' indifference to hardships of every kind, his readiness to go without things when necessary. They accordingly preached the simple life, and *Diogenes* carried it so far as to reduce it almost to the life of a dog. (*See* CYNICS)

Euclid and the Megarians were interested mainly in Socrates'

conception of the nature of real knowledge, namely, that it consists of properly formed concepts, as distinguished from mere opinions based on mere observation. Accordingly, they adopted a rather sceptical attitude towards sense-perception and sense-objects, and developed, in connection with this sceptical propaganda, a form of disputation or eristic which became notorious for its excessive subtlety. But by far the most important of the informal disciples of Socrates was Plato, who, to some extent, shared the views of the Megarians. (*See* MEGARIAN SCHOOL.)

Plato (427–360 B.C.) first studied philosophy under a follower of Heraclitus. At the age of 20 he came under the influence of Socrates and remained in close touch with him until his death in 399. Plato then travelled for a while in southern Italy where he came into contact with the Pythagoreans. All these influences may be discerned in his philosophy, which they helped to shape. When in 387 Plato opened a school (the Academy) in Athens, the Pythagorean spirit betrayed its presence in the inscription: "Let no one who knows no Geometry come under my roof."

Plato's philosophy is one of epistemological and ontological idealism. The way in which he arrived at it may be briefly indicated as follows: He agreed with Heraclitus that all objects of sense-perception are in ceaseless flux, undergoing incalculable changes. No universal truth can therefore be asserted about this "ever-rolling stream." On the other hand, Plato also agreed with Socrates that real knowledge is possible, but only in the form of concepts or universal truths. So he concluded that the objects of real knowledge are not the ever-changing things of the sensible world, but supra-sensible objects which are immutable and eternal. These supra-sensible, eternal, immutable objects he called "Ideas" or "Forms." The world of change is not, indeed, a mere illusion. But it consists of things that have only a lower degree of reality, things that are but poor imitations of the corresponding "Ideas" after which they are named. Plato thus distinguished two principal types of object and two principal types of cognition corresponding to them. Real knowledge (or science, or the higher kind of cognition) has "Ideas" for its objects. Sense-perception is but "opinion," a lower kind of cognition, which has the world of change for its objects. Or, again, knowledge is concerned with the world of (eternal) Being; "opinion" is concerned with the world of mere "becoming" and passing away.

It is possible that what Plato really meant by his "Ideas" was the "laws" of things and events; that when he described the ordinary things of the sensible world as "copies" of the "Ideas" he simply meant that they conform more or less to those laws; and that the "copies" are poor in the sense that their conformity to law is only approximate, not exact. However this may be, Plato's conception of the world is that of a real *system*. But it is a teleological system, not a merely mechanical system. He gives expression to this conception by identifying the essence of the universe with "the Good." The conception was probably the result of Socratic influence. Socrates had identified the real character, or essence, of a thing with what it is good for. He had made enemies by his insistence that rulers and generals, etc., are not merely people who catch enough votes to be elected to office, but people who really know the business of a ruler, or of a general, etc., who really are "good for" the end in view. By extending this conception to all things, Plato conceived all things as adapted to various ends, these ends as subordinated or adapted to higher ends, and so on to a final end, "the Good," which is the purpose or ultimate end of the universe as a whole. (*See* ACADEMY, GREEK; ETHICS, HISTORY OF; KNOWLEDGE, THEORY OF; PSYCHOLOGY, HISTORY OF.)

Philosophy is an attitude of mind as well as a system of ideas. As an inspirer of the philosophic attitude Plato has never been surpassed, and but rarely equalled, if at all. Philosophy needs both the ideas and the attitude. Great philosophic ideas, indeed, are impossible without the philosophic attitude. But there is a kind of enthusiastic attitude that seems to be possible without ideas. And the teaching of philosophy has often suffered from it.

Aristotle. (384–322 B.C.) is in some ways the most important thinker in the history of ancient philosophy. It was he who gave to philosophy the articulation which it has retained more or less ever since. His writings (even in the incomplete and imperfect form in which they have been transmitted to us) contain contributions, and very important contributions, to all the main departments of philosophy, of most of which he may be regarded as the founder. And besides being the great architect of the whole structure of philosophy, and the most comprehensive or versatile of all philosophers, he also gathers up practically all that was best in ancient philosophy.

For 20 years Aristotle studied in Plato's Academy (367–347), and his own philosophy, though different in many ways from that of Plato, contains important Platonic elements. Undoubtedly Aristotle was more realistic, more empirical than Plato; and that will account for most of the other differences between them. But even that primary difference must not be exaggerated.

The general tendency of Plato's philosophy was to divide the universe into two parts, the relation between which he did not make clear. On the one hand, there was the world of becoming, of change, of sense, enjoying an inferior sort of reality; on the other hand, the world of being, the world of ideas, eternal and supremely real, and only remotely "copied" by the inferior world of change. Such, at all events, was Aristotle's interpretation of Plato, and he did not agree with such a disruption of the cosmos. While agreeing with Socrates and with Plato on the importance of ideas in the sense of concepts, if there is to be real knowledge, he felt that Plato's conception of "Ideas," and their aloofness from the particular objects of sense-perception, offered no explanation at all, for the relation of "copying" was a mere metaphor. Yet the primary business of "ideas" is to explain the world of experience, not merely to constitute an additional world.

The fundamental ontological conceptions in the philosophy of Aristotle are those of *Matter* and *Form*. The term *Form* is essentially equivalent to Plato's "Idea," which was itself an offspring of the Pythagorean "Form." The early Ionians were only concerned with the problem of primary *matter;* Pythagoras had been so preoccupied with "Form" that he almost forgot matter, or regarded "Form" as the primal matter or stuff of all things; Plato had removed the "Forms" or "Ideas" from the material world into a heaven of their own; Aristotle endeavoured to get a right conception of both matter and form, and of the relation between them. The conclusion at which he arrived was that form is immanent in matter, the ideal is immanent in the material, the universal is immanent in the particular; they are not generally divorced from each other, they are distinguishable but not separable. To understand Aristotle's view it is well to remember that he was the greatest biologist of antiquity, perhaps of all times. Plato was a geometrician, and that before the invention of co-ordinate geometry. His preoccupation was with ideal geometrical figures, eternal and static. His "Ideas" were conceived by his mind after the pattern of these eternal and static figures. Aristotle was a biologist preoccupied with the phenomena of growth and development, the transition from the potential to the actual, from the seed to the embryo, and from the embryo to the fully developed form of animal.

Aristotle, accordingly, was not perplexed by phenomena of change, and did not consider process incompatible with reality. And so he distinguished in all things matter from form, the relatively raw stuff from the relatively finished product. He applied the distinction all round, not to material things only. The distinction naturally cannot be quite the same in all cases, and it is relative in more senses than one. The "form" of a statue is a "shape" as distinguished from the marble which constitutes its "matter"; the "form" of a human character is a certain "organisation" of the instincts and impulses which constitute the raw material before they have been "licked into shape"; the "form" of a plant, an animal, a man consists of a certain "function"—nutrition, sensibility, and reason respectively—which distinguishes it from what is below it in the scale of existence; and so on. Again, nothing is entirely without "form." Even the block of marble has some shape before it becomes a statue; impulses and instincts have some sort of co-ordination at every stage in the process of character formation; and the things which in virtue of their several highest functions are plants, or animals, or men would still be something even in the absence of those functions, only

they would be different; that is, they would have different forms.

In the last resort, even the crudest kind of matter, the so-called four elements (earth, water, air, fire), recognized by Greek philosophers since the time of Empedocles (?483–430), were not regarded by Aristotle as pure formless matter, but as primal matter which had assumed different "forms" in consequence of the different combinations of their ultimate qualities (hot, cold, dry, moist). Pure, formless matter was simply a limiting conception. The whole state of any thing still capable of further development was regarded as "matter" in relation to the process, or function, etc., which would complete it, and which was called its "form"; yet within that so-called "matter" one would as naturally distinguish a "form" or something which distinguished it from a still less developed state or condition (actual or imaginary). In most cases, however, this series of relative distinctions has its limits. A material object, *e.g.*, cannot have less "form" than the four elements have. But there is usually also a limit to the highest "form" which certain kinds of matter can assume. A block of marble may become a statue or an image of some kind; it cannot become a plant, or an animal, etc. An acorn may become a sapling, and this sapling may grow into an oak, but it cannot grow into anything else. Still, though Aristotle believed in the fixity of species, he could compare the great and wonderful variety of things, and arrange them imaginatively in a kind of ascending series or "scale of nature."

Such a scale beginning with the lowest types of matter, with their suggestion of mere "formless" matter as an imaginary limiting case, and ascending through the various forms of life the "matter" of which becomes richer and richer in "forms" (when regarded from below) naturally suggested an upper limiting case; namely, some being who has realized the highest perfection or completeness, who cannot therefore be regarded as "matter" for further development, but only as "form." This highest being Aristotle identified with God. Like Plato's "Good," Aristotle's God was an "Idea" in Plato's sense (the only Platonic idea that Aristotle accepted), and the "end" or final cause of the universe. Aristotle conceived of all things as being somehow drawn towards God, and as going through the various processes of change and motion in consequence of this attraction. In this way, he conceived, God may, by His mere presence, cause all the changes and movements of things without Himself either moving or changing—He is the Unmoved Mover of the universe. For Aristotle, however, God is not the Creator of the universe. For the universe is eternal. Matter is eternal; and all the Forms are eternal, because there is no break in the succession of each Form's individual embodiments in matter. The effect of God's presence in the universe is that as the object of the world's desire He induces the already existing "matter" to develop its potentialities by assuming higher "forms." (*See* ARISTOTLE; LOGIC, HISTORY OF; ETHICS, HISTORY OF; KNOWLEDGE, THEORY OF; PSYCHOLOGY, HISTORY OF.)

ANCIENT PHILOSOPHY AFTER ARISTOTLE

Greek philosophy continued to flourish more or less for several centuries after the death of Aristotle. But its character was changed in some important respects. Plato and Aristotle attached supreme value to theoretical reflection as such. This is evident from their conception of God, for whom they could conceive no higher activity than thought. But Greek conditions in the latter part of the 4th century B.C. were not favourable to such disinterested thought. After the battle of Chaeronea, in 338 B.C., the Greeks lost their independence, and the Macedonian ascendancy, even if it was not an unmixed evil, created too many practical problems to leave much scope for abstract speculations. People who turned to philosophy did so mainly in search of some kind of moral or religious tonic. Hence the subordination of theoretical to ethical discussions in post-Aristotelian philosophy. The most important of the Greek schools of philosophy after Aristotle were the Epicureans, the Stoics and the Sceptics. They were all interested mainly in the moral problems of human life, and their history belongs chiefly to the history of ethics.

Epicurus (?341–271 B.C.) *and the Epicureans* put no intrinsic value on knowledge. Its value, according to them, consists entirely in its usefulness for practical purposes. The study of nature is useful mainly because it emancipates us from groundless fears and superstitions. The study of human nature also has some value as an aid to self-control. But most other studies they despised as learned lumber. Under the circumstances, they were not likely to make any valuable contributions to metaphysical theory. Yet we owe them something. As a reaction against the idealism and teleology of Plato and Aristotle, the Epicureans embraced the atomic theory of Democritus with its mechanistic explanations of all things. Even the soul was regarded as corporeal, "composed of fine particles dispersed all over the body, most nearly resembling wind with an admixture of heat"; for, says Epicurus, "it is impossible to conceive anything incorporeal except empty space"; "hence those who call soul incorporeal talk foolishly." In the 2nd century B.C. Epicureanism obtained a foothold in Rome, and there produced its most famous exponent in *Lucretius* (95–51 B.C.), whose poem, *On the Nature of Things,* contains the classic account of ancient atomism. In ethics they developed the hedonism of the Cyrenaics. While regarding pleasure as the only good, they distinguished different kinds, as well as degrees of pleasure, valuing mental pleasures, especially those resulting from the practice of virtue, above all others. (*See* EPICURUS; HEDONISM; ETHICS, HISTORY OF.)

Zeno (?336–264 B.C.) *and the Stoics* also attached no intrinsic importance to knowledge. They valued it only as an aid to virtue and judged truths pragmatically. Just as the Epicureans adopted the atomist philosophy instead of evolving a philosophy of their own, so the Stoics adopted, with modifications, the philosophy of Aristotle, which they changed into a pantheistic view. Substituting the concepts "body" and "soul" for the Aristotelian "matter" and "form," they conceived the universe as an organic whole, having both body (or matter) and soul (or force, or reason). All things are but parts of the one organic universe, which pursues a rational course and directs the development of all its parts. So completely rational and in conformity with universal law was the "One and All" conceived to be that no room was left for arbitrariness or caprice. It is at once God and Nature, Providence and Destiny. A hymn composed by the Stoic *Cleanthes* (?331–233 B.C.) is one of the most famous expressions of pantheism in the history of literature. With such a conception of nature the Stoics naturally identified virtuous conduct with life according to nature, and this it could only be by being in harmony with the universal reason pervading nature. Rational self-control was set up as the only good, because it makes one independent of external circumstances, free and contented. As with Epicureans so with the Stoics, one of their most celebrated members was a Roman—the Emperor *Marcus Aurelius* (121–180 A.D.). (*See* STOICS; ETHICS, HISTORY OF; LOGIC, HISTORY OF; PANTHEISM.)

Pyrrho (?360–270 B.C.) *and the Sceptics* were much more interested in philosophic theory than were the Epicureans or the Stoics. They paid special attention to epistemology. But the conclusions they arrived at were not flattering to human knowledge so-called. Pyrrho was of opinion that things are too incalculable and unaccountable to warrant any conviction whatever, so that the right attitude of mind is one of sceptical neutrality. Such an attitude has its advantages, for it is conducive to peace of mind. Most troubles, he held, are disappointments resulting from rash judgments and anticipations. Those who renounce all claims to knowledge might attain to the same equanimity which the Epicureans and Stoics sought to attain with the aid of knowledge. The most important of the Sceptics was *Carneades* (213–129 B.C.). He carried on a systematic campaign against the dogmatic assumptions of his predecessors and contemporaries, attacking more especially the tendency of the Stoics and others to identify cosmic regularity with a cosmic reason, the widespread habit of ascribing human attributes to God, the entirely insufficient evidence on the strength of which God's existence was believed in, and the habit of ignoring the existence of unmerited evil in order to exonerate God from all responsibility for it. Even Hume (1711–1776) and other modern sceptics did little more than adapt the arguments of Carneades. (*See* SCEPTICISM.)

Ethically, the three schools, Epicureans, Stoics and Sceptics,

were really very similar. They all regarded peace of mind as the highest good attainable, and they all emphasized the need of emancipating oneself from the bondage of external circumstances.

Philo (?25 B.C.–A.D. 50) *and the Neo-Platonists.* One result of Macedonian ascendancy has already been pointed out in explanation of the predominance of ethics in post-Aristotelian philosophy. Another effect it had was that it tended to break down national barriers. The different nationalities under Macedonian sway were thrown together, and Greek thinkers were brought into touch with the East. The cosmopolitanism of the Stoics was probably influenced by this. But Neo-Platonism is a more obvious result of the contact between East and West. Alexandria was the great intellectual centre where East and West met together. The East needed more philosophy, the West more religion, and Neo-Platonism was an attempt to make the best of both. The philosophy which had a very marked religious side was that of Plato. The new movement, accordingly, was first regarded as a form of Platonism. Eventually, however, it was re-named Neo-Platonism. Of the early Neo-Platonists the best known is *Philo Judaeus* of Alexandria. He was the head of a group of cultured Jews who tried to harmonize Hebrew religion with Greek philosophy. By interpreting the Bible allegorically, Philo sought to read Platonism into Hebraism and Hebraism into Platonism. But Neo-Platonism owes its success mainly to *Plotinus* (A.D. 204–270) and *Proclus* (410–485). This school also may claim a distinguished Roman as one of its adherents; namely, the Emperor *Julian the Apostate* (reigned 361–363).

According to Plotinus, the ultimate source of all things is God, of whom it is impossible to predicate anything, because He is logically prior to anything that can be predicated. Now, God, acting on a creative impulse, created a Spirit (νοῦς) somewhat like Himself. This Spirit, acting on a like impulse, created another, namely the World-Soul. This created other souls, and so on until the series of productions in accordance with the law of diminishing spiritual returns ends in that extremely low kind of souls called matter. The process of creation is usually conceived as a kind of emanation, analogous to the sun's emission of light; sometimes, however, creation seems to be reduced to a logical or quasi-logical relationship. The World-Soul (the creation of the first Spirit created directly by God) is conceived as a group or system of spirits very like the Platonic "Ideas," at once thoughts and objects, but perfect and immutable. As the creations or emanations are held to be immanent in the creators, the Neo-Platonist universe in really one spiritual system, all the parts of which are spiritual though in varying degrees. The human soul has fallen from a higher grade of spirituality, and can only regain this by a training in asceticism and mysticism and after a series of successive births. The Neo-Platonism of Plotinus, with its system of graded spiritual emanations from God, was readily adapted to the then prevalent Polytheism and belief in spirits and spectres of all sorts. Greek paganism thus received a new lease of life under Julian the Apostate. Plotinus also criticized the Christian exaggeration of man's place in the universe and of the importance of prayer without work. (*See* NEO-PLATONISM; PHILO; PLOTINUS; PROCLUS.)

Cicero (106–43 B.C.) *and the Eclectics.* Philosophers who neither construct a system of their own nor embrace an existing system as a whole, but adopt and combine parts belonging to different systems, are called eclectics or syncretists. The term Eclecticism is sometimes applied with great latitude so as to include even such comparatively harmonious systems as Neo-Platonism, but is more usually restricted to the less systematic and more loose jointed philosophies. In 146 B.C. Greece became a Roman province, and Rome developed philosophic ambitions without ever succeeding in constructing an independent philosophic system. It was probably in keeping with the essentially practical mentality of the Romans to refrain from speculation beyond a certain point, and to trust their common sense instead of following theoretical adventure "whithersoever it may lead." The most famous eclectics of antiquity were Cicero and Seneca (A.D. 5–65). Both showed marked leanings towards the epistemology of the Sceptics of the New Academy and the ethics of the Stoics. Cicero also leaned somewhat towards Stoic pantheism, and Seneca has impressed many people as remarkably Christian for a pagan. Of course, there were eclectics outside Rome. Perhaps the best known of them was the Greek, *Plutarch* (A.D. 50–120). (*See* CICERO; SENECA; PLUTARCH.)

The End of Ancient Philosophy.—In A.D. 529 the Emperor *Justinian* closed the school of philosophy and so brought to an end the first main period in the history of philosophy. During the dark ages, which followed, the writings of the eclectics, and especially those of Cicero, did much to keep alive a knowledge of ancient philosophy and an interest in philosophical problems.

MEDIAEVAL PHILOSOPHY

Greek philosophy had started as a rational reaction against the mythologies of popular religion, and in Athens at least three Greek philosophers (Anaxagoras, Socrates and Aristotle) suffered persecution, one of them even death, on account of their alleged hostility to popular religion. In the middle ages the tables are turned. Popular religion has the upper hand, and philosophy becomes the handmaid of theology. There is no independent mediaeval philosophy. It is not original but borrowed from the past; and it is not free, but subordinate to authority—the authority of books or of an organized Church. This is true more or less not only of Christianity, which played the leading rôle in the middle ages, but also of Judaism and of Islam. When philosophy was not simply denounced and ignored, it was exploited in the interests of the Christian, Jewish or Mohammedan epic, not to say mythology. Some would go so far as to refuse the name philosophy to thought so restricted. But it is impracticable to draw a hard and fast line. On the one hand, even Greek philosophy was, perhaps, never entirely purged of elements of mythology. On the other hand, even mediaeval thinkers, by a subtle use of allegorical interpretation, managed to fit Scripture to their philosophy instead of modifying their philosophy to fit Scripture, and so gained a measure of freedom of thought.

PATRISTIC PHILOSOPHY

Mediaeval philosophers were for the most part Christian theologians, and a detailed history of their views belongs to the history of Christian dogma rather than to the history of philosophy. Here our business is only with the limited philosophical aspect of that complex and interesting story. Christianity did not set out to be a philosophy, but a moral and religious stimulus. Its interest was in the lowly rather than in the "high-brow." It was suspicious of philosophy and uttered a warning against it. "Take heed lest there shall be any one that maketh spoil of you through his philosophy" (Col. ii., 8). And at least one Apostolic Father (Tertullian) not only did not mind it if his faith was unphilosophical, but was almost proud of it—*credo quia absurdum.* In course of time, however, it was found necessary to make use of philosophy partly in order to repel the attacks of hostile philosophers, partly in order to spread the gospel among philosophically-minded heathens, and partly in order to satisfy the needs or tastes of Christians with a turn for philosophy. Early in the 2nd century already Alexandrian Christians, like Alexandrian Jews, resorted to allegorical Neo-Platonist interpretations, as is clear from the "Logos" doctrine in the so-called *Gospel of St. John.* Some of the "Gnostics" even tried to combine loyalty to Jesus with loyalty to Pythagoras, Plato and Aristotle. For some time, however, the chief use made of philosophy was for purposes of defence (apologetics). This was the case with the Church Fathers, notably *Justin Martyr* (d. 167), *Tertullian* (150–220), *Clemens of Alexandria* (d. 215), *Origen* (185–254), and, above all, *Augustine* (354–430).

The Patristic period, as it is called, is characterized by its Platonic or Neo-Platonist tendency, for which the influence of Augustine secured a certain predominance in Christian thought for a long time afterwards. Augustine had been a sceptic, among other things, before he became a saint, so he felt it necessary to refute scepticism before attempting a constructive philosophy. His method was that adopted later by *Descartes.* There are many things, he said, that are dubious. But there is one thing that is indubitable even in the state of doubt, namely, the actual

experience of doubting. And one could not doubt unless he was alive and thinking, and aware that there is such a thing as truth. So we are certain of something. But how? Not by external perception but by inner intuition. Augustine next proceeds, like Plato, to distinguish two types of reality—an "intelligible world" (of "ideas" or "forms") which is apprehended by intuition, and a "sensible world" (of mere "copies" or "imitations" of the "ideas") which is apprehended in sense-perception. Intuition affords real "knowledge"; sense-perception, mere opinion. Eternal truths (like those of mathematics, for example) are objective and transcendental. They are emanations or radiations from God. The human soul may apprehend them, but does not create them. God, then, is the source of the eternal truths. He creates things by thinking them; and He has created the world out of nothing. But things were not all made by Him directly. God only created matter and endowed it with the seeds of further development. With such changes time came into being; but God is beyond time —He is eternal. Temporal things only endure so long as God maintains them by continuous creation. Man is a miraculous union of an "intelligible" and a "sensible" substance. The soul, as the possessor of eternal truths, is immortal.

Patristic philosophy attained its climax in Augustine, and little else of the thought of that period, and for several centuries afterwards, is of sufficient philosophical interest to be worth mention in a mere outline of the history of philosophy. As a whole Christendom relapsed into intellectual darkness, and did not open its eyes again until several centuries afterwards.

ARABIAN AND JEWISH PHILOSOPHY

Arabian and Muslim Philosophy.—When the Athenian schools of philosophy were closed in 529 many of the teachers migrated to Syria and Persia and stimulated philosophical interest in the Muslim world. This interest was intensified when in 641 the Arabs captured Alexandria, which was then the greatest seat of learning, with a long and honourable tradition behind it. By 711 the Muslims had swept through Arabia, Syria and Mesopotamia, and even along the African coast of the Mediterranean as far as the straits of Gibraltar, and went into Spain. (The "Moors" of Spain were Arabs from Mauretania, that is, North Africa.) In this way philosophy was kept alive in Islam and in due course brought back to Christendom. The most important Muslim philosophers were Al Kindi (d. 870), Alfarabi (d. 950) and Avicenna, or Ibn Sina (980–1037) of Baghdad, and Averroes (1126–1198) of Cordova, in Spain. They were familiar with nearly all the works of Aristotle, and with several of Plato's treatises. Their philosophy was Aristotelian in the main, but blended with Platonism. The most interesting feature in Avicenna is his discussion of the problem which subsequently became one of the most burning questions among the Christian Scholastics, namely, the problem of the relation of the universal to the particulars of which it is predicated—the bone of contention between the so-called Nominalists and Realists of Scholasticism. And his solution was this. Universals existed in the thought of God already before the corresponding particulars came into existence; but they were then embodied in the particulars; and are derived by the human mind from these by a process of abstraction.

Averroes was the most Aristotelian of all the Muslim philosophers, and the most important. According to Averroes, there is a sub-lunar world of imperfection and change, and another, higher, eternal world beyond the stars. Matter is eternal, and contains from the first certain seminal "forms" which develop it from the merely potential to the actual, or final, state, under the influence of the higher "forms," or "intelligences," or in the last resort, of God. The human soul is inseparable from the body, or rather the brain, and perishes with it; but the "reason" that dwells in man is immortal, and by cultivating it man may enter into union with the universal "active reason." (*See* ARABIAN PHILOSOPHY.)

Jewish Philosophy.—Already in pre-Christian times there existed among the Jews a kind of philosophical mysticism which resembled Neo-Platonism in some respects. It is possible that Philo, the Jewish founder of Neo-Platonism, came under its influence at one time. This mystical doctrine is known as the *Kabbalah* (Hebrew for "traditional lore"). But it is difficult to trace its history with accuracy, as its two principal documents—the *Yepher Yetzirah* ("Book of Creation") and the *Zohar* ("Book of Splendour")—are compilations which are not much earlier than 900 and 1300 respectively. Side by side with this movement, however, there grew up, a more genuine philosophy under the influence of Plato and Aristotle. This movement had two interesting periods, namely, the Alexandrian period, about the beginning of the Christian era, in which Philo and various other Egyptian Jews flourished, and the Spanish period, from about the 10th till the 14th century, when many Jews vied with the Moors in the cultivation of Platonic and Aristotelian philosophy.

The favourable conditions under which Jews lived, during these centuries, throughout the Muslim world encouraged their participations in the interest which Islam then took in philosophy. In Baghdad and in Cairo, in Cordova and Toledo, they kept abreast of their Muslim neighbours. Numerous as were the Mohammedan schools and sects produced by the study of Greek philosophy, almost every one of them was reflected in contemporary Jewish thought. Traditionalism and anti-traditionalism, rationalism and dogmatism, fatalism and voluntarism, Platonism and Aristotelianism—all these and other tendencies had their Jewish counterparts, and almost every Muslim philosopher of repute had his Jewish double. This does not argue imitation but a similar susceptibility to similar influences. During the 10th and 11th centuries Platonism and Aristotelianism were about equal in favour. The chief Jewish thinkers of this period were Israeli (between 850 and 950), the author of a treatise *On the Elements;* Seadiah (892–942), author of *Faith and Philosophy;* and Bachyah Ibn Pakuda (?1000–1050), who wrote a *Guide to the Duties of the Heart.* To this period belongs also the Jewish Neo-Platonist and poet Ibn Gabirol (?1020–1070), whose *Fons Vitae* ("Fountain of Life") was probably the first book to re-introduce Greek philosophy into the West after the close of the dark ages. During the 12th century, Aristotelianism gained in influence, and enjoyed almost undisputed supremacy during the 13th and 14th centuries. The most important Jewish thinkers of this period were Maimonides (1135–1204), author of the *Guide of the Perplexed;* Gersonides (1288–1344) author of *The Wars of the Lord;* and Crescas (1340–1410), author of *The Light of the Lord.*

These Jewish philosophers served the interests of subsequent philosophy in two principal ways. They helped to make the works of Plato and Aristotle accessible to the Scholastics by helping to get them translated from the Arabic versions into Latin, frequently through the medium of Hebrew. (The transmission was thus very roundabout, as the Arabic versions were in their turn usually based on Syriac translations made by the Nestorians from the Greek originals.) But some of them also exercised a more direct influence on the Scholastics. Avicebron's *Fons Vitae* (the Jewish origin of which was not suspected for many centuries) had no small share in moulding the thought of Duns Scotus, among others. And Maimonides exercised an equally strong influence on others, among them the two most important Scholastics, Albertus Magnus and Thomas Aquinas. Maimonides and Crescas also influenced Spinoza in some ways, and both are referred to by him. (*See* JEWISH PHILOSOPHY.)

SCHOLASTICISM

In the meantime various tendencies were preparing the way for a re-awakening of Christian interest in philosophy. The schools founded throughout France by Charles the Great, in the 8th century, were sufficiently developed in the 9th and 10th centuries to take up some philosophic problems, a faint interest in which had been just kept alive by various mystics and Neo-Platonists. The teachers who taught the so-called seven liberal arts at these schools were known as *doctores scholastici.* (The seven liberal arts were grammar, logic, rhetoric, arithmetic, geometry, astronomy and music.) But the name was applied later to all who taught philosophy and theology, especially at the new universities of Paris, Bologna, Salerno, Oxford and Cambridge, which were all founded during the 11th and 12th centuries.

The chief aim of the Scholastics was to reconcile Christian theology with philosophy. The first prominent Scholastic was John Scotus Erigena (810–877). He insisted on the harmony of Christian dogma with reason, as God is the author of both. Under the influence of a kind of Neo-Platonic mysticism he teaches the idealistic doctrine that things only exist in so far as they are known, that the universal ideas by which they are said to be known are the only ultimate realities and produce the so-called things.

This kind of view about the reality of ideas, now usually called "idealism," was known as "realism" in the middle ages. (Later on "realism" meant, and still usually means, the view that material things are also real, which extreme idealism denied.) In course of time the problem of the reality of universals became a burning question among the Scholastics. It was usually raised in connection with Porphyry's discussion of Aristotle's predicables, but that was a matter of chance; it would probably have arisen in any case in connection with the study of the differences between Platonism and Aristotelianism. Until late in the 11th century, under the predominant influence of Platonism or Neo-Platonism, "realism" was the usual view Roscelinus (?1050–1121) was the first "nominalist," that is to say, he denied the independent reality of universals, and regarded general terms as mere names. For a long period, however, he had no following. Anselm of Canterbury (1033–1109) was a pronounced realist. He also formulated the characteristic view of Scholasticism that faith must precede knowledge—*credo ut intelligam*.

An innovator was Abelard (1079–1142), famous for his association with Heloise. His view of universals was rather like that of Avicenna. He held that universals are embodied in the individual things The "forms" or "ideas," however, are conceived by God from all eternity. The human mind only gets to know them by abstraction from particulars. So universals exist *ante res, in rebus*, and *post res*. Abelard is noteworthy for his defence of doubt. He claimed a certain value for it inasmuch as doubt leads to enquiry, and enquiry leads to truth. In his ethical treatise *Scito te ipsum* ("Know thyself"—the first separate ethical treatise in the middle ages) Abelard shows himself comparatively tolerant towards pagans, Jews and philosophers or freethinkers.

The Crusades (1097–1290) brought Christendom into contact with Eastern learning and so helped to promote a fuller knowledge of Platonism and Aristotelianism, especially the latter, as expounded by Arabian and Jewish philosophers This tendency made a good beginning when in 1085 Toledo fell into the hands of the Christians who thus came into possession of numerous philosophical manuscripts. And the movement reached its climax when in the course of the 13th century Aristotelian manuscripts in the original Greek found their way gradually from Constantinople to the new centres of European learning. Aristotelianism, rejected by the Church in the early part of the 13th century, grew rapidly in favour, especially in the Dominican order, which produced the two greatest Aristotelian Scholastics, namely, Albertus Magnus (1193–1280) and Thomas Aquinas (1225–1274), Albertus wrote voluminous expositions of Aristotelianism with the help of Arabian and Jewish commentators, especially Avicenna and Maimonides. In the realm of natural knowledge he respected the authority of Aristotle as much as he trusted Augustine in the sphere of Christian faith In fact, it was he who first distinguished sharply between *natural* and *theological* knowledge—a distinction of no little importance in the history of Scholasticism, and even later.

Aristotelian Scholasticism culminated in Thomas Aquinas. He also emphasized the distinction between natural and theological knowledge, between the light of reason (*lumen naturale*) and the light of revelation, and even admitted, in principle, the autonomy of the former. In practice, however, he subordinated natural to theological knowledge in the sense of making the former aid to the latter. Philosophy is thus treated as the handmaid of theology, and nature as the mere forerunner of grace, though grace is alleged to crown nature, not to reject it. The distinction, though difficult or impossible to maintain, turned out to be helpful inasmuch as it rendered possible a certain amount of independent thinking in the realm of nature, so long as no reference was made to the concepts of historical Christianity (which constituted the realm of grace). Like Aristotle Aquinas laid great stress on the distinction between matter and form, though he is rather liberal in his conception of the numerous "forms" capable of existing apart from matter. The human soul, though associated with a body, is also capable of separate existence. It is the lowest of the "separate forms," of which there is a scale ascending through all kinds and degrees of angels and spirits (including those which guide the stars and their courses) and culminating in the "absolute form," namely, God. By assuming that God had conferred a measure of autonomy upon nature, Aquinas further facilitated to some extent the possibility of an autonomous philosophy or science. His conception of the character of human knowledge also tended in the same direction Instead of regarding it (as Augustine had done) as a direct divine illumination, Aquinas conceived it to be produced by images which external objects deposit, so to say, in the soul. Empirical studies thus received some recognition. On the question of universals the view of Aquinas was that one "form" is embodied in all the material objects of the same class, and that their matter is responsible for their particularity and multiplicity In the case of Angels, etc., that is, immaterial forms, there is no such multiplicity of replicas, so to say—each form is unique Our knowledge of material objects *qua* particulars comes through our senses, but their "form" is apprehended by the intellect.

The Aristotelianism of the Dominicans was opposed by the rival Franciscan order, the principal representative of which was Duns Scotus (1217–1293). He strongly opposed the intellectualism of Aquinas and repudiated the endeavour to harmonize faith with knowledge, theology with philosophy, and rather emphasized their antagonism. What is true in philosophy may be quite false in theology, which leaves no room for philosophical dialectics. Whereas Aquinas regarded knowledge as primary, and will as dependent on knowledge, Duns Scotus claims primacy for the will, which he treats as the fundamental faculty of the soul. Imagination and conception are entirely subordinate to the will, with which the decision always rests, and which is free from all possibility of coercion. The good is above the true And the good is good because God has declared it such (Aquinas maintained that God ordained certain things because they are good) Things are what they are because God has arbitrarily made them so. And the duty of man is to will to obey God's commands On the question of universals Duns Scotus upheld the same kind of realism as did Anselm, Avicenna and Aquinas The doctrine of the primacy of the will was adopted later by Descartes.

The teaching of Duns Scotus concerning the irreconcilable antagonism between philosophy and theology, and concerning the arbitrary character of divine creations and decrees was carried even to greater extremes by William of Occam (d 1347). He maintained that philosophy is utterly incapable of proving the existence of God, or demonstrating His attributes. From this bankruptcy of the natural light of reason he infers the necessity of revelation. He carries his conception of the good, as the arbitrary decree of God, so far as to maintain that a so-called evil deed is not evil if it is done in the service of God In opposition to the moderate "realism" of the Dominicans, Occam revived the nominalism of Roscelinus and maintained that universals are merely subjective conceptions, all real things being individual or particular. To posit real universals in addition to the corresponding particular objects is an uncalled for duplication It was in this connection that he formulated the familiar principle, commonly known as "Occam's Razor," *entia praeter necessitatem non sunt multiplicanda*—the number of entities should not be increased unnecessarily. After Occam, Scholasticism rapidly declined in influence. In one form or another it continued, of course, and continues to this day. It has even enjoyed various revivals. But its power was broken by the onward march of that great combination of forces called the Renaissance or Revival of Learning. (*See* SCHOLASTICISM; KNOWLEDGE, THEORY OF.)

MODERN PHILOSOPHY

Transition.—Subordination to authority was the chief characteristic of mediaeval thought. It took many generations and diverse influences to break the power of ecclesiastical authority, and to secure autonomy for philosophy. No doubt authority was a guide as well as a task-master, a support as well as a rod, during the adolescence of mediaeval thought. Greek thought did not allow itself to be shackled by tradition or by authority. On the other hand, a great deal of the thought of Christendom, even in the "modern" period, can hardly claim to be free from the marked influence of Christian tradition and authority. So it would be a mistake, on the whole, to think of ecclesiastical authority in the middle ages as a tyranny imposed entirely from outside. But thought had to come of age sooner or later And many influences helped it towards maturity. When Constantinople was threatened by the Turks, the Greek scholars there fled to Italy carrying their classical treasures with them One of them, *Pletho* (?1355–1450) persuaded Cosimo de Medici to found a Platonic Academy in Florence. With the co-operation of *Marsilius Ficinus* (1433–1499), *Pico de Mirandola* (1463–1494) and others, Platonic and Neo-Platonic philosophy made headway against Aristotelianism on which Scholasticism was based Writers like *Lorenzo Valla* (1408–1457) attacked Scholasticism for its sins against literary form, and its interest in words instead of things. *Nicolaus Cusanus* (1401–1464) showed pantheistic and scientific leanings, and believed not only in the spherical form of the earth, but also in its rotation about its axis.

Paracelsus (1493–1541) and *von Helmont* (1577–1644) denounced "authority" and mere book learning in the study of natural phenomena; although their own methods had little to commend them. *Telesio* (1508–1588) founded an academy at Naples to promote the study of nature on scientific lines He embraced the ethics of the Stoics, and introduced the conception of a self-preserving impulse somewhat like that formulated subsequently by Spinoza Very important in many ways, during this period of transition, was *Giordano Bruno* (1548–1600), whose martyrdom marked the first open breach with the Church. He was at once pantheist and atomist, and gave currency to the conception of "monads" of varying grades with God as "the monad of monads." Some of his ideas reappeared later in Spinoza, Leibniz and Schelling *Montaigne* (1533–1592) and *Sanchez* (1562–1632) attacked dogmatism with the weapons of scepticism, and pleaded the cause of toleration But most important of all was the progress of science and the growth of the scientific spirit through the achievements of *Copernicus* (1473–1543), *Kepler* (1571–1630), *Galileo* (1564–1642) and *Newton* (1642–1727); *Vesalius* (1514–1564), *Fabricius* (1537–1619), and *Harvey* (1578–1667); *Gilbert* (1540–1603), *Boyle* (1627–1691) and *Huygens* (1629–1695).

Modern philosophy owes little or nothing to the Reformation. The Reformers (Luther, Calvin and Zwingli) were as intolerant as possible. Luther denounced reason as the mistress of the devil, and Calvin committed Servetus to the flames, in 1553, with as much Christian charity as the Inquisition showed to Bruno in 1600. All that can be said is that the dissensions between the Churches indirectly stimulated a certain amount of independent thought among thoughtful people, and so reinforced a similar tendency encouraged by the mystical movement which, though it only produced few geniuses like Eckhard (1260–1327) and Böhme (1575–1624), had never entirely ceased in Christendom. Francis Bacon (1561–1626) must also be mentioned here. He described himself as the herald of modern thought, and perhaps rightly so. He showed rather less originality than his namesake Roger Bacon, who preceded him by three centuries But he summed up very effectively all the grievances against Scholasticism The place of honour as father of the new philosophy is usually given to Descartes. Many of his contemporaries certainly regarded Descartes as the founder of a new philosophy. So one may as well date modern philosophy from Descartes.

FROM DESCARTES TO LEIBNIZ

Descartes (1596–1650), like Bacon and others before him, was dissatisfied with the state of knowledge in his time. Mathematics was the only study that seemed to be well founded. And he thought that the difference was due to a difference in method. Other studies then followed the scholastic method of citing authorities for and against certain views. With mathematics it was different. It did not depend on authorities, but set out from certain clear ideas (axioms, postulates, definitions) and then proceeded deductively from them to results which were not challenged and contradicted constantly as were the results reached by different thinkers in other fields of study. Descartes resolved, accordingly, to introduce something essentially like the mathematical method into philosophy. The first requisite was a sure starting point, an Archimedean fulcrum, as Descartes called it. In order to discover it he adopted from Augustine the instrument of "methodical doubt" rejecting everything that was open to doubt until he could discover something indubitable. Like Augustine he found that though everything else could be doubted, the reality of the doubt itself could not "It is easy to suppose that there is no God, no heaven, no bodies, and that we have no hands, no feet, no body; but we can not in the same way conceive that we who doubt these things are not; for there is a contradiction in thinking that that which thinks does not exist when it thinks. Hence the conclusion I think, *therefore I am* is the first and most certain of all that occurs to one who philosophizes in an orderly way" (*Principles of Philosophy, I*, vii). This conclusion, however, is only accepted because it is "clear and distinct" Hence the general rule that "whatever I apprehend very clearly and distinctly is true" (*Meditation* III.).

Among such very clear and distinct ideas he includes that of God, the axioms of geometry and such already familiar "eternal truths" as *ex nihilo nihil fit*, etc , which he also calls innate ideas, in the sense that they are not derived from experience, but are evolved, in due course, by the immanent power of thought itself. Still, Descartes finds it necessary to prove the existence of God, and his main arguments are borrowed from Anselm and Campanella. Next, relying on the veracity of God, he accepts the reality of the things of the world of experience, with the reservation that error arises when we believe what is not very clear and distinct Such error is possible because belief or judgment is an act of will according to Descartes, who with Duns Scotus believed in the primacy of the will As to the nature of real things, God is the only self-existent being (or substance in the strict sense) on whom all other things depend for their creation and continuance Of created things there are two main types, namely, "extended things," or bodies, and "thinking things" or minds These are created substances, or substances in a secondary sense Like Augustine Descartes regarded the material and the mental as so utterly different and opposite that there can be no interaction between them. The union of body and soul in man is simply a miracle, whereby the soul (with the help of God—*concursus Dei*) can *direct* the motion of the body, but not add to it in any way. When discussing problems which do not directly concern God or man, Descartes shows a much more scientific spirit, though his scientific contributions were of little value except in relation to geometry, to which he rendered services of first-rate importance.

Like Galileo, his senior contemporary, Descartes attempted to explain all natural phenomena mechanically and consequently denied the objective reality of secondary qualities The lower animals he treated as mere automata or machines; and by attributing an imaginary function to the pineal gland and resorting to the antiquated "animal spirits" of Galen, he tried to introduce at least something mechanical into the relation between the body and the soul. This was not consistent with his conception of the opposed natures of bodies and minds. His followers, accordingly, tried another explanation, known as "occasionalism." According to this view, body and soul do not influence each other at all, but any change in either is an occasion for divine intervention in the other, so as to produce a corresponding change. This, of course, is supernaturalism pure and simple; and that is what Cartesian philosophy is essentially The striking difference between Descartes' leaning toward mechanism in science and super-

naturalism in philosophy is readily intelligible as an instance of that distinction between the two spheres of knowledge, the natural and the supernatural, which was a familiar Catholic tradition traceable to Albertus Magnus and Thomas Aquinas. (*See* DESCARTES; CARTESIANS; KNOWLEDGE, THEORY OF; PSYCHOLOGY, HISTORY OF.)

Hobbes (1588–1679) shared Descartes' respect for mathematics and for deduction, as against the empiricism of Bacon. But, unlike Descartes, he was opposed to supernaturalism, and whereas Descartes confined mechanical explanations within the limits of material nature, Hobbes applied it everywhere, to the mental as well as to the material. The result was a materialistic philosophy. Matter and motion are the only ultimate realities, and explain everything, even knowledge. For all knowledge is derived from sense. "There is no conception in a man's mind, which hath not at first, totally or by parts, been begotten upon the organs of sense." And the sense experiences are produced by the several motions of the matter pressing on the sense organs. "Neither in us that are pressed are they anything else but divers motions; for motion produceth nothing but motion" (*Leviathan*, I., i.). For Hobbes mind is matter, and thought, like every process or change, is motion—"all mutation consists in motion." And the same fundamental tendency characterizes all beings, whether human or not, namely, the tendency to persist in their present condition, whether of motion or of rest. Hobbes does not deny the existence of God. The search for the cause of an effect, and for the cause of that cause, and so on, leads to the thought of an ultimate eternal cause or God; but we "cannot have any idea of him." The chief work of Hobbes belongs mainly to the history of ethics and of political philosophy. (*See* HOBBES; MATERIALISM; ETHICS, HISTORY OF.)

Spinoza (1632–1677) marks the culmination of the various tendencies of the Renaissance. He vindicated the autonomy of reason against every kind of authority, subordinating even the Scriptures to it. Rationalism expresses itself most characteristically in the attempt to connect things in continuous series or systems of events which suffer no arbitrary incursions from outside in the form of supernatural interventions. The great achievements of that classic age of science were essentially expressions of the rationalism of the 17th century. Yet the rationalism of all the great scientists of the time was fragmentary, one-sided; it was a week-day rationalism handicapped with a Sunday irrationalism. Spinoza was the complete rationalist, the prince of rationalists. He attempted to interconnect the *whole* of reality in *one* organic cosmos, which suffered no cleavage into a natural and a supernatural realm, or into a work-day and a Sabbath vista. For Spinoza, the world is a real universe. It is also a real cosmos, orderly through and through, subject to no arbitrariness, not even the arbitrariness of God. The rejection of the supernatural and the arbitrary constitutes the naturalism of Spinoza. But his conception of the universe avoided sacrificing any one part of it to any other, of the material to the mental, or vice versa. While repudiating any reality outside the cosmos (or Nature) he was careful to include within it whatever could claim reality—not only the material and the mental, but also the divine. They all have their place in the cosmic system. In fact God is the cosmic system. For God is conceived as the Perfect Self-existent; and that is just what the cosmos or Nature is—hence *Deus sive Natura*. The All is God, and God is All. This constitutes the pantheism of Spinoza.

The way in which Spinoza arrived at his main conceptions is rather obscured by the geometric method of exposition pursued in his *Ethics*. Briefly it was this. To understand any finite object or event it is necessary to follow up innumerable conditions on which it depends. These ramify in all directions, yet we can never halt, for the conditions invoked are themselves dependent on innumerable others. But a world consisting *entirely* of dependent objects and events would be unintelligible, inconceivable. There must be some unconditioned, self-dependent, absolute reality, or Substance, to account for the reality of all that is conditioned and dependent. This is usually admitted. But the traditional solution, accepted by Descartes and the greatest scientists of the 17th century, was that God, a supernatural omnipoten Being, is this self-existent, absolute Being or Substance, who ha created all things and maintains them. But the idea of an extern Creator did not satisfy Spinoza. His rationalism revolted agains the arbitrariness implied in the creation having taken place at on time rather than another; nor could it find in the notion c creation out of nothing anything more intelligible than the prob lems it was intended to solve. If it is necessary to posit a absolute ground of reality, why not accept the system of realit itself as this self-dependent substance?

This view avoided the unnecessary multiplication of entitie and the difficulties of creation out of nothing. It was also mor satisfactory to the religious side of Spinoza's character, for brought man into more intimate relation with God. Such a vie was, of course, only possible in consequence of the friendlie attitude towards Nature which the Renaissance cultivated, a against the hostile association of "the world, the flesh and th devil" characteristic of mediaeval Christianity. With regard t the structure of the cosmic system, the leading ideas of Spinoz may be summarized as follows. God (or Nature or Substance) not static but dynamic, and exercises all the kinds of energy th there are. It alone is absolutely infinite or absolutely perfec Each kind of energy that is ultimate, that is, irreducible to an other kind, Spinoza calls an attribute of substance. Spinoza refe to an infinity of such attributes. But by "infinite" he mean "complete" (not innumerable) and by "finite" incomplete c fragmentary. Man only knows two such attributes, namely e tension and thought, that is, physical energy and mind energ There may be others; there probably are. Moreover, each attr bute is *infinite of its kind*, that is, exhausts everything of its ow kind, so that there is no physical energy outside extension, nc mind energy outside thought.

All finite bodies and physical events are "modes," that is, mod fications or states, of extension, and all minds and mental e periences are modes of thought. Similarly with the other attr butes, if any. All cosmic activities or processes are immanen not transcendent. And all apparent interactions between the mod of different attributes, say that between the body and soul c man, result from the fact that they are concomitant expressior of the attributes of the one substance. "The order and connectic of thoughts is the same as the order and connection of things. Physical effects should be traced to physical causes, and ment experiences to mental causes. The various finite modes com into being and pass away; but not into nothingness—for the Or remains in which the many change. God as conceived by Spinoz is not a "personal" God, not however because He is less, bu because He is infinitely more than any personality known to ma (*See* SPINOZA; PANTHEISM; ETHICS, HISTORY OF; KNOWLEDG THEORY OF.)

Leibniz (1646–1716) was influenced mainly by his faith i the permanent reality of individual souls. His philosophy, accor ingly, is so constructed as to secure the ultimate reality of i dividuals, and to assure their permanence. To this end two thin were felt to be necessary. He had to dissociate souls fro physical atoms, and to treat each individual soul as a kind c "substance," or self-contained thing. The Cartesian identificatio of matter with extension (which was widely accepted then prompted Leibniz to deny the reality of matter altogether. F matter is then infinitely divisible, and no real "atom," nothir ultimate and really indivisible, can be conceived for the co struction of the composite bodies of ordinary observation. Fro this he concluded that all space or all material bodies are me subjective appearances, not objective realities. Reality, accor ing to Leibniz, consists entirely of souls or spirits of all degre of development. These are the real "atoms" or "individuals real unities not made up of parts. Some of them have only a ve low degree of consciousness or sub-consciousness, they are in state of chronic somnolence, so to say; some are in something li a dream state; others are more awake, have clear thoughts, are even self-conscious; and God, the "monad of monads" supremely conscious and active. There is an infinity of monad their gradation is continuous, without a break; and no two a

exactly alike.

To avoid the tendency to pantheism, Leibniz regarded the monads as not interconnected in any way, as incapable of influencing one another—"they have no windows by which anything can come in or go out." But there is one important exception to this, for God has created all other monads, which are "emanations" from the monad of monads. This, of course, makes the supreme monad different in *kind,* not merely different in *degree* from the other monads. However, having conceived the monads as "without windows" Leibniz has now to explain the appearance of interaction between them—the apparent interaction, *e.g.,* between the assembly of less developed monads which look like a body and that higher monad which is the soul. The problem is very like the problem which confronted the Cartesians, and the solution offered by Leibniz is rather like occasionalism. The ordinary monads do not really interact; each is self-contained, and develops from within, its present being pregnant with its future. But God has so made them all that they act in harmony. It is as if He had wound up so many clocks to keep time together. There is thus a "pre-established harmony" in consequence of which also each monad may be regarded as mirroring the entire universe, or every other monad, from its own point of view.

Like Descartes, Leibniz also follows strictly mechanical methods in dealing with physical problems, but he conceives mechanism to be in the service of teleology, and his general outlook, of course, was essentially teleological. His conception of the relation between the supreme monad and the other monads is obviously supernatural. In his philosophy, as in his public activities, Leibniz tried to bring together too many different elements to succeed in unifying them in one system. Leibniz is also famous for his optimism, that is, for holding the view that the actual world is "the best of all possible worlds." What he meant was that the "pre-established harmony" actually established by God was chosen by Him as the best possible, out of an endless variety of possibilities, in view of the purpose which He had in view. This does not imply that each thing regarded by itself is the best of its kind, or even good. It means only that in order to make any one thing better, the entire scheme of things would have to be different, and, as a whole, rather worse. (*See* LEIBNIZ; IDEALISM; KNOWLEDGE, THEORY OF; OPTIMISM.)

FROM LOCKE TO HUME

Locke (1632–1704) has the distinction of having given a decidedly epistemological turn to modern philosophy. He relates that five or six friends used to discuss philosophical or theological problems with him, but fruitlessly. So it occurred to him "that before we set ourselves upon inquiries of that nature, it was necessary to examine our own abilities, and see what objects our understandings were or were not fitted to deal with." By "extending their inquiries beyond their capacities" people only "raise questions and multiply disputes, which, never coming to any clear resolution, are proper only to continue and increase their doubts, and confirm them at last in perfect scepticism." Locke attempted to carry out the task which he set himself by means of a descriptive account of human "ideas" or experiences, of which he drew up a detailed inventory in his *Essay concerning Human Understanding* (1690). Locke uses the term "idea" for any "object of the understanding," any object as experienced; and, directly or indirectly, he traces all ideas to experience. This constitutes his empiricism. He rejects innate ideas, maintaining that prior to experience the mind is like a blank paper; but he credits the mind with certain powers. Ideas are of two kinds in respect of their origin. Some are induced by sensible objects—they are "ideas of sensation." Others result from reflection upon such ideas of sensation—they are "ideas of reflection." And the mind not only reflects, but also combines the given simple ideas into complex ones.

Locke believes that there are external things. But the mind does not apprehend them directly; ideas of sensation are at best only "appearances" of things, only copies of them, mediating between them and the apprehending mind. And this is true only of ideas relating to primary qualities (extension, figure, number, motion, solidity); the ideas of sensation relating to secondary qualities (colour, smell, etc.) are simply secondary or subjective effects produced in us by the primary qualities, and are not copies of anything objective. By combining the simple ideas of sensation and reflection there result complex ideas of substances, modes (*i.e.,* states of substances), and relations. The idea of a substance, or substratum, supporting qualities, etc., corresponding to simple ideas, Locke regards as an invention—he cannot trace it to a simple idea of experience, and he admits that it is vague. Yet he accepts the reality of substances, both physical and mental substances.

Of his own existence, each man is absolutely sure, by intuition; he cannot even doubt it without presupposing it. Of God's existence we are also certain, by demonstration; for our own existence cannot be explained without reference to Him as its cause. But, all the same, the "real essence" of substances is unknowable, and Locke is "apt to doubt a science of physical bodies as out of our reach" beyond merely empirical limits. (*See* LOCKE; EMPIRICISM; KNOWLEDGE, THEORY OF; PSYCHOLOGY, HISTORY OF.)

Berkeley (1685–1753) set himself the task of opposing the mechanistic methods of explanation generally accepted in his time in consequence of the fashion set by the great pioneers of modern science. He feared that that way lay materialism and atheism. But it was Locke's *Essay* that served him chiefly as the text of his criticism, especially in his *Principles of Human Knowledge* (1710) and the *Three Dialogues* (1713). Locke had maintained that our ideas of primary qualities resemble their external objects, whereas those of secondary qualities have no corresponding objects. Berkeley objected that both kinds of ideas are equally dependent on the mind and there is no more need or justification to assume the objective existence of primary than of secondary qualities. Moreover it is absurd to suppose that an idea can resemble anything that is not an idea. And if it is superfluous to assume the objective existence of primary qualities corresponding to certain ideas of sensation, it is even more unnecessary to assume, with Locke, the independent existence of material substance, of which, strictly speaking, we have no idea at all.

Locke had treated ideas of sensation as things which mediate between the knowing mind and corresponding material objects which they resemble where there is real knowledge; but Berkeley denounces this distinction between ideas and external objects as "the very root of scepticism"—"for how can it be known that the things which are perceived are conformable to those which are not perceived?" (*Principles,* 86). For Berkeley the ideas are the objects of knowledge, and there is nothing beyond them. "All the choir of heaven and furniture of earth, in a word all those bodies which compose the mighty frame of the world, have not any substance without the mind; . . . their *being* is to be perceived or known . . . consequently so long as they are not actually perceived by me, or do not exist in my mind, or that of any other created spirit, they must either have no existence at all, or else subsist in the mind of some Eternal Spirit" (*Ibid.* § 6). With the substantiality of matter its causality is also rejected. One idea of sensation cannot *cause* another; it can only *suggest* it. "The fire which I see is not the cause of the pain I suffer upon my approaching it, but the mark that forewarns me of it" (*Ibid.* § 65). And if one asks how it comes about that there appear to be such regular connections between divers ideas, the answer is "that this is done in virtue of an arbitrary connection instituted by the Author of Nature" (*Theory of Visual Language,* § 43). For spirits or minds are active agents, in fact the only ones.

Mechanistic explanations are therefore illusory. And if one objects (as Hume did soon afterwards) that there seems to be no more reason for assuming a mental substance than a material substance, ideas being the only things known, then Berkeley's reply is as follows: "I *myself* am not ideas, but . . . a thinking, active principle that . . . operates about ideas. I know that I . . . perceive both colours and sounds: that a colour cannot perceive a sound, nor a sound a colour: that I am therefore one individual principle, distinct from colour and sound, and . . . all other sensible things or inert ideas" (*Third Dialogue*). He admits, however, that he has no "idea" of minds or spirits, only a

"notion." Anyway the net result of Berkeley's speculations is an idealist philosophy according to which the only realities are God, other spirits or minds which He has created, and the innumerable ideas which He has produced and arranged for us to apprehend in certain sequences arbitrarily decreed by Him. (*See* BERKELEY; IDEALISM; KNOWLEDGE, THEORY OF.)

Hume (1711–1776) pursued the problems and methods of Locke to their extreme conclusion, in the sense that he showed that the kind of empiricism which Locke had advocated leads to positivism in science and scepticism in philosophy. It is one of the ironies of history that the book which Berkeley wrote in order to prevent or to cure scepticism actually infected Hume with it. "He professes [so writes Hume of Berkeley] in his title-page . . . to have composed his book against the sceptics as well as the atheists and freethinkers. But that all his arguments, tho' otherwise intended, are in reality merely sceptical, appears from this, that they admit of no answer and produce no conviction. Their only effect is to cause that momentary amazement and irresolution and confusion, which is the result of scepticism" (*Enquiry Concerning Human Understanding,* section 12, part i.n.). Berkeley had contended that there is not sufficient evidence for assuming material substances or material causality, as we have no ideas of either; but he defended both the substantial nature and causal power of minds or spirits. Hume argued that the same reasons which led Berkeley to reject material substances and material causes are also valid against the assumption of mental substances and mental causes.

Berkeley had tried to save mental substances and mental agency by pleading that we have "notions" of them apprehended by reason, though not "ideas" of experience. But Hume rejected this view of a radical distinction between "reason" and "experience," and submitted everything, even rational judgments, to the test of experience, and insisted on accounting for everything in terms of experience. He accordingly denied the certainty even of so-called mathematical knowledge, and reduced all alleged knowledge or certainty to mere probability. Causality itself he explained away as habitual association of sequent impressions or ideas; and substances as due to the mistaking of similar, recurring impressions for continuous impressions of the same thing. (*See* HUME; KNOWLEDGE, THEORY OF; SCEPTICISM.)

FROM KANT TO HEGEL

Kant (1724–1804) is the founder of the "critical" philosophy or of "transcendentalism." The stress which Descartes had laid on thought, or subjective experience, in basing his whole system on the *cogito ergo sum,* quite naturally resulted in a divorce between ideas, on the one hand, and the external world on the other. This is clear alike in the idealism of Leibniz and Berkeley, in the empiricism of Locke, and in the scepticism of Hume. The only philosophers of importance who avoided this predicament were Spinoza, on the one hand, and Thomas Reid (1710–96) and the Scottish school, on the other. But the alleged atheism of Spinoza robbed him of real influence; and the "common-sense philosophy" of the Scottish school was not sufficiently subtle to impress speculative minds. Kant attempted a new way of bringing thought and reality into touch once more. Kant himself liked to stress the "critical" character of his philosophy as the new element which he contributed; and consequently called his three great works *critiques.* He described all his predecessors as "dogmatic" philosophers, because they did not begin their philosophy with a critical examination of human capacity for knowledge.

The way in which Kant attempted to reunite knowledge with reality was briefly as follows. Known objects, according to Kant, are a multiplicity of sense-materials supplied to the apprehending mind which synthesizes them in accordance with certain forms of intuition (space and time) and certain categories of thought (substance and attribute, cause and effect, etc.). What the multiplicity of sense-materials may be before the mind has synthesized them, we do not and cannot know. But they are not produced by the mind, they are only apprehended and moulded by it—they are or pertain to "things-in-themselves." On the other hand, the forms of intuition and the categories of thought are ways in which the mind in virtue of its own nature moulds or systematizes the multiplicity of disconnected sense-materials so as to adapt them to its own unity. These forms are *a priori* or "transcendental" in the sense that they are not derived from experience, inasmuch as experience itself would be impossible without them; on the other hand, the multiplicity of sense-material is *a posteriori,* only given in experience and known through it (though not known "in itself").

These various *a priori* forms of apprehension are not peculiarities of the unity of individual minds as such, but rather express the unity of "consciousness in general" in which individual minds participate, but which is "super-individual." That is how it comes about that there is universal agreement in the use of the *a priori* forms and categories, instead of individual variations. Anyway, human knowledge does not extend to the intrinsic nature of ultimate reality or "things-in-themselves" but only to their appearances as moulded by the forms of intuition and categories of thought. In Kant's language, human knowledge is of "phenomena" not of "noumena" or "things-in-themselves." And any attempt to apply the *a priori* or "transcendental" forms to what does not fall within the realm of possible human experience, Kant condemned as "transcendent." The existence of God, and the immortality of the soul, *e.g.,* are beyond the realm of possible human experience, and therefore of knowledge though what cannot be *known* may yet be *believed* as a matter of *faith.*

And it is on such "practical reasons" that Kant based the beliefs in the existence of God, in the freedom of the will, and in the immortality of the soul. These things, according to Kant, are postulates of morality. The "categorical imperative," the unconditional character of the sense of duty, can only be understood and justified on the assumption or faith that we are free to do, or "can" do, what we "ought" to do, that there is a God who can duly correlate virtue with happiness, and that there is a hereafter in which the injustices of the present life may be adjusted. Kant's moral philosophy brings out with special clearness a striking feature of his whole method of philosophizing. He does not doubt the validity of the sense of duty or the "categorical imperative"; he acknowledged it, and only draws out its implications or conditions. Similarly, Kant did not question the reality of the external world as conceived by contemporary (Newtonian) science; he accepted it (as Hume the sceptic would not), and tried to elicit the conditions of the validity of that science. (*See* KANT; ETHICS, HISTORY OF; KNOWLEDGE, THEORY OF; TRANSCENDENTALISM; RATIONALISM.)

Fichte (1775–1854) agreed with Kant in ascribing to mind or "consciousness in general" (or "absolute self" as he preferred to call it) the forms of intuition and categories of thought which characterize objects of knowledge. But he held that Kant had not gone far enough. Kant had recognized "things-in-themselves" or "noumena" independent of consciousness, and furnishing the sense-materials for experience. These "noumena" could only be vaguely thought about, not perceived, except as moulded in the forms of knowledge, supplied by consciousness. Fichte, however, held that even the "thing-in-itself" is also the product of consciousness. The "absolute self" (in which individual minds participate) is the source of the whole of experience, not of its forms only. It divides itself in experience into a knowing self and a known object, because the development of the moral life needs objects as obstacles to be overcome by moral effort prompted by a sense of duty. Moreover, there must be many minds or selves, if there are to be mutual duties. But they are all the expressions of one moral order, which is the "absolute self" or God. (*See* FICHTE; IDEALISM.) A philosophy essentially like that of Fichte was taught subsequently by R. Eucken (1846–1926).

Schelling (1775–1854) reverted more or less to the fundamental conception of Spinoza, and tried to vindicate the reality of the material against the efforts of so many modern philosophers to reduce it to mere appearances or ideas. He contended that the beauty of the material world (or Nature, in the narrower sense of the term) gave it a sufficient claim to have a reality of its

own. So he conceived of Nature as an expression or manifestation of the Absolute in the same way as consciousness or mind is. Nature and mind are thus conceived to be related to the Absolute in the same kind of way as the two attributes, extension and thought, were conceived by Spinoza to be related to substance. The Absolute, however, came to be conceived as being in itself neither material nor mental, but something common to both or identical in both. Hence the name "identity philosophy" by which Schelling's system is commonly known. (*See* SCHELLING; IDEALISM.)

Hegel (1770–1831) is the founder of logical Idealism or Panlogism. He rejected the unknown "thing-in-itself" of Kant and the equally unknown "identity" or Absolute which, according to Schelling, manifests itself in Nature and mind He denied the opaqueness of ultimate reality and insisted that the entire universe "can be penetrated by thought." Mind and Nature are not merely manifestations or expressions of an otherwise unknown Absolute; they are the Absolute itself. Moreover, mind and Nature, according to Hegel, are not two distinct or parallel realities but integral components of one process of self-revelation. Mind needs for its own development an objective world, or Nature, on which to exercise itself; but this objective world is itself mental, something that is at once appearance and reality—"the real is rational, and the rational is real" The development of this rational reality is a kind of dialectic proceeding by the method of thesis, antithesis, and synthesis, or position, negation and reconciliation Some thought occurs: it is opposed by another thought, which also turns out to be inadequate; but what is true in each, the thesis and the antithesis, is harmonized and made mutually supplementary in another thought which synthesizes them; *e g.*, "becoming" is such a synthesis of "being" and "not-being"

The whole world, according to Hegel, is made up of such opposites which are reconciled The general scheme of the cosmic dialectic is this First comes "mind in itself," or the system of categories, which are conceived by Hegel, not as mere forms of thought by which unknown things-in-themselves are apprehended, but as ultimate realities; next comes "mind for itself," that is Nature as the self-externalization of "mind in itself"; lastly, comes "mind in and for itself," that is, mind or consciousness coming or returning to itself This last phase, the mind's coming to itself, has a number of grades or stages These are: individual mind or subjective consciousness; objective mind or social consciousness as expressed in law, morality, the State; and absolute mind or consciousness active intuitively in art, imaginatively in religion and intellectually in philosophy. Hegel's conception of the cosmic process as a rational dialectic stimulated new views of history and, consequently, a new interest in it. (*See* HEGEL; KNOWLEDGE, THEORY OF; IDEALISM.)

GERMAN PHILOSOPHY SINCE HEGEL

Materialism.—Various influences combined to occasion a tendency towards materialism about the middle of the 19th century Idealism had on the whole sided definitely with conservatism in religion and politics. Hegel's dictum, "the real is rational," was readily exploited in a reactionary sense beyond anything that Hegel intended, conservative as he himself had been. The generation inspired by the revolutionary tendencies of 1848 resented this kind of idealism. Stimulated by the microscopic biology of Schwann (who showed the cell to be the unit of plant and animal organisms), by the chemical researches of Liebig, by Schleiden's rejection of vitalism, and by the physical experiments of Mayer, Joule, Colding and Helmholtz, which resulted in the discovery of the principle of conservation of energy, the scientific spirit of the age revolted against the idealists' indulgence in romantic speculation. Industrial progress, advance in the technical arts, and the consequent improvement in economic and material conditions, also helped to stimulate special interest in things material. And the doctrines of the French materialists of the 18th century, La Mettrie (1709–51), Holbach (1723–89) and Cabanis (1757–1808), were ready at hand to be taken up and developed. J. Moleschott (1822–93) described the whole cycle of life in terms of matter and energy. Matter conditions life, life conditions thought, and thought conditions the will to improve life. Physical conditions are the main determinants of human destiny.

K. Vogt (1817–95) supplemented Moleschott's dictum, "no sulphur, no thought," with the statement that "thought is related to the brain in the same way as bile is to the liver." The same thing had been said already by Cabanis. Vogt did not pretend to know how exactly the brain does produce thought L. Büchner (1824–99) was the most influential of this group, and his *Force and Matter* (1855) served for a considerable time as the source-book of materialism. He identified force of every kind with movement, and regarded everything as the product of matter and motion which are distinguishable but not separable. He rejected vitalism, held that life is spontaneously generated out of matter under certain conditions, and that mental process is only "a radiation through the cells of the grey substance of the brain of a motion set up by external stimuli" H Czolbe (1819–73) rejected everything supersensuous and all "transcendental nonsense." But he maintained that the world cannot be derived from any one principle, such as Buchner's "force and matter," but only from a plurality of irreducible principles, including material atoms, organic forces, mental elements, etc, which between them constitute an harmonious and purposive natural system. Like the other materialists in this group, he was inspired by an enthusiasm for humanity and the amelioration of human conditions. (*See* MATERIALISM)

Schopenhauer (1788–1860) is the philosopher of "voluntarism" and "pessimism" Just as Hegel, his senior contemporary, had identified ultimate reality with reason, so Schopenhauer, on the contrary, identified it with will, and irrational will to boot. He too, claimed to be developing the philosophy of Kant For Kant, like Descartes and others before him, had maintained the primacy of the will, on which the whole moral philosophy (including the moral postulates) was based Will, then, according to Schopenhauer, is the sole reality Moreover, it is universal, or "will in general" (analogous to the "consciousness in general" of Kant and the German Idealists) There are really no individual things or wills For individuality is bound up with differences of time and place, which had been shown by Kant to be not real constituents of things-in-themselves, but merely forms of their appearance Individuality is thus mere illusion Again, Schopenhauer, like Kant, agreed with the Christian view that the will is essentially evil It is a will to live at any cost, and knowledge or reason is merely an instrument which it has invented to serve its own evil ends. But there is no satisfying the will to live. All the pains taken to satisfy any desire do not really avail. For the satisfaction of any one desire is only the beginning of another, and the quest is infinite So life is a welter of painful strivings and unsatisfied cravings which vastly exceed its moments of satisfaction or happiness The remedy is a kind of Buddhist self-renunciation By realizing the illusoriness of the individual self and the vanity of its quest for self-satisfaction, man may see through the vanity of life with all its values and pursuits. (*See* SCHOPENHAUER; PESSIMISM)

Fechner (1801–87) developed the philosophy known as Panpsychism, that is, the view that the universe is a system or society of souls, of which God is the highest and all-comprehensive soul. According to Fechner material bodies are souls as they appear to other souls, whereas each soul as experienced from within is psychical In this way he tried to save the reality of matter as well as of mind in psychophysical entities of which they are the outer and the inner side respectively But he regarded the two sides as parallel without any interaction; and it was largely due to his influence that many psychologists adopted psychophysical parallelism as the working hypothesis in psychology. Fechner tried to combine pantheism with something sufficiently like the monadology of Leibniz to safeguard the interests of finite souls. He identified God with the soul of the universe, and regarded it as embracing all other souls just as larger bodies contain smaller bodies, and nature contains them all. (*See* FECHNER; PSYCHOLOGY, HISTORY OF)

Lotze (1817–81) elaborated a philosophy which may be

described as idealistic pantheism. In other words ultimate reality, according to him, is like Spinoza's substance, with thought (or consciousness) for its sole attribute. He agreed with Kant that all known things are merely sensible phenomena; but he rejected Kant's unknown "things in themselves." He agreed with Leibniz in regarding spiritual monads as the causes of material phenomena; but he rejected the view that the monads are substances. The monads, according to Lotze, are only modes or modifications of the one and infinite Substance, God. The interaction of the monads he reduced to the immanent causality of God, who is the sole real cause or agent. The mechanistic character of phenomena Lotze explained by saying that God carries out His immanent activities in accordance with uniform laws. These laws, however, are subordinate to divine ends, the system being teleological as well as mechanistic in part. Human souls, like other monads, are not substances, but modes or activities of the one Substance. Lotze repudiated the method of Hegelian idealism as unscientific. But he tried to save all such idealistic elements as he considered to be in harmony with science and human experience. (*See* LOTZE; LOGIC, HISTORY OF.) A philosophy essentially like that of Lotze was taught by James Ward (1843–1925) who had studied under him.

Hartmann (1842–1906) adopted and developed Schopenhauer's voluntarism and pessimism. For Schopenhauer reality is essentially will which produces knowledge or representation as an instrument for its satisfaction. For Hartmann, however, representation is on a level with, not subordinate to, will. Together they constitute the "unconscious," which is the "absolute" in his system. With the development of the unconscious its two components differentiate gradually, and the unconscious becomes conscious, even self-conscious, and realizes the tragedy of the will to live. The remedy is so to set the two components of the unconscious, will and representation, into mutual antagonism as to secure eventually their mutual annihilation and eternal peace from the restless and unsatisfying pursuits of life. (*See* HARTMANN.)

Nietzsche (1844–1900) was influenced chiefly by Kant, Schopenhauer and Darwin. He agreed with Schopenhauer's main theses but drew a different moral from them. Nietzsche, even more than Schopenhauer, so interpreted Kant's theory of knowledge as to deny the very possibility of knowledge, and to reduce all so-called knowledge to mere fiction or artistry. The human mind, in the very act of apprehending reality, transforms it. "Truth (says Nietzsche) is not something which is already there to be found or discovered; it is something which has to be created"—it is "man-made," as the Pragmatists said after him. This does not mean that he lumps all human beliefs together indiscriminately. Only in place of the usual distinction between "true" beliefs and "false" ones, Nietzsche would substitute the distinction between those which are "useful" and those which are not, but without in any way holding that the useful is true, even as a matter of probability.

The epistemological side of Nietzsche's philosophy was developed in the "fictionism" of Vaihinger's *Philosophy of "As If"* (1911, Eng. trans. 1926). Ontologically Nietzsche agrees with Schopenhauer in identifying all reality with will. "It is will that struggles for existence in animate and inanimate nature." For Nietzsche, however, this will is not merely a will to live, but a "will to power." "This universe is a monster of energy, without beginning or end." Nietzsche accepted "will to power" as ultimate reality because his experience convinced him of the reality of desires and impulses as of nothing else; and he considered these a sufficient guide to philosophical construction. Like Schopenhauer, he frequently paints the world in sombre colours. But the shortcomings of the world stimulate him instead of depressing him. And far from accepting Schopenhauer's ideal of a Buddhist saint, he regarded the world as a kind of Greek tragedy affording ample opportunity for heroes to show their mettle. Hence his gospel of energetic life, and his ideal of a "superman" who shall surpass the present type of man as much as man surpasses the ape. (*See* NIETZSCHE.)

Wundt (1832–1921) begins by insisting that human experience consists of ideas in which subjective and objective factors are inseparably combined. These factors may be distinguished by abstraction. And in physical science the objective factors, or objects, are so habitually abstracted that they come to be regarded as independent things. But this is an error, for "the whole world exists for us only in our ideas," and all that reason posits behind or beyond phenomena must be regarded as transcendent "ideals." Again, the basic reality in experience, "the most proper being of the individual subject," is will, though it is never entirely divorced from feeling and ideas. There are two grades of will, namely, impulsive will and voluntary will. Even impulsive will needs feeling directed to an end, and therefore an idea, but not conscious adoption of a motive, which pertains to voluntary will. He attributes impulsive will to all organisms, and consequently maintains that in organic evolution teleology precedes mechanism, final causes precede and originate mechanical or efficient causes. Wundt describes not only attention but also thinking as will. For it is activity, and all activity is will. (The conception of this "will to believe" was elaborated by William James.) Wundt, in fact, regards the soul as "activity," not substance—it is the entire mental activity associated with a system of bodily activities. The body itself is only an object distinguished by abstraction from the complete experience, of which soul is the subjective factor. There is consequently no psychophysical opposition or interaction, only a psychophysical parallelism. Human knowledge is limited to experience, or phenomena, or ideas. Reason does indeed transcend experience. But it can only posit "ideals," which are matters not of knowledge but, at most, matters of faith. One such "ideal" is God, conceived as the world-will. (*See* WUNDT; PSYCHOLOGY, HISTORY OF.)

Neo-Kantianism.—The attempt to correct at once the materialism of the time and the absolute idealism which had partly provoked it led to a revival of interest in the philosophy of Kant and a concentration on the problems of knowledge. The movement was initiated by O. Liebmann (1840–1912). In his book *Kant und die Epigonen* (1865) every chapter ends with the refrain, "we must therefore return to Kant." F. A. Lange (1828–75) advanced the movement by means of his *History of Materialism* (1866) in which he attempted to refute materialism by means of arguments based on Kant's theory of knowledge and its repudiation of all knowledge of the ultimate nature of reality, or things as they are in themselves. He insisted that the "matter," "atoms," "forces," etc., by means of which materialists try to account for all things, are not ultimate realities but only auxiliary conceptions of science. In 1871 H. Cohen (1842–1918) published his book on *Kant's Theory of Experience*, and soon became the leader of the whole movement. He was joined by P. Natorp (1854–1924), his colleague in the University of Marburg, where Lange too had been professor, and the movement consequently came to be known as "the Marburg School" of philosophy. The chief representative of Neo-Kantianism at present is E. Cassirer (1874–). It cannot be said that the Neo-Kantians are agreed on all points. Far from it. What is common to them is the recognition of the importance of understanding Kant and developing his transcendental method. Cohen in particular attempted to do without Kant's aesthetic, to dispense with the assumption of a given sense material, and to begin at once with the transcendental logic. There is no object then to be known; what becomes known only becomes an object in becoming known. Nothing is independent of thought. For thought and being are identical, and the judgment is the unit of both. (*See* NEO-KANTIANISM.)

POSITIVISM AND EVOLUTIONISM

Comte (1798–1857) was the founder of "Positivism," that is, the view that knowledge is limited to the objects of direct observation or experience. This view is very like the empiricism of Locke and his successors. Comte's positivism, however, was the outcome rather of the influence of Kant's philosophy, according to which human knowledge (as distinguished from faith) is limited to phenomena, and cannot penetrate to noumena or things-in-themselves. What is beyond experience, Comte insisted, is unknowable. It is consequently best to concentrate on tasks

that are within human competence. Such are the pursuits of the sciences and the work of social amelioration. Philosophers, instead of their search for an unknown and unknowable Absolute, should devote themselves to the task of co-ordinating and systematizing the methods and results of the positive sciences. Religion, instead of being the worship of an unknown God and a source of division, sectarian conflict and hatred, should be identified with the service of the cause of mankind—a religion of Humanity. And humanity should be so improved by collective endeavour that it shall become worthy of being viewed as "the great Being," the object of religious service. What Comte had in mind was a grandiose Catholicism without religion, as religion is commonly conceived. Positivism, Comte realized, is a position not readily taken up. First in the history of intellectual growth, comes the theological point of view, and everything is explained by reference to one or more gods who are created in the likeness of men. Next comes the metaphysical stage in which the anthropomorphic Gods are more or less dehumanized and replaced by abstract entities or principles. Then only comes the positivist stage. But even Comte was not a strict positivist. For he severely criticized the actual state of mankind, and pleaded for various reforms according to standards derived, not from observation, but from ideals. (*See* COMTE; POSITIVISM.)

Mill (1806–73) also may be called a positivist. But in his case the connection with British empiricists is more marked than in the case of Comte. His logic, his utilitarian ethics, and his political economy are all worked out on empirical or positivist lines. (*See* MILL; LOGIC, HISTORY OF.)

Spencer (1820–1903) admitted an ultimate reality as the ground of the phenomenal world, but regarded it as otherwise "unknown." Inasmuch as he confined knowledge to phenomena, he was a positivist. But his fame rests mainly on his comprehensive attempt at an evolutionary philosophy which brought or forced "all the choir of heaven and furniture of earth" into the evolutionary scheme. The conception of evolution was not new to philosophy. Hegel's philosophy was evolutionary in a sense; but not quite in Spencer's or Darwin's or generally in a scientific sense. According to Spencer the universe commenced as an homogeneous something, which may be called force, or matter and motion, but the inner nature of which is unknown to us. Then by increasing differentiation and specialization there evolved the heavenly bodies (more or less in accordance with the nebular hypothesis of Laplace); the inorganic evolved into the organic (more or less on the lines of Lamarckian and Darwinian biology); differentiation of structure and function in living bodies, and division of labour in industry, etc., followed in due course. And always the amount of energy remains the same in accordance with the principle of Conservation of Energy; it is only redistributed in various ways. The evolutionary process as conceived by Spencer and others was mechanistic in character. This conception subsequently met with increasing opposition. In contemporary philosophy Bergson's theory of "creative evolution" and Lloyd Morgan's theory of "emergence" or "emergent evolution" are intended as a corrective of mechanistic determinism in favour of spontaneity and originality in cosmic processes of many kinds. (*See* SPENCER; ETHICS, HISTORY OF; EMERGENCE; EVOLUTION AND MIND.)

RECENT AND CONTEMPORARY PHILOSOPHY

Neo-Hegelianism.—Until comparatively recently, British philosophy pursued its own course in almost entire independence of Continental philosophy. Its most characteristic feature was its initial empiricism, though it ended variously in agnosticism, scepticism or even in idealism. When the widespread influence of Kant's critical philosophy asserted itself, it was still used mainly to supplement the agnostic tendencies of native empiricism. In view of Kant's own indebtedness to Hume, this was not unnatural. Anyway, Kant's denial of the possibility of knowledge of things as they are in themselves, and its limitation to phenomena could readily be identified with Locke's and Hume's denial of our knowledge of "substances" and its restriction to "ideas."

The philosophical agnosticism of Hamilton (1788–1856), Mansel (1820–71), Spencer and Huxley (1825–95) may thus be regarded as betraying Continental influence only to a slight extent. The influence of German voluntarism was no greater, probably rather less. Martineau (1805–1900) was probably the only one in his generation to identify God, or the ultimate cause of the universe, with Will. The influence of German Absolute Idealism, however, was much more marked, especially in the logical form in which it was developed by Hegel. It cannot be asserted that Hegelianism had actual followers in England or in America. But Hegelianism harmonized well with the growing revolt against empiricism, and so some of the acutest thinkers in both countries were influenced by it sufficiently to be commonly described as Neo-Hegelians. The most important representatives of the group were Green (1836–82), Bradley (1846–1924), Bosanquet (1848–1923), Haldane (1856–1928) and McTaggart (1866–1925) in England, and Royce (1855–1916) in America—to say nothing of the many well-known representatives who are happily still living. Considering the logical or rational character of Hegel's idealism, it is natural to find that at least two of the Neo-Hegelians have made most important contributions to logic, which they treated in a highly epistemological manner (Bradley's *Principles of Logic,* and Bosanquet's *Logic*). Neo-Hegelianism is essentially a metaphysic of logical coherence, involving a doctrine of varying grades or degrees of reality. Reality, according to Bradley, is in the last resort a system of experience. The finite as such is not illusory, yet not absolutely real, only relatively so: it is entirely dependent upon, and rests within, the Absolute, or entire system of experience. In the broad sense in which the term Neo-Hegelian is here used it may also be applied to the two Italian philosophers, Croce (1866–   ) and Gentile (1875–   ), the Dutch philosopher Bolland (1854–   ), and the German Volkelt (1848–   ). (*See* NEO-HEGELIANISM.)

Pragmatism as a method of evaluating ideas by their practical consequences was formulated by C. S. Peirce (1839–1914) in 1878, and developed more fully by W. James (1842–1910), J. Dewey (1859–   ) and F. C. S. Schiller (1864–   ). The movement is based partly on psychological considerations, and partly on a dissatisfaction with the intellectualism and deterministic monism of absolute idealism. "Thinking," according to James, "is first and last and always for the sake of doing," and "the conception with which we handle a bit of sensible experience is really nothing but a teleological instrument." The agnostic or relativist side of Kant's teaching, as developed by Nietzsche and Vaihinger in some ways encouraged the substitution of the practically useful for the theoretically true as the standard of value for beliefs. And German voluntarism tended in the same direction. "The 'true,'" according to James, "is only the expedient in the way of thinking, just as the 'right' is only the expedient in the way of behaving." In the circumstances, it was natural that the effort at self-preservation characteristic of finite individuals should express itself in favour of a belief in the ultimate reality and worth of a plurality of finite beings, as against their merely relative being and worth in a monistic "block-universe." Hence the combination of pragmatism with pluralism. (*See* PRAGMATISM; PLURALISM; TRUTH.)

The New Realism.—In Germany it was idealism that provoked materialism, and materialism occasioned that revival of epistemological interest which produced Neo-Kantianism. With British and American philosophy the case is rather different. It was the materialistic tendencies of empiricism, agnosticism and evolutionism that provoked the idealism of the Neo-Hegelians, and the new realistic tendencies in epistemology have come as a revolt against idealism generally, and subjective idealism more particularly. The present movement was started mainly by G. E. Moore and B. Russell, and has been taken up eagerly by many others in Britain and in America. These thinkers differ in their views in some respects, but they agree in their endeavour to vindicate the independent reality of the objects of human knowledge, and especially of the objects apprehended in perception. (*See* KNOWLEDGE, THEORY OF.)

Bergson (1859–) is the founder of what is variously known as the philosophy of change, of creative evolution, or of duration. Like so many idealist philosophers, his main aim is to vindicate the spiritual principle in nature and freedom in human nature against the mechanistic tendencies of modern science. Somewhat like Fichte he conceives of ultimate reality as something less determinate than consciousness or matter, but from which both consciousness and matter are derived. This ultimate reality is an incessant flux, a creative evolution, or real duration. It is not an inaccessible absolute; it can be apprehended by man. "In the absolute we live and move and have our being. The knowledge we possess of it is incomplete, no doubt, but not external or relative. It is reality itself, in the profoundest meaning of the word, that we reach by the combined and progressive development of science and philosophy." Materiality and spirituality are resultants of processes in opposite directions. Spirituality is the process of concentrated activity in which the past interpenetrates the present; materiality corresponds to a relaxation of this activity.

The evolution of life has taken three divergent directions, the vegetative, the instinctive, and the intelligent or rational. These are not successive stages, but divergent lines of evolution. Instinct is a faculty of using organic instruments; intelligence is a faculty of making and using inorganic tools. Instinct is a kind of unconscious practical knowledge of things; intelligence is conscious thought about relations. Owing to its original function of making tools out of inert matter, intelligence when it develops its theoretical side tends to regard the whole of reality as though it were a dead mechanism. This can be corrected by means of intuition, which is instinct become self-conscious and capable of reflecting upon its objects. It is the function of philosophy to seize, expand and unite such fleeting intuitions which reveal the spiritual life. But intuition must not be divorced from intellection, nor science from philosophy. They must be brought into close relationship if we are to avoid chill mechanism, on the one hand, and illusory mysticism, on the other. For Bergson, not perception but memory is typical of the spiritual or conscious. Perception is simply incipient or nascent action, not consciousness. Memory is real duration, in which the past "gnaws into the future." (*See* Bergson.)

B. Croce (1866–) sets out from the Cartesian, or rather Augustinian, contention that thought is what we are most sure of, and then proceeds, like the German idealists, to maintain that it is the only reality that need be assumed. By thought, however, he does not mean merely the thought of finite individuals. Like most idealists he posits a universal mind which is more than any finite individual thoughts can be but which is immanent in them. And whereas Hegel conceived of the dialectic of universal thought as essentially logical in character, though he could not avoid conveying the impression that he also regarded it as a process in time, Croce definitely conceives the cosmic thought process as a process in time, and identifies reality or philosophy (for the two are essentially the same in such an idealistic scheme) with history. Like Bergson and James, Croce rejects the conception of a static, unchanging Absolute, a "block universe" complete once for all. Ultimate reality, as he conceives it, is incessantly changing, ever active, always creative. This cosmic activity has no beginning and no end, but proceeds in cycles. The objects to which thought is always directed are themselves the creations of thought. In fact, the process of thinking, the object of thought, and the distinction between the act and the object of thought, are all of them parts of the same total experience, and it is only by a kind of abstraction that a world of objects is set up as an independent world over and against the world of thought.

In reality the whole universe is just Mind or Spirit, and all differences and distinctions are within it. Of the activities of mind there are two main types, namely, theoretical and practical activities. Theoretical activity is of two principal varieties, namely, intuition and conception. Intuition is the act of creating the materials of thought, and is exemplified most clearly in the creative imagination of the artist. There is no sense material supplied to the mind from outside, according to Croce; the mind just has intuitions which constitute the material on which conceptual thought operates. Conception or conceptual thinking is the activity which creates and traces relations between intuitions. But the two, intuition and conception, are only distinguishable, not separable. Intuition without conception would be blind; conception without intuition would be empty. The practical activities are all of them volitional processes or functions, for there can really be no "physical" activities in a purely spiritual universe. And like the theoretical functions they also have two aspects or components, namely, a particular or individual aspect and a universal aspect, which are distinguishable but not separable. (*See* Croce; Idealism; Neo-Hegelianism.)

Alexander (1859–) is the first British philosopher to attempt a system of philosophy; and that after the prophets had confidently asserted that there would be no more system building in philosophy. His *Space, Time and Deity* (2nd ed., 1928) develops a philosophy which incorporates the new conceptions of space-time, and of emergent evolution, and leads up to a kind of pantheism not altogether unlike that of Spinoza. Ultimate reality is Space-Time, of which space alone and time alone are mere abstractions. Space-Time is a kind of ocean whose whirlpools constitute particular objects. Things, in other words, are differentiated complexes of motion within the one comprehensive system of motion. Space-Time has certain pervasive or "categorical" properties (existence, universality, relation, order, substance, quantity, number, motion, etc.) which characterize everything. Besides these there are various empirical qualities which distinguish different classes of objects, and which emerge only under special conditions. They form a hierarchy. What happens is this. Space-Time spontaneously differentiates into finite collocations of point-instants. The simples of these consist of motions of different velocities and extents of motion. When these objects form certain patterns there emerges the quality of materiality; when certain other conditions are added, there emerges colour; and so on.

When certain physico-chemical complexes arise, life emerges; out of certain configurations of living complexes consciousness emerges. In this hierarchy of objects, those that have the higher qualities also have the lower qualities. But they experience them differently—they "enjoy" their highest quality immediately and inwardly, but only "contemplate" the lower qualities more or less externally. By reasonable extrapolation we may assume that there are higher qualities than consciousness. And the highest of such conceivable qualities is "deity." As consciousness is the highest quality of man so "deity" is the highest quality of God, whose "body" is the whole universe. God is the whole universe as evolving the quality "deity." As time is never complete, higher qualities continue to emerge, and so God is never complete. The world with its nisus towards deity stirs in us a longing for God with Whom we are in communion. And practical religion consists in doing our duty so as to advance the progress of the world towards deity. The triumph of good over evil in human affairs is one of the conditions of the emergence of deity, and deity is on the side of goodness. The right attitude towards life is that of intellectual acquiescence coupled with practical efforts towards its amelioration, even though the springs of pain may never be sealed. As to the relation of the finite many to the infinite One, "the One is the system of the many in which they are conserved, not the vortex in which they are engulfed." (*See* Qualities, Primary, Secondary and Tertiary.)

PHILOSOPHY AND PHILOSOPHICAL STUDIES.

Philosophy is a general term whose meaning and scope have varied very considerably according to the usage of different authors in different ages. It can best be explained by a survey of the steps by which philosophy differentiated itself, in the history of Greek thought, from the idea of knowledge and culture in general. These steps may be traced in the gradual specification of the term. The earliest uses of the word (the verb φιλοσοφεῖν occurs in Herodotus and Thucydides) imply the idea of the *pursuit* of knowledge; but the distinction between the σοφός, or wise man, and the φιλόσοφος, or lover of wisdom, appears first in the Platonic writings, and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophon, and is doubtless to be attributed to the historical Socrates. But the word soon lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

A specific sense of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearances and the shows of sense. The philosophers, he says, "are those who are able to grasp the eternal and immutable"; they are "those who set their affections on that which in each case really exists" (*Rep.* 480). In Plato, however, this distinction is applied chiefly in an ethical and religious direction; and, while it defines philosophy, so far correctly, as the endeavour to express what things are in their ultimate constitution, it is not yet accompanied by a sufficient differentiation of the subsidiary inquiries by which this ultimate question may be approached. Logic, ethics and physics, psychology, theory of knowledge and ontology are all fused together by Plato in a semi-religious synthesis. It is not till we come to Aristotle that we find a demarcation of the different philosophic disciplines corresponding, in the main, to that still current. The earliest philosophers, or "physiologers," had occupied themselves chiefly with what we may call cosmology; the one question which covers everything for them is that of the underlying substance of the world around them, and they essay to answer this question, so to speak, by simple inspection. In Socrates and Plato, on the other hand, the start is made from a consideration of man's moral and intellectual activity; but knowledge and action are confused with one another, as in the Socratic doctrine that virtue is knowledge. To this correspond the Platonic confusion of logic and ethics and the attempt to substitute a theory of concepts for a metaphysic of reality. Aristotle's methodic intellect led him to separate the different aspects of reality here confounded. He became the founder of logic, psychology, ethics and aesthetics as separate sciences; while he prefixed to all such (comparatively) special inquiries the investigation of the ultimate nature of existence as such, or of those first principles which are common to, and presupposed in, every narrower field of knowledge. For this investigation Aristotle's most usual name is "first philosophy" or, as a modern might say, "first principles"; but there has since been appropriated to it, apparently by accident, the title "metaphysics." "Philosophy," as a term of general application, was not, indeed restricted by Aristotle or his successors to the disciplines just enumerated. Aristotle himself includes under the title, besides mathematics, all his physical inquiries. And "philosophy" was used in this wide sense (but often divided into "natural" and "moral" or "mental" philosophy) until comparatively recent times, although some of the special sciences had attained to independent cultivation already in the Alexandrian period. However, as the mass of knowledge accumulated, it naturally came about that the name "philosophy" ceased to be applied to inquiries concerned with the particulars as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things. This inquiry which was long called "rational cosmology," may be said to form part of the general subject of metaphysics, or at all events a pendant to it. By the gradual sifting out of the special sciences philosophy thus came to embrace primarily the inquiries grouped as "metaphysics" or "first philosophy." These would embrace, according to the Wolffian scheme long current in philosophical textbooks, ontology proper, or the science of being as such, with its three-branch sciences of (rational) psychology, cosmology and (rational or natural) theology, dealing with the three chief forms of being—the soul, the world and God. Subsidiary to metaphysics, as the central inquiry, stand the sciences of logic and ethics, to which may be added aesthetics, constituting three normative sciences—sciences, that is, which do not, primarily, describe facts, but rather prescribe ends or set forth ideals.

In sum, then, we may say that "philosophy" has come to be understood at least in modern times as a general term covering the various disciplines just enumerated. We shall first of all attempt to differentiate philosophy from the special sciences, and afterwards proceed to take up one by one what have been called the philosophical sciences, with the view of showing how far the usual subject-matter of each is really philosophical in its bearing. The order in which it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge, and ontology, then logic, aesthetics and ethics. Finally, the connection of the last-mentioned with politics (or, to speak more modernly, with jurisprudence and sociology), with the philosophy of history and the philosophy of religion, will call for a few words on the relation of these sciences to general philosophy.

Philosophy and Natural Science.—In distinguishing philosophy from the sciences it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject-matter different from, and in some obscure way transcending, the subject-matter of the sciences. Now that psychology, or the observational and experimental study of mind, may be said to have been definitively included among the positive sciences, there is not even the apparent ground which once existed for such an idea. Philosophy has no other subject-matter than the nature of the real world, as that world lies around us in everyday life, and lies open to observers on every side. But if this is so, it may be asked what function can remain for philosophy when every portion of the field is already lotted out and enclosed by specialists? Philosophy claims to be the science of the whole; but, if we get the knowledge of the part from the different sciences, what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself; it has to show that the subject-matter which we are all dealing with in detail really *is* a whole, consisting of articulated members. Evidently, therefore, the relation existing between philosophy and the sciences will be, to some extent, one of reciprocal influence. The sciences may be said to furnish philosophy with its matter, but philosophical criticism reacts upon the matter thus furnished, and transforms it. Such transformation is inevitable, for the parts only exist and can only be fully, *i.e.*, truly, known in their relation to the whole. A pure specialist, if such a being were possible, would be merely an instrument whose results had to be co-ordinated and used by others. Now, though a pure specialist may be an abstraction of the mind, the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified, and fruitfully applied, in their own sphere of investigation; and in proportion as this is the case it becomes necessary for their theories to be co-ordinated with the results of other inquirers, and set, as it were, in the light of the whole. This task of co-ordination, in the broadest sense, is undertaken by philosophy; for the philosopher is essentially what Plato, in a happy moment, styled him, συνοπτικός, the man who takes a "synoptic" or comprehensive view of the universe as a whole. The aim of philosophy (whether fully attainable or not) is to exhibit the

universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy supplements in this way the abstractions which are inevitably made by the scientific specialist.

For it is evident from what has been said that the way in which we commonly speak of "facts" is calculated to convey a false impression. The world is not a collection of individual facts existing side by side and capable of being known separately. A fact is nothing except in its relations to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this *Unding*, as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, as a theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be *thought out,* or how far, when this is done, they refute themselves, and call for a different form of statement, if they are to be taken as a statement of the ultimate nature of the real. The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe, or, in Spinoza's phrase, *sub specie aeternitatis.* In strictness, there is but one *res completa* or concrete fact, and it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences, including as we shall see, the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of an object for a subject. Subject-object, knowledge, or, more widely, self-consciousness with its implicates—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation, or, in Kantian phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned. On the other hand, a sufficient analysis here may be expected to yield us a statement of the reality of things *in its last terms,* and thus to shed a light backward upon the true nature of our subordinate conceptions.

Psychology, Epistemology and Ontology.—This leads to the consideration of the main divisions of philosophy—psychology (*q.v.*), epistemology (theory of knowledge) and ontology. A special relation has always existed between psychology and systematic philosophy, but the closeness of the connection has been characteristic of modern and more particularly of English thought. The connection is not difficult to explain, seeing that in psychology, or the science of mind, we study the fact of intelligence (and moral action), and have, so far, in our hands the fact to which all other facts are relative. From this point of view we may even see a truth in Jacobi's dictum as quoted by Sir W. Hamilton: "Nature conceals God; man reveals God." Nature by itself, that is to say, is insufficient. The ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge, or the mind's knowing, willing, etc., may be looked at in two different ways. It may be regarded simply as a fact; in which case the evolution of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This study gives us the science of empirical psychology, or, as it is now termed, psychology *sans phrase.* In order to give an adequate account of its subject-matter, psychology may require higher or more complex categories than are employed in the other sciences, just as biology, for example, cannot work with mechanical categories alone, but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy; and the definitive establishment of psychology as an independent science has already been alluded to. Since it has been taken up by specialists, psychology is being established on a broader basis of induction, and with the advantage, in some departments, of the employment of experimental methods of measurement. But it is not of mind in this aspect that such assertions can be made as those quoted above. Mind, as studied by the psychologist—mind as a mere fact or phenomenon—grounds no inference to anything beyond itself. The distinction between mind viewed as a succession of "states of consciousness" and the further aspect of mind which philosophy considers was very clearly put by Croom Robertson, who also made a happy suggestion of two terms to designate the double point of view:

"We may view knowledge as mere subjective function, but it has its full meaning only as it is taken to represent what we may call objective fact, or is such as is named (in different circumstances) real, valid, true. As mere subjective function, which it is to the psychologist, it is best spoken of by an unambiguous name, and for this there seems none better than Intellection. We may then say that psychology is occupied with the natural function of *Intellection,* seeking to discover its laws and distinguishing its various modes (perception, representative imagination, conception, etc.) according to the various circumstances in which the laws are found at work. Philosophy, on the other hand, is theory of *Knowledge* (as that which is known)."—"Psychology and Philosophy," *Mind* (1883), pp. 15, 16.

The confusion of these two points of view has led, and still leads, to serious philosophical misconception. It is hardly an exaggeration to say that, in the English school since Hume, psychology superseded properly philosophical inquiry. And we find even a thinker with a wider horizon like Sir W. Hamilton encouraging the confusion by speaking of "psychology *or* metaphysics," while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper, with an occasional excursus (as in the theory of perception) into epistemology. The distinction between psychology and theory of knowledge was first clearly made by Kant, who repeatedly insisted that the *Critique of Pure Reason* was not to be taken as a psychological inquiry. He defined his problem as the *quid juris* or the question of the validity of knowledge, not its *quid facti* or the laws of the empirical genesis and evolution of intellection (to use Croom Robertson's phraseology). Since Kant, philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not, indeed, a preliminary criticism of our faculties or conceptions such as Kant himself proposed to institute, in order to determine the limits of their application; such a criticism *ab extra* of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent criticism which the conceptions or categories exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explication of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge in the only tenable sense of the term, and it lays down, in Kantian language, the conditions of the possibility of experience. These conditions are the conditions of knowledge as such, or, as it may be put, of objective consciousness—of a self-consciousness of a world of objects and through them conscious of itself. The inquiry is, therefore, transcendental in its nature, and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we inquire into subjective conditions we are

thinking of facts causing other facts. But the transcendental conditions are not causes or even factors of knowledge; they are the statement of its idea. Hence the dispute between evolutionist and transcendentalist rests, in general, on an *ignoratio elenchi;* for the history of the genesis of an idea does not contain an answer to—though it may throw light on—the philosophical question of its truth or validity. Speaking of this transcendental consciousness, Kant goes so far as to say that it is not of the slightest consequence "whether the idea of it be clear or obscure (in empirical consciousness), no, not even whether it really exists or not. But the possibility of the logical form of all knowledge rests on its relation to this apperception as a faculty or potentiality" (*Werke*, ed. Hartenstein, iii. 578 note).

Kant's problem is not, in its wording, very different from that which Locke set before him when he resolved to "inquire into the original, certainty and extent of human knowledge together with the grounds and degrees of belief, opinion and assent." Locke's *Essay* is undoubtedly, in its intention, a contribution to the theory of knowledge. But, because time had not yet made the matter clear, Locke suffered himself to digress in his second book into the psychological question of the origin of our ideas; and his theory of knowledge is ruined by the failure to distinguish between the epistemological sense of "idea" as significant content and the psychological sense in which it is applied to a fact or process in the individual mind. The same confusion runs through Berkeley's arguments and vitiates his conclusions as well as those of Hume. But appearing with these thinkers as the problem of perception, epistemology widens its scope and becomes, in Kant's hands, the question of the possibility of experience in general. With Hegel it passes into a completely articulated "logic," which apparently claims to be at the same time an ontology or an ultimate expression of the nature of the real.

This introduces us to the second part of the question we are seeking to determine, namely the relation of epistemology to ontology. It is evident that philosophy as theory of knowledge must have for its complement philosophy as ontology or theory of being. The question of the truth of our knowledge, and the question of the ultimate nature of what we know, are in reality two sides of the same inquiry; and therefore our epistemological results have to be ontologically expressed. But it is not every thinker that can see his way with Hegel to assert in set terms the identity of thought and being. Hence the theory of knowledge becomes with some a theory of human ignorance. This is the case with Herbert Spencer's doctrine of the Unknowable, which he advances as the result of epistemological considerations in the philosophical prolegomena to his system. Very similar positions were maintained by Kant and Comte; and, under the name of "agnosticism" (*q.v.*), the theory has popularized itself in the outer courts of philosophy, and on the shifting borderland of philosophy and literature. The truth is that the habit of thinking exclusively from the standpoint of the theory of knowledge tends to beget an undue subjectivity of temper. And the fact that it has become usual for men to think from this standpoint is very plainly seen in the almost universal description of philosophy as an analysis of "experience," instead of its more old-fashioned designation as an inquiry into "the nature of things." As it is matter of universal agreement that the problem of being must be attacked indirectly through the problem of knowledge, this substitution may be regarded as an advance, more especially as it implies that the fact of experience, or of self-conscious existence, is the chief fact to be dealt with. But if so, then self-consciousness must be treated as itself real, and as organically related to the rest of existence. If self-consciousness be treated in this objective fashion, then we pass naturally from epistemology to ontology. (For, although the term "ontology" has been as good as disused, it still remains true that the aim of philosophy must be to furnish us with an ontology or a coherent and adequate theory of the nature of reality.) But if, on the other hand, knowledge and reality be *ab initio* opposed to one another—if consciousness be set on one side as over against reality, and merely holding up a mirror to it—then it follows with equal naturalness that the truly real must be something which lurks unrevealed behind the subject's representation of it. Hence come the different varieties of a so-called phenomenalism. The upholders of such a theory would, in general, deride the term "ontology"; but it is evident, none the less, that their position itself implies a certain theory of the universe and of our own place in it, and the establishment of this theory constitutes their ontology.

Without prejudice, then, to the claim of epistemology to constitute the central philosophic discipline, we may simply note its liability to be pressed too far. The exclusive preoccupation of men's minds with the question of knowledge during the neo-Kantian revival in the 'seventies of the last century drew from Lotze the caustic criticism that "the continual sharpening of the knife becomes tiresome, if after all, we have nothing to cut with it." Stillingfleet's complaint against Locke was that he was "one of the gentlemen of this new way of reasoning that have almost discarded substance out of the reasonable part of the world." The same may be said with greater truth of the devotees of the theory of knowledge; they seem to have no need of so old-fashioned a commodity as reality. Yet, after all, Fichte's dictum holds good that knowledge *as* knowledge—*i.e.*, so long as it is looked at as knowledge—is, *ipso facto, not* reality. The result of the foregoing, however, is to show that, as soon as epistemology draws its conclusion, it becomes ontology; the theory of knowledge passes into a theory of being. The ontological conclusion, moreover, is not to be regarded as something added by an external process; it is an immediate implication. The ontology is the epistemology from another point of view—regarded as completing itself, and explaining in the course of its exposition that relative or practical separation of the individual knower from the knowable world, which it is a sheer assumption to take as absolute. This, not the so-called assumption of the implicit unity of being and thought, is the really unwarrantable postulate; for it is an assumption which we are obliged to retract bit by bit, while the other offers the whole doctrine of knowledge as its voucher.

Logic, Aesthetics and Ethics.—If the theory of knowledge thus passes insensibly into ontology it becomes somewhat difficult to assign a distinct sphere to logic (*q.v.*). Ueberweg's definition of it as "the science of the regulative laws of thought" (or "the normative science of thought") comes near enough to the traditional sense to enable us to compare profitably the usual subject-matter of the science with the definition and end of philosophy. The introduction of the term "regulative" or "normative" is intended to differentiate the science from psychology as the science of mental processes or events. In this reference logic does not tell us how our intellections connect themselves as mental phenomena, but how we ought to connect our thoughts if they are to realize truth (either as consistency with what we thought before or as agreement with observed facts). Logic, therefore, agrees with epistemology (and differs from psychology) in treating thought not as mental fact but as knowledge, as idea, as having meaning in relation to an objective world. To this extent it must lead on to the theory of knowledge. But, if we desire to keep by older landmarks and maintain a distinction between the two disciplines, a ground for doing so may be found in the fact that all the main definitions of logic point to the investigation of the laws of thought in a subjective reference—with a view, that is, by an analysis of the operation, to ensure its more correct performance.

Aesthetics (*q.v.*) may be treated as a department of psychology or physiology, and in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism, it is asked, are the emotions due which make us declare an object beautiful or sublime? And, the question being put in this form, the attempt has been made in some cases to explain any peculiarity in the emotions by analysing them into simpler elements, such as primitive organic pleasures and prolonged associations of usefulness or fitness. But, just as psychology in general cannot do duty for a theory of knowledge, so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. Perhaps by talking of "emotions" we tend to give

an unduly subjective colour to the investigation; it would be better to speak of the *perception* of the beautiful. Pleasure in itself is unqualified, and affords no differentia. In the case of a beautiful object the resultant pleasure borrows its specific quality from the presence of determinations essentially objective in their nature, though not reducible to the categories of science. Unless, indeed, we conceive our faculties to be constructed on some arbitrary plan which puts them out of relation to the facts with which they have to deal, we have a *prima facie* right to treat beauty as an objective determination of things. The question of aesthetics would then be formulated—What is it in things that makes them beautiful, and what is the relation of this aspect of the universe to its ultimate nature, as that is expounded in metaphysics? The answer constitutes the substance of aesthetics, considered as a branch of philosophy. But it is not given simply in abstract terms: the philosophical treatment of aesthetics includes also an exposition of the concrete phases of art, as these have appeared in the history of the world, relating themselves to different phases of human culture.

Of ethics (*q.v.*) it may also be said that many of the topics commonly embraced under that title are not strictly philosophical in their nature. They are subjects for a scientific psychology employing the evolutionary method with the conceptions of heredity and development, and calling to its aid, as such a psychology will do, the investigations of all the sociological sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, etc.) and the controversy concerning the freedom of the will belong mainly to psychology. If we exclude such questions in the interest of systematic correctness, and seek to determine for ethics a definite subject-matter, the science may be said to fall into two departments The first of these deals with the notion of duty, and endeavours to define the good or the ultimate end of action; the second lays out the scheme of concrete duties which are deducible from, or which, at least, are covered by, this abstractly stated principle The second of these departments is really the proper subject-matter of ethics considered as a separate science; but it is often conspicuous by its absence from ethical treatises However moralists may differ on first principles, there seems to be remarkably little practical divergence when they come to lay down the particular laws of morality. It may be added that, where a systematic account of duties is actually given, the connection of the particular duties with the universal formula is in general more formal than real. It is only under the head of casuistry (*q.v.*) that ethics has been much cultivated as a separate science. The first department of ethics, on the other hand, is the branch of the subject in virtue of which ethics forms part of philosophy As described above, it ought rather to be called, in Kant's phrase, the metaphysic of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysic of personality. The connection of ethics with metaphysics will be patent as a matter of fact, if it be remembered how Plato's philosophy is summed up in the idea of the good, and how Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connection is also apparent, unless we are to suppose that, as regards the course of universal nature, man is altogether an *imperium in imperio,* or rather (to adopt the forcible phrase of Marcus Aurelius) an abscess or excrescence on the nature of things. If, on the contrary, we must hold that man is essentially related to what the same writer calls "a common nature," then it is a legitimate corollary that in man as intelligence we ought to find the key of the whole fabric.

Philosophy of the State, History and Religion.—In Plato and Aristotle ethics and politics are indissolubly connected. In other words, seeing that the highest human good is realizable only in a community, the theory of the state as the organ of morality, and itself in its structure and institutions the expression of ethical ideas or qualities, becomes an integral part of philosophy. The difficulty already hinted at, which individualistic systems of ethics experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the content of morality we are necessarily referred, in great part, to the experience crystallized in laws and institutions and to the unwritten law of custom, honour and good breeding, which has become organic in the society of which we are members. Plato's *Republic* and Hegel's *Philosophie des Rechts* are the most typical examples of a fully developed philosophy of the state, but in the earlier modern period the prolonged discussion of natural rights and the social contract must be regarded as a contribution to such a theory. Moreover, if philosophy is to complete its constructive work, it must bring the course of human history within its survey, and exhibit the sequence of events as an evolution in which the purposive action of reason is traceable. This is the task of the philosophy of history, a peculiarly modern study, due to the growth of a humanistic and historical point of view. Lessing's conception of history as an "education of the human race" is a typical example of this interpretation of the facts, and was indeed the precursor which stimulated many more elaborate German theories. The philosophy of history differs, it will be observed, from the purely scientific or descriptive studies covered by the general title of sociology. Sociology conceives itself as a natural science elucidating a factual sequence. The philosophy of history is essentially teleological; that is to say, it seeks to interpret the process as the realization of an immanent end. It may be said, therefore, to involve a complete metaphysical theory. Social institutions and customs and the different forms of state-organization are judged according to the degree in which they promote the realization of the human ideal History is thus represented by Hegel, for example, as the realization of the idea of freedom, or rather as the reconciliation of individual freedom and the play of cultured interests with the stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements, we may claim to possess a philosophy of history But although the possibility of such a philosophy seems implied in the postulated rationality of the universe many would hold that it remains as yet an unachieved ideal.

There only remains to be briefly noticed the relation of philosophy to theology and the nature of what is called Philosophy of Religion By theology is commonly understood the systematic presentation of the teaching of some positive or historical religion as to the existence and attributes of a Supreme Being, including his relation to the world and especially to man But these topics have also been treated by philosophers and religious thinkers, without dependence on any historical data or special divine revelation, under the title of Natural Theology. Natural Theology is specially associated with the Stoic theories of providence in ancient times and with elaborations of the argument from design in the 18th century. But there is no warrant for restricting the term to any special mode of approaching the problems indicated; and as these form the central subject of metaphysical inquiry, no valid distinction can be drawn between natural theology and general metaphysics The philosophy of religion, on the other hand, investigates the nature of the religious consciousness and the value of its pronouncements on human life and man's relation to the ground of things. Unity, reconciliation, peace, joy, "the victory that overcometh the world"—such, in slightly varying phrases, is the content of religious faith. Does this consciousness represent an authentic insight into ultimate fact, or is it a pitiful illusion of the nerves, born of man's hopes and fears and of his fundamental ignorance? The philosophy of religion assumes the first alternative. The function of philosophy in general is the reflective analysis of experience, and the religious experience of mankind is *prima facie* entitled to the same consideration as any other form of conscious activity. The certainties of religious faith are matters of feeling or immediate assurance, and are expressed in the pictorial language of imagination. It becomes the function of philosophy, dealing with these utterances, to relate them to the results of other spheres of experience, and to determine their real meaning in the more exact terms of thought.

The philosophy of religion also traces in the different historical forms of religious belief and practice the gradual evolution of what it takes to be the truth of the matter. Such an account may be distinguished from what is usually called the science of religion by the teleological or metaphysical presuppositions it involves. The science of religion gives a purely historical and comparative account of the various manifestations of the religious instinct without pronouncing on their relative truth or value and without, therefore, professing to apply the idea of evolution in the philosophical sense. That idea is fundamental in the philosophy of religion, which therefore can be written only from the standpoint of a constructive metaphysical theory.

It is, indeed, only from the standpoint of such a theory that the definitions and divisions of the different philosophical disciplines adopted in this article can be said to hold good. But those who, like the positivist, agnostics and sceptics, deny the possibility of ontology as a theory of the ultimate nature of things, are still obliged to retain philosophy as a theory of knowledge, in order to justify the asserted limitation or impotence of human reason.

PHILOSTRATUS, "THE ATHENIAN" (*c.* 170–245), the author of the *Life of Apollonius of Tyana*, which he dedicated to Julia Domna, wife of Alexander Severus and mother of Caracalla (*see* Apollonius of Tyana). He wrote also Βίοι Σοφιστῶν (*Lives of the Sophists*), *Gymnasticus* and *Epistolae* (mainly of an erotic character). Very little is known of his career. It is probable that he was born in Lemnos, studied and taught at Athens, and then settled in Rome. He is said by Suidas to have been living in the reign of Philip (224–249). The common authorship of *Apollonius* and of the *Lives of the Sophists* is confirmed by internal evidence.

The *Lives* are not in the true sense biographical, but rather picturesque impressions of leading representatives. The *Gymnasticus* contains interesting matter concerning the Olympic games and contests. The *Letters* breathe the spirit of the New Comedy and the Alexandrine poets; portions of *Letter 33* are almost literally translated in Ben Jonson's *Song to Celia*, "Drink to me only with thine eyes." The Ἡρωικός, formerly attributed to Philostratus the Athenian, but probably by another Philostratus ("of Lemnos"), is a popular disquisition on the heroes of the Trojan War. His other work is the Εἰκόνες (*Imagines*), ostensibly a critical description of 64 pictures in a Neapolitan gallery.

See K. Münscher in *Philologus* (1907) suppl. X., pp. 469–557. Of works bearing the name Philostratus there is a collected edition by C. F. Kayser (Zurich, 1844; Leipzig, 1870–71), and another by Westermann (Paris, 1849), with Latin translation; these supersede those by F. Morel (Paris, 1608) and Olearius (Leipzig, 1709). There are separate editions of the *Eikones* by Schenkl and Reisch (Leipzig, 1902); of the *Gymnasticus* by Mynas (1858), Daremberg (1858), Volckmar (Zurich, 1862), and especially Julius Jüthner (1909), with introd., comments and Ger. trans.; of 73 epistles by Boissonade (1842). The *Life of Apollonius* was first published by Aldus (1502); a French translation by Blaise de Vigenère appeared in 1596; an Eng. trans. of bks. i. and ii. was published (1680) by C. Blount, with notes by Lord Herbert of Cherbury (prohibited in England in 1693, it was reprinted on the Continent); a full translation appeared in 1903. Critical works on the *Eikones* are numerous: K. Friederichs, *Die Philostratischen Bilder* (1860); Goethe, "Philostrats Gemälde" in *Complete Works* (ed. Stuttgart, 1879); Brunn, *Die Philostratischen Bilder* (1860); A. Bougot, *Une Galérie antique* (1881); E. Bertrand, *Un Critique d'art dans l'antiquité: Philostrate et son école* (1882); Bergk, "Die Philostrate" in *Fünf Abhandlungen zur Geschichte der griechischen Philosophie und Astronomie* (1883); Schmid, *Atticismus* iv. 7, on the attribution of the works, and Überweg, *Grundriss der Gesch. der Philosophie*, Bd. I. (1926).

PHILOXENUS, of Cythera (435–380 B.C.), Greek dithyrambic poet. On the conquest of the island by the Athenians he was taken as a prisoner of war to Athens, where he was purchased by the dithyrambic poet Melanippides, who educated him and set him free. Philoxenus afterwards resided in Sicily, at the court of Dionysius, tyrant of Syracuse, whose bad verses he declined to praise, and was in consequence sent to work in the quarries. After leaving Sicily he travelled in Greece, Italy and Asia, reciting his poems, and died at Ephesus. According to Suidas, Philoxenus composed twenty-four dithyrambs and a lyric poem on the genealogy of the Aeacidae. In his hands the dithyramb seems to have been a sort of comic opera, and the music, composed by himself, of a debased character. His masterpiece was the *Cyclops*, a pastoral burlesque on the love of the Cyclops for the fair Galatea, written to avenge himself upon Dionysius, who was wholly or partially blind of one eye. It was parodied by Aristophanes in the *Plutus* (290). The popularity of Philoxenus is attested by a complimentary resolution passed by the Athenian senate in 393.

Fragments, with life, by G. Bippart (1843); T. Bergk, *Poetae lyrici graeci*.

PHILOXENUS (Syriac, Aksēnāyā) (*fl. c.* 500) of Mabbōg, one of the best of Syriac prose writers, and a vehement champion of Monophysite doctrine. He was by birth a Persian, born at Taḥal, in the district of Bēth Garmai east of the Tigris. He was educated at Edessa. Philoxenus soon attracted notice by his strenuous advocacy of Monophysite doctrine, and on the expulsion of Calandio (the orthodox patriarch of Antioch) in 485 was ordained bishop of Mabbōg (Hierapolis) by his Monophysite successor Peter the Fuller (Barhebraeus, *Chron. eccl.* i. 183). It was probably during the earlier years of his episcopate that Philoxenus composed his thirteen homilies on the Christian life. Later he revised the Syriac version of the Bible, and with the help of his chorepiscopus Polycarp produced in 508 the so-called Philoxenian version, used by the Monophysites during the 6th century. He bitterly opposed Flavian II., who had accepted the decrees of the Council of Chalcedon and was patriarch of Antioch from 498 to 512. In 512 the Monophysites finally ousted and replaced him by their partisan Severus. But Justin I., who succeeded Anastasius in 518, was less favourable to Severus and Philoxenus, and in 519 they were sentenced to banishment. Philoxenus was sent to Philippopolis in Thrace, and afterwards to Gangra in Paphlagonia, where he met his death by foul play in 523.

Of the chief monument of his scholarship—the Philoxenian version of the Bible—only the Gospels and certain portions of Isaiah are known to survive (*see* Wright, *Syr. Lit.* 14). His thirteen homilies on the Christian life and character have been edited and translated by Budge (London, 1894). Many of his letters survive.

PHIPS or **PHIPPS, SIR WILLIAM** (1651–1695), colonial governor of Massachusetts, was born on Feb. 2, 1651, at Woolwich, Me., near the mouth of the Kennebec river. He was a shepherd until he was 18 and then a ship carpenter's apprentice for four years; worked at his trade in Boston for a year, at this time learning to read and write. In 1687, with a commission from the British Crown, he found, after a search of many years, a wrecked Spanish treasure ship of which he had heard on a voyage to the Bahamas. From it he recovered £300,000, of which he received £16,000 as his share, was knighted by James II., and was appointed sheriff of New England. Poorly educated and ignorant of law, Phips could accomplish little, and returned to England. In 1689 he returned to Massachusetts, and at once entered into the life of the colony. He was soon appointed commander of an expedition against the French in Canada, which sailed in April, 1690, and easily captured Port Royal. A much larger expedition led by Phips in July against Quebec and Montreal ended disastrously. In the winter of 1690 he returned to England, and urged, with Increase Mather, the colonial agent, a restoration of the colony's charter, annulled during the reign of Charles II. The Crown, at the suggestion of Mather, appointed him the first royal governor under the new charter. On reaching Boston in May, 1692, Phips found the colony in a very disordered condition, and though honest and persevering, he was unfitted for the difficult position. In defending the frontier he displayed great energy, but his policy of building forts was expensive and therefore unpopular. Numerous complaints to the home government resulted in his being summoned to England to answer charges. While in London awaiting trial, he died on Feb. 18, 1695.

See Cotton Mather's *Life of His Excellency Sir William Phips*

(1697; republished in his *Magnalia* in 1702); Francis Bowen's "Life of Sir William Phips," in Jared Sparks's *American Biography*, 1st series, vol. vii. (1856); William Goold's "Sir William Phips," in *Collections of the Maine Historical Society*, series 1, vol. ix. (Portland, 1887); Ernest Myrand's *Sir William Phipps devant Quebec* (Quebec, 1893); Thomas Hutchinson's *History of Massachusetts* (Boston; 3rd ed. 1795); and J. G. Palfrey's *History of New England* (1858–90).

PHLEBITIS, a medical term for inflammation affecting veins. Usually the venous condition results from inflammation in tissue surrounding the vessel and extending to its walls. The vein becomes thickened and can be recognized as a definite, perhaps reddened, and very painful cord if it be superficial, *e.g.*, saphenous vein. When the inflammation extends to the inner coat of the vessel and nutrition of the lining endothelium is impaired, local clotting of blood occurs, the clot being adherent to the vessel wall where it is first formed and extending upwards and downwards within the lumen (*see* THROMBOSIS AND EMBOLISM). From the primary focus clotting extends also into the tributaries of the vein thus inducing widespread obstruction to the return of blood from the part and consequent oedema. The condition calls for complete rest owing to the danger of dislocating the clot and causing embolism; this danger is greatest when the condition is septic. In most cases, under rest, the inflammation subsides and the primarily affected vein becomes permanently occluded by newly formed fibrous tissue, but circulation in the part formerly drained by the vein is restored by the opening up of collateral channels. In some regions phlebitis is particularly dangerous, *e.g.*, the lateral sinus to which inflammation from middle ear disease may extend with subsequent cerebral abscess or purulent meningitis or general pyaemia. In such cases surgery is the sole hope for the patient.

PHLEGON, of Tralles in Asia Minor, Greek writer and freedman of the emperor Hadrian, flourished in the 2nd century A.D. His chief work was the *Olympiads*, an historical compendium in sixteen books, from the 1st down to the 229th Olympiad (776 B.C. to A.D. 137), of which several chapters are preserved in Photius and Syncellus. Two small works by him are extant: *On Marvels* and *On Long-lived Persons,* a list of Italians who had passed the age of 100, taken from the Roman censuses.

Fragments in C. Müller, *Frag. hist. graec.* iii.; of the *Marvels* and *Long-lived* in O. Keller, *Rerum naturalium scriptores*, i. (1877); *see* also H. Diels, "Phlegons Androgynenorakel" in *Sibyllinische Blätter* (1890).

PHLOGOPITE, a mineral belonging to the group of micas (*q.v.*). It is a magnesium mica, differing from biotite in containing only a little iron; $[H,K,(MgF)]_3Mg_3Al(SiO_4)_3$, is the chemical formula and it is named from Gr. φλογωπός (fiery-looking), the mineral being sometimes brownish-red and coppery in appearance. Sometimes it is quite colourless and transparent, but usually of a characteristic yellowish-brown colour, and often with a silvery lustre on the cleavage surfaces, hence the trade names "amber mica" and "silver mica" for some varieties. Phlogopite occurs chiefly as scales and plates embedded in crystalline limestones of the Archaean formation, and the cleavage flakes are not quite so elastic as those of muscovite. The mica mined in Canada and Ceylon is mainly phlogopite, and is largely used as an insulator for electrical purposes. In Canada it occurs with apatite in pyroxene rocks associated with Laurentian gneisses and crystalline limestones, the principal mining district being in Hull county, Quebec and near Burgess in Lanark county, Ontario. In Ceylon the mineral forms irregular veins, rarely exceeding one or two feet in width, traversing granulite, especially near the contact of this rock with crystalline limestone.

PHLOX (family Polemoniaceae), a genus of about 60 species, mostly perennial hardy plants of great beauty, natives of North America (one occurs in Siberia), with entire, usually opposite, leaves and showy flowers generally in terminal clusters. Each flower has a tubular calyx with five lobes, and a salver shaped corolla with a long slender tube and a flat limb. The five stamens are given off from the tube of the corolla at different heights and do not protrude beyond it. The ovary is three-celled with one to two ovules in each cell; it ripens into a three-valved capsule. Many species and varieties are tall herbs yielding a wealth of bloom throughout the summer and early autumn. They require a deep, rich and rather heavy loam, and a cool, moist position.

The dwarf perennial species and varieties, the "moss pinks" of gardens, are suitable plants for the rockery, and as edging to beds and borders. They are trailing and tufted in habit, the branches rooting at the nodes. They succeed in poorer soil, and drier situations than the tall kinds. Seed is seldom produced. Propagation is effected by cuttings in July and early August, placed in a cold frame, and by division of the plants, which should be lifted carefully, and cut into rooted portions as required. The tufted kinds decay in patches in winter if the situation is moist.

Phlox Drummondii and its numerous varieties are half-hardy annuals in Great Britain. It is a small-growing hairy plant, flowering profusely during the summer months. For early flowering it should be sown in heat in March and April and transferred out of doors in June. It succeeds if sown out of doors in April, but the flowering season is later and shorter.

The tall-growing border phloxes are divided into early and late flowering kinds respectively, the former derived mainly from *P. glaberrima* and *P. suffruticosa*, and the latter from *P. maculata* and *P. paniculata*. Owing to the frequent introduction of new kinds, no account of varieties can be given.

As practically all the species are native to the United States, with handsome representatives in every section of the country, admirers of this beautiful genus of plants have urged its adoption as the floral emblem or national flower of America.

PHOCAEA (mod. *Fokia* or *Fokha*), an ancient city on the western coast of Asia Minor, famous as the mother city of Marseilles. It was the most northern of the Ionian cities, and was situated on the coast of the peninsula which separates the gulf of Cyme, occupied by Aeolian settlers, from the Hermaean Gulf, on which stood Smyrna and Clazomenae. Its position between two good harbours, Naustathmus and Lampter (Livy xxxvii. 31), led the inhabitants to devote themselves to maritime pursuits. According to Herodotus the Phocaeans were the first of all the Greeks to undertake distant voyages, and made known the coasts of the Adriatic, Tyrrhenia and Spain. Arganthonius, king of Tartessus in Spain, invited them to emigrate in a body to his dominions, and, on their declining, presented them with a large sum of money. This they employed in constructing a strong wall around their city, a defence which stood them in good stead when Ionia was attacked by Cyrus in 546. Eventually they determined to seek a new home in the west, where they already had flourishing colonies, *e.g.*, Alalia in Corsica and Massilia (mod. *Marseilles*). A large part of the emigrants proceeded only as far as Chios, returned to Phocaea, and submitted to the Persian yoke.

Phocaea continued to exist under the Persian government, but greatly reduced in population and commerce. Though it joined in the Ionian revolt against Persia in 500 it was able to send only three ships to the combined fleet which fought at Lade. But a Phocaean took the supreme command. It never again played a prominent part in Ionian history. The modern town in the immediate neighbourhood, still known as Fokia, was founded by the Genoese in 1421 on account of the rich alum mines in the neighbourhood. It has a fair natural harbour.

PHOCAS, East Roman emperor (602–610), was a Cappadocian of humble origin. He was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterwards resulted in the abdication of the reigning emperor Maurice, and in the elevation of Phocas to the throne. Phocas proved entirely incapable of governing the empire. He consented to pay an increased tribute to the Avars and allowed the Persians to overrun the Asiatic provinces and to penetrate to the Bosporus. When the African governor Heraclius declared against him, Phocas was deposed with scarcely a struggle (610). He died in the same year on the scaffold.

See J. B. Bury, *The Later Roman Empire* (1923), vol. ii.; Gibbon, *Decline and Fall* (ed. Bury, 1911), vol. 5, p. 65–7050; J. Kulakowsky in "Byzant. Vremmenik" vol. xxi.

PHOCION, Athenian statesman and general, was born about 402 B.C., the son of a small manufacturer. He became a pupil of Plato and in later life was a close friend of Xenocrates. Under

Chabrias he distinguished himself in the great sea-fight of Naxos (376), and subsequently won the confidence of the allies by his justice and integrity. In 351–349 he entered the Persian service and helped to subdue a rebellion in Cyprus. Henceforward he always held a prominent position in Athens, and although he never canvassed he was elected general forty-five times in all. In politics he is known chiefly as the consistent opponent of the anti-Macedonian party. He countered the eloquence of Demosthenes and his supporters by the plain facts of Athens' situation. He helped to defend Aeschines in 343, and secured lenient terms from Philip after the disaster of Chaeroneia (338). He also rendered good service in the field: in 348 he saved the force operating against the philo-Macedonian tyrants in Euboea by the brilliant victory of Tamynae. Under the Macedonian predominance his reputation increased. Though by no means inclined to truckle to the Macedonians, as is shown by his protection of the refugee Harpalus and his spirited campaign in defence of Attica in 322, he won the confidence of the conquerors, and in the restricted democracy which Antipater enforced he became the virtual ruler of Athens. On the restoration of the democracy in 318, Phocion was deposed. He fled to Polyperchon, but was sent back to be tried at Athens. The assembly shouted Phocion down and condemned him to death unheard. Not long after, the Athenians decreed a public burial and a statue in his honour.

See Plutarch, *Life of Phocion;* Holm. *Gk. Hist.* vol. iii. (Eng. trans., London, 1896).

PHOCIS, an ancient district of central Greece (now a department, pop. *c.* 65,000, area, 625 sq.m.), bounded on the W. by Ozolian Locris and Doris, on the N. by Opuntian Locris, on the E. by Boeotia, and on the S. by the Corinthian Gulf. The massive ridge of Parnassus (8,068 ft.), traverses the heart of the country. Between this and the northern frontier range of Cnemis (3,000 ft.) is the narrow fertile valley of the Cephissus, along which lie most of the Phocian townships. South of Parnassus the two small plains of Crisa and Anticyra are separated by Mt. Cirphis. Phocis was mainly pastoral.

Its early history is obscure. Its population was reckoned Aeolic, but the dialects are of the West-Greek group, more akin to Doric. There was a tradition that the Phocians once owned land round Daphnus opposite Euboea, and had their frontier at Thermopylae. Later restriction of territory was due to the hostility of Boeotia and Thessaly. The latter in the 6th century even raided the Cephissus valley. In early days Phocians controlled the sanctuary of Delphi. But Delphi constantly strove for independence and about 590 B.C. induced a coalition of Greek states to proclaim a "Sacred War" and free the oracle from Phocian supervision. Thus Phocian influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence, but their irresolute conduct lost Thermopylae for the Greeks; and at Plataea they were on the Persian side. In 457 an attempt to control the head waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the "metropolis of the Dorians." A similar attack on Delphi in 448 was again frustrated by Sparta, but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians, with whom they became allied in 454. When Athenian land-power declined, Phocian friendship waned, and in the Peloponnesian War Phocis was nominally an ally of Sparta, and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by Boeotian oppression. After helping Sparta to invade Boeotia during the Corinthian War (395–394), the Phocians received assistance from Sparta in 380, but afterwards submitted to the growing power of Thebes. Phocians took part in Epameinondas' earlier inroads into the Peloponnesus, but abstained from the campaign of Mantineia (370–362). In return for this negligence the Thebans secured a penal decree against them for religious offences from the Amphictyonic synod (356). The Phocians, led by two capable generals, Philomelus and Onomarchus, replied by seizing Delphi and using its riches to hire mercenaries with whose help they invaded Boeotia and Thessaly, and though driven out of Thessaly by Philip of Macedon, maintained themselves for ten years, until the exhaustion of the temple treasures and the treachery of their leaders placed them at Philip's mercy. In 339 the Phocians began to rebuild their cities; in 338 they fought against Philip at Chaeroneia; in 323 they took part in the Lamian War against Antipater, and in 279 helped to defend Thermopylae against the Gauls.

During the 3rd century Phocis passed into the power of Macedonia and of the Aetolian League, to which in 196 it was annexed. Under Roman rule its league was dissolved, but was revived by Augustus, who also restored to Phocis the votes in the Delphic Amphictyony which it had lost in 346 and enrolled it in the new Achaean synod. The Phocian League is last heard of under Trajan.

PHOCYLIDES, Greek gnomic poet of Miletus, contemporary of Theognis, was born about 560 B.C. A few fragments of his "maxims" have been preserved (chiefly in the *Florilegium* of Stobaeus). A complete didactic poem called Ποίημα νουθετικόν or γνῶμαι, and which bears the name of Phocylides, is now considered to be the work of an Alexandrian Christian of Jewish origin who lived between 170 B.C. and A.D. 50.

See fragments and the spurious poem in T. Bergk, *Poetae lyrici graeci,* ii. (4th ed., 1882); J. Bernays *Über das Phokylideische Gedicht* (1858); *Phocylides, Poem of Admonition,* with introduction and commentaries by J. B. Fenling, and translation by H. D. Goodwin (Andover, Mass., 1879). There is an English verse translation by W. Hewett (Watford, 1840), *The Perceptive Poem of Phocylides.*

PHOEBE (*Sayornis phoebe*), the name given to a familiar American bird belonging to the family *Tyrannidae* (the "American flycatchers"). Distinguished by its dark crown-cap, olive-grey plumage, and the white outer vane to the outer tail feather, the phoebe breeds in eastern North America from the south-west Mackenzie southwards, wintering in southern U.S.A. and Mexico. The bulky nest of moss and mud, lined with grass, hair and feathers, is placed on a beam or under a bridge or bank, often close to or on a building. Say's phoebe (*S. sayi*) is a more westerly species, abundant west of Kansas and Nebraska. The black phoebe (*S. nigricans*) has a more southern range.

PHOEBUS, a common epithet of Apollo (*q.v.*).

PHOENICIA, in ancient geography, the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el-Kebir) in the north to Mt. Carmel in the south, a distance of rather more than two degrees of latitude. These limits, however, were exceeded at various times; thus, north of the Eleutherus lay Aradus and Marathus, and south of Carmel the border sometimes included Dor and even Joppa. The harbours which played so important a part in antiquity are nearly all silted up, and, with the exception of Beirut, afford no safe anchorage for the large vessels of modern times. Sidon, Tyre and Aradus, though now connected with the mainland, were built originally upon islands; the Phoenicians preferred such sites, because they were convenient for shipping and easily defended against attack.

The chief towns of ancient Phoenicia, as we know of them from the Amarna tablets (15th century B.C.) and from Egyptian, Assyrian and the Old Testament documents, were the following: Acco (now Acre or 'Akkā, Judg. i. 31), Achzib (now ez-Zīb, *ibid.*), Ahlab (in Assyrian Mahalliba, *ibid.*)—three towns on the coast south of Tyre, Kānāh (Josh. xix. 28), Tyre (Phoen. Sōr, now Sūr), Zarephath or Sarepta (1 Kings xvii. 9 [now Sarafand]), Sidon (now Ṣaidā), Berytus (Biruta in Egyptian, Biruna in the Amarna tablets, now Beirūt), Byblus (in Phoen. and Hebr. Gebal, now Jebeil), Arka, 80m. north of Sidon (Gen. x. 17, now 'Arḳā), Sin (Assyr. Siannu, *ibid.*) Simyra (Gen. x. 18, now Ṣumrā), Marathus (now Amrīt) not important till the Macedonian period, Arvad or Aradus (in Phoen. Arwād, now Ruād, Gen. x. 18; Ezek. xxvii. 8, 11), the most northerly of the great Phoenician towns.

Race and Language.—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. The Phoenicians themselves believed that they had migrated from an eastern shore, probably meaning Babylonia.

By settling along the Syrian coast they developed a strangely un-Semitic love for the sea, and advanced on different lines from the other Canaanites who occupied the interior. They called themselves Canaanites and their land Canaan; such is their name in the Amarna tablets, *Kinahhi* and *Kinahni;* and with this agrees the statement assigned to Hecataeus (*Fr. hist. gr.*, i. 17) that Phoenicia was formerly called Χνᾶ (*Chnâ*) a name which Philo of Byblus adopts into his mythology by making "Chna who was afterwards called Phoinix" the eponym of the Phoenicians (*Fr. hist. gr.*, iii. 569). In the reign of Antiochus IV. and his successors the coins of Laodicea of Libanus bear the legend "Of Laodicea which is in Canaan" (Cooke, *North-Semitic Inscriptions,* quoted as *NSI.*, No. 149 B 8); the Old Testament also sometimes denotes Phoenicia and Phoenicians by "Canaan" and "Canaanites" (Isa. xxiii. 11; Obad. 20; Zeph. i. 11), though the latter names generally have a more extended sense. But "Sidonians" is the usual designation both in the Old Testament and in the Assyrian monuments (Sidunnu); and even at the time of Tyre's greatest ascendancy we read of Sidonians and not Tyrians in the Old Testament and in Homer; thus Ethbaal, king of Tyre (Jos., *Ant.*, viii. 13, 2) is called king of the Sidonians in 1 Kings xvi. 31. In the Homeric poems we meet with *Sidonioi, Sidoniē* (Od., iv. 618; *Il.*, vi. 290; *Od.*, xiii. 285; *Il.*, vi. 291) and *Phoinikes, Phoinikē* (*Od.*, xiii. 272, xiv. 288 *seq.*, etc.), and both terms together (*Od.*, iv. 83 *seq.*, *Il.*, xxiii. 743 *seq.*). And the Phoenicians themselves used Sidonians as a general name; thus in one of the oldest Phoenician inscriptions (*CIS.*, i. 5=*NSI.*, No. 11), Hiram II., king of Tyre in the 8th century, is styled "king of the Sidonians." But among the Greeks "Phoenicians" was the name most in use, *Phoinikes* (plur. of *Phoinix*) for the people and *Phoinikē* for the land (*cf.* PHOENIX). The former was probably the older word and may be traced to *phoinos*="blood-red"; the Canaanite sailors were spoken of as the "red men" on account of their sunburnt skin.

Language.—Inscriptions, coins, topographical names preserved by Greek and Latin writers, names of persons and the Punic passages in the *Poenulus* of Plautus, all show conclusively that the Phoenician language belonged to the North-Semitic group, and to that sub-division of it which is called the Canaanite and includes Hebrew and the dialect of Moab. A comparison between Phoenician and Hebrew reveals close resemblances both in grammatical forms and in vocabulary; in some respects older features have been preserved in Phoenician, others are later, others again are peculiar to the dialect; many words poetic or rare or late in Hebrew are common in Phoenician. Hence we may conclude that the two languages developed independently from a common ancestor, which can be no other than the ancient Canaanite, of which a few words have survived in the Canaanite glosses to the Amarna tablets (written in Babylonian). But in forming an estimate of the Phoenician language it must be remembered that our material is scanty and limited in range; the Phoenicians were in no sense a literary people; moreover, except the inscriptions found at Gebal, now Jebeil, (10th century) and *NSI.* No. 11, most of the inscriptions are subsequent to the 6th century B.C.; the majority belong to the 4th century and later, by which time the language must have undergone a certain amount of decay. Indirectly, however, the Phoenicians rendered one great service to literature; they took a large share in the development and diffusion of the alphabet which forms the foundation of Greek (Herod., v. 58) and of all European writing. The Phoenician letters in their earlier types are practically identical with those used by the Hebrews, the Moabites, and the Aramaeans of north Syria (*NSI.*, Plates xii., xiii). They passed through various modifications in the course of time; after leaving the mother country the script acquires a more cursive flowing style on the stones from Cyprus and Attica; the tendency becomes more strongly marked at the Punic stage; until in the neo-Punic, from the destruction of Carthage (146 B.C.) to the 1st century A.D., both the writing and the language reached their most degenerate form. As a rustic dialect the language lasted in north Africa till the 5th century A.D. In his sermons St. Augustine frequently quotes Punic words. The oldest specimens of Phoenician writing at present known have been found at Gebal. In 1922 Montet unearthed the sarcophagus of Aḥîram, incised with a Phoenician inscription in an archaic form of lettering, which bears a close resemblance to the inscription of Abi-baal, discovered some years ago on the same site.

History.—The Phoenicians, in imitation of the Egyptians, claimed that their oldest cities had been founded in remote antiquity; but no certainty can be attached to the traditional chronologies; *e.g.*, Herod., ii. 44; Justin, xviii. 3; Menander in Jos., *Ant.*, viii. 3, 1 and *c. Ap.*, i. 18.

Phoenicia comes into history proper *c.* 1600 B.C., when the Egyptian empire began to extend in the direction of Asia under Aḥmosi (Amasis) I.; who carried his arms into Syria, and conquered at least Palestine and Phoenicia, the latter being the country called *Da-hi* on the Egyptian monuments (Müller, *As. u. Eur.*, p. 181). Thothmes III. (1503–1449) repeated and consolidated the earlier conquest, and established Egyptian suzerainty over all the petty states of Syria and Phoenicia (*see* EGYPT: *History.* I.). For the geography and civilization of Canaan about 1400 B.C. we have valuable evidence in the Egyptian papyrus Anastasi I., which mentions Kepuna (Gubna, Gebal-Byblus) the holy city, and continues: "Come then to Berytus, to Sidon, to Sarepta. Where is the ford of Nat-'ana (? Nahr el-Ḳāsimīyeh, or a town)? Where is 'Eutu (?Ushu, Palaetyrus)? Another city on the sea is called a haven, D'ar (Tyre) is its name, water is carried to it in boats; it is richer in fish than in sands." But the fullest information about the state of Phoenicia in the 15th and 14th centuries B.C. comes from the Amarna tablets, among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh. It was a time of much political disturbance. The Hittites (*q.v.*) were invading Syria; nomads from the desert supported the invasion; and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were divided; Aradus, Simyra, Sidon supported the rebellion; Rib-addi, the regent of Byblus, and Abi-melech, king of Tyre, held out for Egypt; but while all the towns made professions of fidelity, they were scheming for their own interests, and in the end Egypt lost them all except Byblus. The tablets which reveal this state of affairs are written in the language and script of Babylonia, and thus show indirectly the extent to which Babylonian culture had penetrated Palestine and Phoenicia; at the same time they illustrate the closeness of the relations between the Canaanite towns and the dominant power of Egypt. After the reign of Amenophis IV. (1376–66) that power collapsed altogether; but his successors attempted to recover it, and Ramses (Rameses) II. reconquered Phoenicia as far as Beirut, and carved three tablets on the rock beside the Nahr el-Kelb (Gressmann, *Texte u. Bilder*^{2} ii. Pl. lxv.). In the reign of Ramses III. (*c.* 1200) many great changes began to occur owing to the invasion of Syria by peoples from Asia Minor and Europe, which ended in the establishment of the Philistines on the coast near Ashkelon. The successors of Ramses III. lost their hold over Canaan; the 21st dynasty no longer intervened in the affairs of Syria; but Sheshonk (Shishak), the founder of the 22nd dynasty, about 928 B.C. endeavoured to assert the ancient supremacy of Egypt (*cf.* 1 Kings xiv. 25 *sqq.*), but his successes were not lasting, and, as we learn from the Old Testament, the power of Egypt became henceforward ineffective.

Independence of Phoenicia.—Between the withdrawal of the Egyptian rule in Syria and the western advance of Assyria there comes an interval during which the city-states of Phoenicia owned no suzerain. Gebal had kings of its own, Aḥîram, Ithobaal, Abi-baal, in the 10th century, as recent excavations have shown. The history of this period is mainly a history of Tyre, which not only rose to a sort of hegemony among the Phoenician states, but founded colonies beyond the seas (p. 769). From 970 to 772 B.C. the bare outline of events is supplied by extracts from two Hellenistic historians, Menander of Ephesus and Dius (largely dependent upon Menander), which have been preserved by Josephus, *Ant.*, viii. 5, 3 and *c. Ap.*, i. 17, 18. From the data given in these passages we learn that Hiram I., son of Abi-baal, reigned in Tyre from 970 to 936 B.C. The Tyrian annals, more-

over, alluded to the connection between Hiram and Solomon. Before this time, indeed, the Phoenicians had no doubt lived on friendly terms with the Israelites (*cf.* Judges v. 17; Gen. xlix. 13); but the two nations seem to have drawn closer in the time of Solomon. 2 Sam. v. 11, which brings David and Hiram together, probably antedates what happened in the following reign. For Solomon's palace and temple Hiram contributed cedar and fir trees as well as workmen, receiving in exchange large annual payments of oil and wine, supplies which Phoenicia must have drawn regularly from Israelite districts (1 Kings v. 9, 11; *cf.* Ezek., xxvii. 17; Ezr. iii. 7; Acts xii. 20; Jos., *Ant.* xiv. 10, 6); finally, in return for the gold which he furnished for the temple, Hiram received the grant of a territory in Galilee (Cabul, 1 Kings ix. 10–14). This alliance between the two monarchs led to a joint expedition from Eziongeber on the Gulf of Akaba to Ophir (?on the east coast of Arabia, *see* Ophir) for purposes of trade. The list of Hiram's successors given by Josephus indicates frequent changes of dynasty until the time of Ithobal I., priest of Astarte, whose reign (887–855) marks a return to more settled rule. In contrast to Hiram I., king of Tyre, Ithobal or Ethbaal is styled in 1 Kings xvi. 31 "king of the Sidonians," *i.e.*, of the Phoenicians, showing that in the interval the kings of Tyre had extended their rule over the other Phoenician cities. Under Ethbaal further expansion is recorded; Botrys north of Byblus and Aoza in north Africa are said to have been founded by him (Jos., *Ant.*, viii. 13, 2); the more famous Carthage owed its origin to the civil discords which followed the death of Metten I. (*c.* 851), his next successor but one. According to tradition, Metten's son Pygmalion (*c.*860–814) slew the husband of his sister Elissa or Dido; whereupon she fled and founded Carthage (*q.v.*) in Libya (Justin, xviii. 4–6). At this point Josephus's extracts from Menander end, *see* Schrader, *KAT.*, 3rd ed. 12G ff.).

Assyrian Rule, 876–605 B.C.—From the time of Ethbaal onwards the independence of Phoenicia was threatened by the advance of Assyria. In 868 B.C. Assur-nasir-pal III. "washed his weapons in the great sea," and exacted tribute from the kings of Tyre, Sidon, Byblus and other cities, including Arvad (*Keilinschr. Bibliothek*, i. 109). The inscriptions of his son Shalmaneser II. mention the taking of tribute from the Tyrians and Sidonians in 842 and again in 839; the Byblians are included at the latter date, and among the kings defeated at Karkar in 854 or 853 was Metten-baal, king of the Arvadites (*ibid.*, pp. 141, 143, 173). Thus Shalmaneser established a supremacy which lasted for over a hundred years and was acknowledged by occasional payments of tribute. In 741 Tiglath-pileser III. mentions on his tribute-lists "Ḥirûm of Tyre"; and here a piece of native evidence becomes available. An early Phoenician inscription (*CIS.* i. 5= *NSI.* No. 11), engraved upon the fragments of a bronze bowl, mentions a certain governor of Qarth-ḥadasht (or Karti-Hadasti, "New City," *i.e.*, Citium), "servant of Hiram king of the Sidonians to Baal of Lebanon," showing that this Hiram II. was not only king of Tyre, as the Assyrian inscription calls him, but of Sidon too; and further, that by this time Tyre has established a colony in Cyprus (*q.v.*). In Tiglath-pileser's Philistine campaign of 734 Byblus and Aradus paid tribute, and a king of Tyre, Metten, was forced to do the same (*KB.* ii. 23). For the period which follows a certain amount of information is furnished by Menander (in Jos., *Ant.*, ix. 14, 2). Elulaeus IX., in Assyrian Lulī, who ruled under the name of Pylas, was king of Tyre, Sidon, and other cities at this time (*c.* 725–690), and at the beginning of his reign suffered from an invasion by Shalmaneser IV.; this was probably the expedition against Hoshea of Samaria in 725; "the king of Assyria . . . overran all Phoenicia, but soon made peace with them all and returned back." In the reign of Sargon Phoenicia itself seems to have been left alone, though Cyprus submitted to him in 709; but in the reign of Sennacherib Elulaeus joined the league of Philistia and Judah, in alliance with Egypt and Ethiopia, which aimed at throwing off the oppressive tyranny of Assyria. In the great campaign of 701 Sennacherib came down upon the revolting provinces; he forced Lulī, king of Sidon, to fly for refuge to Cyprus, took his chief cities, and set up Tuba'lu (Ethbaal) as king, imposing a yearly tribute (*KB.* ii. 91). The blockade of Tyre by sea, significantly passed over in Sennacherib's inscription, is described by Menander; the Assyrian king, however, so far accomplished his object as to break up the combination of Tyre and Sidon, which had grown into a powerful state. At Sidon the successor of Ethbaal was Abd-milkath; in alliance with a Cilician chief he rebelled against Esarhaddon about the year 678, with disastrous consequences. Sidon was annihilated; Abd-milkath fell into the hands of Esarhaddon, who founded a new Sidon on the mainland, peopled it with foreigners, and called it after his own name. The old name, however, survived in popular usage; but the character of the city was changed, and till the time of Cyrus the kingdom of Sidon ceased to exist (*KB.* ii. 125 *seq.*, 145; *KAT*³., 88). Tyre also came in for its share of hardship. Elulaeus was followed by Baal, who in 672 consented to join Tirhaka, the Ethiopian king of Egypt, in a rebellion against Assyria. Esarhaddon, on his way to Egypt for the second time, blockaded Tyre, but he did not capture the city itself. His monument found at Zenjirli represents the great king holding Baal of Tyre and Tirhaka of Egypt by cords fastened in their lips; there is no evidence, however, that he actually took either of them prisoner (Gressmann, *Texte u. Bilder*², ii. Pl. lxiii.). Early in the reign of Assur-bani-pal Tyre was besieged again (668), but Assur-bani-pal succeeded no better than his predecessors. Nevertheless Baal submitted in the end, along with the princes of Gebal and Arvad, Manasseh of Judah, and the other Canaanite chiefs; in the island of Cyprus the Assyrians carried all before them (*KB.* ii. 149 *seq.*, 169, 173). On his return from the Arabian campaign Assur-bani-pal severely punished the rebellious inhabitants of Ushu (Palaetyrus) and Akko (*ibid.*, 229). In Phoenicia, as elsewhere, Assyrian rule created nothing and left nothing behind it but a record of barbarous conquest.

The Neo-Babylonian Period, 605–538 B.C.—In the last crisis of the dying power of Assyria the Egyptians for a short time laid hands on Phoenicia; but after their defeat at the battle of Carchemish (605), the Chaldaeans became the masters of western Asia. Jeremiah's allusion (xxv. 22) in 604 to the approaching downfall of the kings of Tyre and Sidon and the coastland beyond the sea, *i.e.*, the Phoenician settlements on the Mediterranean, seems to imply that the Phoenician states recovered some measure of independence; if they did it cannot have lasted long. In 588 Apries (Pharaoh Hophra) made an attempt to displace the Chaldaean supremacy; he defeated Tyre and Sidon, and terrorized the other cities into submission (Herod., ii. 161; Diod. Sic., i. 68). Some of the Phoenician chiefs, among them Ithobal II., the new king of Tyre, while forced to yield to a change of masters, were bold enough to declare their hostility to the Babylonians. This state of affairs did not escape the vigilance of Nebuchadrezzar. After the fall of Jerusalem he marched upon Phoenicia; Apries withdrew his army, and the siege of Tyre began. For 13 years the great merchant city held out (585–573; Jos., *c. Ap.*, i. 21: *cf.* Ezek. xxvi. 1 *seq.*). Ezekiel says that Nebuchadrezzar and his host had no reward for their heavy service against Tyre, and the presumption is that the city capitulated on favourable terms; for Ithobal's reign ends with the close of the siege, and the royal family is subsequently found in Babylon. The king appointed by Nebuchadrezzar was Baal II. (574–564), after whose death a republic was formed under a single suffete or "judge" (*shōfēt*). Josephus (*loc. cit.*) is again our authority for the changes of government which followed until the monarchy was revived. At length under Hiram III. Phoenicia passed from the Chaldaeans to the Persians (538), and at the same time Amasis II. of Egypt occupied Cyprus (Herod., ii. 182). There seems to have been no struggle; the great siege and the subsequent civil disorders had exhausted Tyre, and Sidon took its place as the leading state. About this time, too, Carthage made an effort for independence under Hanno the Great (538–521), the real founder of its fortunes; the old dependence upon Tyre was changed for a mere relation of piety observed by the annual sending of delegates (θεωροί) to the festival of Melkarth (Arrian, ii. 24; Polyb., xxxi. 20, 12). The disasters which befell Tyre during this and the foregoing period might suggest that its prosperity had been seriously damaged. But Tyre always counted for

more in commerce than in politics; and in the year 586, just before the great siege, Ezekiel draws a vivid picture (ch. xxvii.) of the extent and splendour of its commercial relations.

Constitution.—At this point it is convenient to mention what little is known about the constitution of the Phoenician states. All Canaanite analogy speaks for kingship as the oldest form of Phoenician government. In the native inscriptions the chief of the city in Phoenicia itself and in Cyprus is always called king. The royal houses claimed divine descent, and the king could not be chosen outside their members. His power, however, was limited by the wealthy merchant families, who possessed great influence in public affairs. The priest of Melkarth at Tyre was the second man in the kingdom. Associated with the prince was a council of elders; such was the case at Gebal (Byblus) from the earliest times to the latest (Ezek. xxvii. 9); at Sidon this council consisted of 100 members (Diod., xvi. 45), perhaps also at Tyre (*NSI.* p. 129). Inscriptions of the 3rd and 2nd centuries B.C. mention a *Rab* (chief) in Sidon, Cyprus and Gaulus (Gozo); what his position was it is difficult to say; in the colonies he may have been a district governor. During Nebuchadrezzar's time, as we have seen, a republic took the place of the monarchy at Tyre, and the government was administered by a succession of suffetes (judges); they held office for short terms, and in one instance two ruled together for six years. Much later, in the 3rd century B.C. an inscription from Tyre mentions a suffete (*NSI.* No. 8) without adding more to our knowledge. Carthage, of course, was governed by two suffetes, and these officers are frequently named in connection with the Carthaginian colonies (*NSI.* p. 115 *seq.*); but we must be careful not to draw the inference that Phoenicia itself had any such magistrates. Under the Persians a federal bond was formed comprising Sidon, Tyre and Aradus, whose duty it was to contribute 300 triremes to the Persian fleet (Herod., vii. 89), the lesser towns being under the command of the great cities. But federation on a larger scale was never possible in Phoenicia, for the reason that no sense of political unity existed to bind the different states together. Commercial interests dominated everything else, and while these stimulated a municipal life not without vigour, civil discipline and loyalty were but feebly felt. On occasion the towns could defend their independence with strenuous courage; the higher qualities which make for a progressive national life the Phoenicians did not possess.

The Persian Period, 538–333 B.C.—Phoenicia now became part of the fifth satrapy of the Persian empire, and entered upon a spell of comparative peace and growing prosperity. At this period Sidon occupied the position of leading state; in the fleet her king ranked next to Xerxes and before the king of Tyre (Herod., viii. 67); her situation afforded advantages for expansion which Tyre on its small and densely populated island could not rival. In the first half of the 4th century Straton I. (in Phoen. *'Abd-'ashtart* or *Bod-'ashtart*) was king, *c.* 374–362. He cultivated friendly relations with Athens, indicated in a decree of *proxenia* (Michel, *Rec. d'inscr. gr.* No. 93=*CIG.* No. 87); and the extent to which phil-Hellenic tendencies prevailed at this time in Sidon is shown by the royal sarcophagi, noble specimens of Greek art, which have been excavated in the necropolis of the city. It was in the reign of Straton that Tyre fell into the hands of Evagoras, king of Salamis, who had already supplanted Phoenician with Greek civilization in Cyprus (Isocr., *Evag.*, 62, *Paneg.*, 161; Diod. xv. 2). Straton made friends with Nicocles, son of Evagoras, and with him came to an untimely end through their implication in the great revolt of the satraps, 362 B.C. A new revolt of Sidon against the Persians took place under King Tennes; with the aid of Nectanebus of Egypt, the Sidonians carried the rest of Phoenicia with them and drove the satraps of Syria and Cilicia out of the country. Tennes, however, betrayed his people and opened the city to Artaxerxes III.; then he was executed after he had served the ends of the great king (346 B.C.; Diod., xvi. 41–45). The last king of Sidon was Straton II. ('Abd-'ashtart, 346–332) before the Persian empire came to an end.

Towards the close of the 5th century the Phoenician coins begin to supplement our historical sources. From the time of Darius the Persian monarchs allowed their satraps and vassal states to coin silver and copper money at discretion. Hence Aradus, Byblus, Sidon and Tyre issued a coinage of their own, of which many specimens exist; the coins are stamped as a rule with the emblem or name of the city, sometimes with the ruler's name. Thus from the coins of Byblus we learn the names of four kings, 'El-pa'al, 'Az-ba'al (between 360 and 340 B.C.), Adar-melek, 'Ain-el; from the coins of the other cities it is difficult to obtain much information. The native inscriptions, however, now become available, though most of them belong to the period which follows, and only a few have been discovered in Phoenicia itself. One of the earliest of these is the inscription of Byblus (*CIS.* i. 1=*NSI.* No. 3), dating from the Persian period; it records a dedication made by Yeḥaw-milk, king of Gebal, and mentions the name of the king's grandfather, Urimilk, but the exact dates of their reign are not given.

The Macedonian Period, 333–369 B.C.—When Alexander the Great entered Phoenicia after the battle of Issus (333 B.C.), the kings were absent with the Persian fleet in the Aegean; but the cities of Aradus, Byblus and Sidon welcomed him readily, the last-named showing special zeal against Persia. The Tyrians also offered submission, but refused to allow the conqueror to enter the city and sacrifice to the Tyrian Heracles. Alexander was determined to make an example of the first who should offer opposition, and at once began the siege. It lasted seven months. With enormous toil the king drove out a mole from the mainland to the island and thus brought up his engines; ships from the other Phoenician towns and from Cyprus lent him their aid, and the town at length was forced in July 332; 8,000 Tyrians were slain, 30,000 sold as slaves, and only a few notables, the king Azemilkos, and the festal envoys from Carthage who had taken refuge in the sanctuary of Melkarth, were spared (Diod., xvii. 40–46). It is not unlikely that Zech. ix. 2–4 refers to this famous siege. For the time Tyre lost its political existence, while the foundation of Alexandria presently changed the lines of trade, and dealt a blow even more fatal to the Phoenician cities.

During the wars of Alexander's successors Phoenicia changed hands several times between the Egyptian and the Syrian kings. From the year 275 "the people of Tyre" reckoned their era (*CIS.* i. 7=*NSI.* No. 9, *cf.* 10). The Tyrian coins of the period, stamped with native, Greek and Egyptian symbols, illustrate the traditional relations of the city and the range of her ambitions. A special interest attaches to these silver tetradrachms and didrachms because they were used by the Jews for the payment of the temple tax as "shekels of the sanctuary" (*NSI.* pp. 351, 44).

Among the Phoenician states we know most about Sidon during this period. The kingship was continued for a long time. The story goes that Alexander raised to the throne a member of the royal family, Abdalonymus, who was living in obscure poverty and working as a gardener (Justin, xi. 10; Curt., iv. 1; Diod., xvii. 47 wrongly connecting the story with Tyre). In 312 Ptolemy, then master of Phoenicia, appointed his general Philocles king of the Sidonians, and a decree in honour of this king has been found at Athens (Michel, No. 387, *cf.* 1,261); but he cannot have reigned long. For at the end of the 4th and the beginning of the 3rd century we have evidence of a native dynasty in the important inscriptions of Tabnith, Eshmun'azar and Bod-'ashtart, and in the series of inscriptions (repeating the same text) discovered at Bostan esh-Shēkh near Sidon (*NSI.* Nos. 4, 5, 6 and App. i.). With Bod-'ashtart, so far as we know, the dynasty came to an end, say about 250 B.C.

After the death of Antiochus IV. Epiphanes in 164 B.C., the kingdom of the Seleucids began to collapse. Berytus was destroyed by the usurper Trypho in 140 B.C. Tyre in 120 and Sidon in 111 received complete independence, and inaugurated new eras from these dates. Byblus and Tripolis fell into the hands of "tyrants" (Strabo, xvi. 2, 18; Jos., *Ant.*, xiv. 3, 2); from 83–69 B.C. the entire kingdom was held by the Armenian Tigranes.

Roman Rule.—At last in 64 B.C. Pompey arrived upon the scene and established order out of chaos. Phoenicia was incorporated into the Roman province of Syria; Aradus, Sidon, Tyre and Tripolis were confirmed in their rights of self-government and in

the possession of their territories. Under the beneficent government of Rome the chief towns prospered and extended their trade; but the whole character of the country underwent a change. During the Macedonian period Greek influences had been steadily gaining ground in Phoenicia; relations with the Greek world grew closer; the native language fell into disuse, and from the beginning of the Roman occupation Greek appears regularly in inscriptions and on coins, though on the latter Phoenician legends do not entirely vanish till the 2nd century A.D.; while the extent to which Hellenic ideas penetrated the native traditions and mythologies is seen in the writings of Philo of Byblus. For the purposes of everyday life, however, the people spoke not Greek, but Aramaic. As elsewhere, the Roman rule tended to obliterate characteristic features of national life, and under it the native language and institutions of Phoenicia became extinct.

Navigation, Trade, Colonies.—The Phoenicians were essentially a seafaring nation. Fearless and patient navigators, they ventured into regions where no one else dared to go, and, always with an eye to their monopoly, they carefully guarded the secrets of their trade routes and discoveries, and their knowledge of winds and currents. At the beginning of the 7th century B.C. a Phoenician fleet is said to have circumnavigated Africa (Herod., iv. 42). To the great powers Phoenician ships and sailors were indispensable; Sennacherib, Psammetichus and Necho, Xerxes, Alexander, all in turn employed them for their transports and sea-fights. Even when Athens had developed a rival navy Greek observers noted with admiration the discipline kept on board the Phoenician ships and the skill with which they were handled (Xen., *Oec.*, viii.); all the Phoenician vessels from the round merchant-boat (γαῦλος—after which the island of Gaulus, now Gozo, near Malta, was called) to the great Tarshish-ships, the "East-Indiamen" of the ancient world, excelled those of the Greeks in speed and equipment. As E. Meyer points out, the war between the Greeks and the Persians was mainly a contest between the sea-powers of Greece and Phoenicia. At what period did Phoenicia first rise to be a power in the Mediterranean? We are gradually approaching a solution of this obscure problem. Recent discoveries in Crete (*q.v.*) have brought to light the existence of a Cretan or "Minoan" sea-power of remote antiquity, and it is clear that a great deal of what used to be described as Phoenician must receive quite a different designation. The Minoan sea-power was at last broken up by invaders from the north, and a Carian rule became dominant in the Aegean (Herod., i. 171; Thucyd., i. 4, 8). It was a time of disorder and conflict due to the immigration of new races into the ancient seats of civilization, and it synchronized with the weakening of the power of Egypt in the countries which bordered on the eastern Mediterranean. This was in the 12th century B.C. The Tyrian trader saw that his opportunity was come, and the Aegean lay open to his merchant vessels. Where much is still obscure, all that seems certain is that the antiquity of Phoenicia as a sea- and trading-power has been greatly exaggerated both in ancient and in modern times; the Minoan power of Cnossus preceded it by many centuries; the influence of Phoenicia in the Aegean cannot be carried back much earlier than the 12th century B.C.

A vivid description of the Phoenicians' trade at the time of Tyre's prosperity is given by Ezekiel (xxvii. 12–25), and it shows how extensive were their commercial relations not only by sea, but by land as well. It was they who distributed to the rest of the world the wares of Egypt and Babylonia (Herod., i. 1). From the lands of the Euphrates and Tigris regular trade-routes led to the Mediterranean with trading-stations on the way, several of which are mentioned by Ezekiel (xxvii. 23). In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the 22nd and 23rd dynasties (825–650 B.C.), when all other foreign merchants were frightened away. Though there were never any regular colonies of Phoenicians in Egypt, the Tyrians had a quarter of their own in Memphis (Herod., ii. 112). The Arabian caravan-trade in perfume, spices and incense passed through Phoenician hands on its way to Greece and the west (Herod., iii. 107). Between Israel and Phoenicia the relations naturally were close; the former provided certain necessaries of life, and received in exchange articles of luxury and splendour (Ezek. xxvii. 16–18). Israelite housewives sold their homespun to Phoenician pedlars (Prov. xxxi. 24 R.V.M.); in Jerusalem Phoenician merchants and money lenders had their quarter (Zeph. i. 11), and after the Return we hear of Tyrians selling fish and all manner of ware in the city (Neh. xiii. 16), and introducing other less desirable imports, such as foreign cults (Isa. lxv. 11). The Phoenician words which made their way into Greek at an early period indicate the kind of goods in which the Phoenicians traded with the west, or made familiar through their commerce; the following are some of them—χρυσός, χιτών, βύσσος, ὀθόνη, μύῤῥα, νάβλα, κύπρος, φῦκος, μνᾶ, παλλακίς, βαίτυλος. Another article of commerce which the Phoenicians brought into the market was amber.

The Phoenician colonies were all supposed to have been founded from Tyre: with regard to the colonies in Cyprus and north Africa this was undoubtedly true. Cyprus possessed resources of timber and copper which could not fail to tempt the keen-eyed traders across the water, who made Citium (from Kittim, the name of the original non-Semitic inhabitants) their chief settlement, and thence established themselves in Idalium, Tamassus, Lapethus, Larnaka, Qarth-ḥadasht (Karti-hadasti) and other towns. In the inscriptions of the 4th to 3rd centuries, the Phoenician potentates in the island call themselves "kings of Kition and Idalion" (*N.S.I.* pp. 55–89).

Homer represents the Phoenicians as present in Greek waters for purposes of traffic, but not as settlers (*Il.*, xxiii. 744). They occupied trading-stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex, of which an enormous supply was needed for the dyeing industry; specially famous was the purple of the Laconian waters, the isles of Elishah of Ezek. xxvii. 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Greek world the Phoenicians made themselves heartily detested by their passion for gain (Plato, *Rep.* iv. 436 A.).

Farther west in the Mediterranean Phoenician settlements were planted first in Sicily, at Heraclea or Ras Melqarth; the islands between Sicily and Africa, Melita (Malta) on account of its valuable harbour, Gaulus and Cossura were also occupied (Diod., v. 12); and a beginning was made with the colonization of Sardinia and Corsica; but farther west still more permanent colonies were established. It was the trade with Tarshish; *i.e.*, the region of Tartessus in south-west Spain, which contributed most to the Phoenicians' wealth; it was said that even the anchors of ships returning from Spain were made of silver (Diod., v. 35). From Gadeira (Punic *Gādēr*, Lat. *Gades*, now Cadiz), the Sidonian ships ventured farther on the ocean and drew tin from the mines of north-west Spain or from the richer deposits in the Cassiterides; *i.e.*, the Tin Islands. These were discovered to be, not a part of Britain as was imagined at first, but a separate group by themselves, now known as the Scillies; hence it is improbable that the Phoenicians ever worked the tin-mines in Cornwall.

The rich trade with Spain led to the colonization of the West. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (i. 3, 2), in the period of Tyre's first expansion. Lixus in Mauretania, Gades and Utica, are said to have been founded, one after the other, as far back as the 12th century B.C. Most of the African colonies were no doubt younger; we have traditional dates for Aoza (887–855) and Carthage (813). A large part of north-west Africa was colonized from Phoenicia; owing to these first settlers, and after them to the Carthaginians, the Phoenician language became the prevailing one, and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies, which, unlike those of Greece, remained subject to the mother-city, and paid tithes of their revenues to its chief god, Melqarth, and sent envoys annually to his feast. Then at the beginning of the 8th century B.C. the colonial power of Tyre began to decline; on the mainland and in Cyprus the Assyrians

gained the upper hand; in the Greek islands the Phoenicians had already been displaced to a great extent by the advancing tide of Dorian colonization. But as Tyre decayed in power the colonies turned more and more to Carthage as their natural parent and protector. For effective control over a colonial empire Carthage had the advantage of situation over far-away Tyre; the traditional bonds grew lax and the ancient dues ceased to be paid, though as late as the middle of the 6th century Carthage rendered tithes to the Tyrian Melqarth. And the mother-country cherished its claims long after they had lost reality; in the 2nd century B.C., for example, Sidon stamped her coins with the legend, "Mother of Kambē (*i.e.*, Carthage), Hippo, Kition, Tyre" (*NSI*. p. 352).

Manufactures, Inventions, Art.—From an early date the towns of the Phoenician coast were occupied, not only with distributing the merchandise of other countries but with working at industries of their own; especially purple-dyeing and textile fabrics (*Il.*, vi. 289 *sqq.*), metal work in silver, gold and electrum (*Il.*, xxiii. 741 *sqq.; Od.*, iv. 615 *sqq.* xv. 458 *sqq.*), and glass-work, which had its seat at Sidon. The iron and copper mines of Cyprus (not Sidon, as Homer implies, *Od.*, xv. 424) furnished the ore which was manufactured into articles of commerce. Egyptian monuments frequently mention the vessels of gold and silver, iron and copper, made by the Dahi, *i.e.*, the Phoenicians (W. M. Müller, *As. u. Eur.*, 306); and in Cyprus and at Nimrud bronze and silver paterae have been found, engraved with Egyptian designs, the work of Phoenician artists (*see* table-cases C and D in the Nimrud gallery of the Brit. Mus.). The invention of these various arts and industries was popularly ascribed to the Phoenicians, no doubt merely because Phoenician traders brought the products into the market. But dyeing and embroidery probably came from Babylon in the first instance; glass-making seems to have been borrowed from Egypt; the invention of arithmetic and of weights and measures must be laid to the credit of the Babylonians. The ancients believed that the Phoenicians invented the use of the alphabet (*e.g.*, Pliny, *N.H.*, v. 13, *cf.* vii. 57; Lucan, *Bell. Civ.*, iii. 220 *seq.*); but it is unlikely that any genuine tradition on the subject existed, and though the Phoenician theory has found favour in modern times it is open to much question.

The art of Phoenicia is characterized generally by its dependence upon the art of the neighbouring races. It struck out no original line of its own, and borrowed freely from foreign, especially Egyptian, models. Remains of sculpture, engraved bronzes and gems, show clearly the source to which the Phoenician artists went for inspiration; for example, the uraeus-frieze and the winged disc, the *ankh* or symbol of life, are Egyptian designs frequently imitated. It was in the times of the Persian monarchy that Phoenician art reached its highest development, and to this period belong the oldest sculptures and coins that have come down to us. A characteristic specimen of the former is the stele of Yeḥaw-milk, king of Gebal (*CIS*. i. 1), in which the king is represented in Persian dress, and the goddess to whom he is offering a bowl looks exactly like an Egyptian Isis-Hathor; (Gressmann, *Texte u. Bilder*², ii. Pl. ccviii.). The whole artistic movement in Phoenicia may be divided into two great periods: in the first, from the earliest times to the 4th century B.C., Egyptian influence and then Babylonian or Asiatic influence is predominant, but the national element is strongly marked; while in the second, Greek influence has obtained the mastery, and the native element, though making itself felt, is much less obtrusive. Throughout these periods works of art, such as statues of the gods and sarcophagi, were imported direct at first from Egypt and afterwards mainly from Rhodes. The finest sarcophagi that have been found in the necropolis of Sidon (now in the Imperial Museum, Constantinople) are not Phoenician at all, but exquisite specimens of Greek art. The Phoenicians spent much care on their burial-places, which have furnished the most important monuments left to us. Thus, on the site of Gebal, now Jebeil, the French excavators, under the leadership of Montet, 1921–23, have unearthed the fine sarcophagus of Aḥîram, Egyptian in style, and engraved with the earliest Phoenician inscripition so far known; *see* Gressmann; *Texte u. Bilder*², i. 440; ii. 189–192 and Pl. ccliv. (1927). Besides busts and figurines, which belong as a rule to the Greek period, the smaller objects usually found are earthen pitchers and lamps, glass-wares, tesserae and gems. Of buildings which can be called architectural few specimens now exist on Phoenician soil, for the reason that for ages the inhabitants have used the ruins as convenient quarries. Not a vestige remains of the great sanctuary of Melqarth at Tyre; a few traces of the temple of Adonis near Byblus were discovered by Renan, and a peculiar mausoleum, Burj al-Bezzāq, is still to be seen near Amrit; excavations at Bostan esh-Shēkh near Sidon revealed parts of the enclosure or foundations of the temple of Eshmun (*NSI*. p. 401); the conduits of Ras el- 'Ain, south of Tyre, are considered to be of ancient date.

Religion.—Like the Canaanites of whom they formed a branch, the Phoenicians connected their religion with the great powers and processes of nature. The gods whom they worshipped belonged essentially to the earth; the fertile field, trees and mountains, headlands and rivers and springs, were believed to be inhabited by different divinities, who were therefore primarily local, many in number, with no one in particular supreme over the rest. It seems, however, that as time went on some of them acquired a more extended character; thus Ba'al and Astarte assumed celestial attributes in addition to their earthly ones, and the Tyrian Melqarth combined a celestial with a marine aspect. The gods in general were called *'elōnīm, 'elīm;* Plautus uses *alonium valonuth* for "gods and goddesses" (*Poen.*, v. I, 1). These plurals go back to the singular form 'El, the common Semitic name for God; but neither the singular nor the plural is at all common in the inscriptions (*NSI*. pp. 24, 41, 51); 'El by itself has been found only once; the fem. 'Elath is also rare (*ibid.*, pp. 135, 158). The god or goddess was generally called the Ba'al or Ba'alath of such and such a place, a title which was used not only by the Canaanites, but by the Aramaeans (Be'el) and Babylonians (Bel) as well. There was no one particular god called Ba'al; the word is not a proper name but an appellative, a description of the deity as *owner* or *mistress;* and the same is the case with Milk or Melek, 'Adon, 'Amma, which mean *king, lord, mother*. The god himself was unnamed or had no name. Occasionally we know what the name was; the Ba'al of Tyre was Melqarth which again means merely "king of the city"; similarly among the Aramaeans the Ba'al of Harran was the moon-god Sin. As each city or district had its own Ba'al, the "husband" of the land which he fertilized, so there were many Ba'als, and the Old Testament writers could allude to the Ba'ālim of the neighbouring Canaanites. Sometimes the god received a distinguishing attribute which indicates an association not with any particular place, but with some special characteristic; the most common forms are Ba'al-ḥammān, the chief deity of Punic north Africa perhaps "the glowing Ba'al," the god of fertilizing warmth, and Ba'al-shamēm, "Ba'al of the heavens" (*cf.* Dan. xii. 11, xi. 31, etc.). The latter deity was widely venerated throughout the north Semitic world; his name, which does not appear in the Phoenician inscriptions before the 3rd century B.C., goes back at least to 800 B.C. (Aramaic inscription of Zakir, from Hamath.) The worship of the female along with the male principle was a strongly marked feature of Phoenician religion.

To judge from earliest evidence on the subject, the Ba'alath of Gebal or Byblus, referred to again and again in the Amarna letters (*Bêlit ša Gubla*, Nos. 68–125), must have been the most popular of the Phoenician deities, as her sanctuary was the oldest and most renowned. The *mistress of Gebal* was no doubt 'Ashtart (Astartē in Greek, 'Ashtōreth in the Old Testament, pronounced with the vowels of *bōsheth*, "shame"), a name which is obviously connected with the Babylonian Ishtar, and, as used in Phoenician, is practically the equivalent of "goddess." She represented the principle of fertility and generation; the common epithets Κύπρις and Κυθέρεια (of Kuthera in Cyprus), Cypria and Paphia, show that she was identified with Aphrodite and Venus. Though not primarily a moon-goddess, she sometimes appears in this character (Lucian, *Dea syr*, § 4; Herodian v. 6, 10), and Herodotus describes her temple at Ashkelon as that of the heavenly

Aphrodite (i. 105). We find her associated with Ba'al and called "the name of Ba'al"; *i.e.*, perhaps his manifestation. Another goddess, specially honoured at Carthage, is Tanith (pronunciation uncertain); nothing is known of her characteristics; she is regularly connected with Ba'al on the Carthaginian votive tablets, and called "the face of Ba'al"; *i.e.*, his representative or revelation, though again some question this rendering as too metaphysical, and take "face of Ba'al" to be the name of a place, like Peni'el ("face of 'El"). Two or three other deities may be mentioned here: Eshmun, the god of vital force and healing, worshipped at Sidon especially, but also at Carthage and in the colonies, identified by the Greeks with Asclepius; Melqarth, the patron deity of Tyre, identified with Heracles; Reshef or Reshūf, the "flame" or "lightning" god, especially popular in Cyprus and derived originally from Syria, whom the Greeks called Apollo. A tendency to form a distinct deity by combining the attributes of two produced such curious fusions as Milk-'ashtart, Milk-ba'al, Milk-'osir, Eshmun-melqarth, Melqarth-reṣef, etc. As in the case of art and industries so in religion the Phoenicians readily assimilated foreign ideas. The influence of Egypt was specially strong (*NSI.* pp. 62, 69, 148, 154). The Phoenician settlers at the Peiraeus worshipped the Assyrian Nergal, and their proper names are compounded with the names of Babylonian and Arabian deities (*NSI.* p. 101). Closer intimacy with the Greek world naturally brought about modifications in the character of the native gods, which became apparent when Ba'al of Sidon or Ba'al-shamēm was identified with Zeus, Tanith with Demeter or Artemis, 'Anath with Athena, etc.; the notion of a supreme Ba'al, which finds expression in the Greek *βῆλος* and *βααλτίς* or *βήλθης* (the goddess of Byblus), was no doubt encouraged by foreign influences. On the other hand, the Phoenicians produced a considerable effect upon Greek and Roman religion, especially from the religious centres in Cyprus and Sicily. A great number of divinities are known only as elements in proper names, *e.g.*, *Sakun*-yathon (Sanchuniathon), 'Abd-*sasom*, *Ṣed*-yathon, and fresh ones are continually being discovered. It was the custom among the Phoenicians, as among other Semitic nations, to use the names of the gods in forming proper names and thus to express devotion or invoke favour; thus Ḥanni-ba'al, 'Abd-melqarth, Hanni-'ashtart, Eshmun-'azar. The proper names further illustrate the way in which the relation of man to God was regarded; the commonest forms are *servant* ('abd, *e.g.*, 'Abd-'ashtart), *member* or *limb* (bod, *e.g.*, Bodmelqarth), client or *guest* (ger, *e.g.*, Ger-eshmun); the religious idea of the *guest* of a deity had its origin in the social custom of extending hospitality to a stranger and in the old Semitic right of sanctuary.

Sacred Objects and Worship.—Probably like other Canaanites the Phoenicians offered worship "on every high hill and under every green tree"; but to judge from the allusions to sanctuaries in the inscriptions and elsewhere, the Ba'al or 'Ashtart of a place was usually worshipped at a temple, which consisted of a court or enclosure and a roofed shrine with a portico or pillared hall at the entrance. In the court sometimes stood a conical stone, probably the symbol of Astarte, as on the Roman coins of Byblus (*see* Ohnefalsch-Richter, *Cyprus*, pl. lvi., the temenos at Idalion). Stone or bronze images of the gods were set up in the sanctuaries (*NSI.* Nos. 13 *seq.*, 23–27, 30, etc.); and besides these the *baetylia* (meteoric stones) which were regarded as symbols of the gods. Pillars, again, had a prominent place in the court or before the shrine (*naṣab, ibid.* pp. 102 *seq.* and W. R. Smith, *Rel. of Sem*³., pp. 203 ff., 456 ff.); but it is not known whether the sacred pole (*'asherah*), an invariable feature of a Canaanite sanctuary, was usual in a Phoenician temple. The inscriptions mention altars of stone and bronze, and from the sacrificial tariffs which have survived we learn that the chief types of sacrifice among the Phoenicians were analogous to those which we find in the Old Testament (*NSI.* p. 117). The ghastly practice of sacrificing human victims was resorted to in times of great distress (*e.g.*, at Carthage, Diod., xx. 14), or to avert national disaster (Porphyry, *de Abstin*, ii. 56); it was regarded as a patriotic act when Hamilcar threw himself upon the pyre after the disastrous battle of Himera (Herod., vii. 167). The god who demanded these victims, and especially the burning of children, seems to have been Milk, the Molech or Moloch of the Old Testament. In this connection may be mentioned the custom of burning the chief god of the city in effigy, or in the person of a human representative, at Tyre and in the Tyrian colonies, such as Carthage and Gades; the custom lasted down to a late time (*see* Frazer, *Adonis, Attis, Osiris*, ch. v.). Another horrible sacrifice was regularly demanded by Phoenician religion: women sacrificed their virginity at the shrines of Astarte in the belief that they thus propitiated the goddess and won her favour (*Rel. of Sem*³., 329, 611 ff.); licentious rites were the natural accompaniment of the worship of the reproductive powers of nature. These temple prostitutes are called *qedēshīm qedēshōth, i.e.*, sacred men, women, in the Old Testament (Deut. xxiii. 18; I Kings xiv. 24, etc.). Other persons attached to a temple were priests, augurs, sacrificers, barbers, officials in charge of the curtains, masons, etc. (*NSI.* No. 20); we hear also of religious gilds and corporations, perhaps administrative councils, associated with the sanctuaries (*ibid.*, pp. 94, 121, 130, 144 *seq.*).

Mythology and Religious Ideas.—No doubt the Phoenicians had their legends and myths to account for the origin of man and the universe; to some extent these would have resembled the ideas embodied in the book of Genesis. Two cosmogonies have come down to us which, though they differ in details are fundamentally in agreement. The one, of Sidonian origin, is preserved by Damascius (*de prim. principiis*, 125) and received at his hands a Neoplatonic interpretation; the other and more elaborate work was composed by Philo of Byblus (temp. Hadrian); he professed that he had used as his authority the writings of Sanchuniathon (*q.v.*), an ancient Phoenician sage, who again derived his information from the mysterious inscribed stones (*ἀμμουνεῖς* = חמנים, i.e., images or pillars of Ba'al-ḥammān) in the Phoenician temples. Philo's cosmogony has been preserved, at least in fragments, by Eusebius in *Praep. evang.*, vol. i. (*Fr. hist. gr.*, iii. 563 *sqq.*). It cannot, however, be taken seriously as an account of genuine Phoenician beliefs. At the same time Philo did not invent all the nonsense which he has handed down; he drew upon various sources, Greek and Egyptian, some of them ultimately of Babylonian origin, and incidentally, he mentions matters of interest which, when tested by other evidence, are fairly well supported. He shows at any rate that some sort of a theology existed in his day; particularly interesting is his description of the symbolic figure of Cronus with eyes before and behind and six wings open and folded (*Fr. hist. gr.*, iii. 569), a figure which is represented on the coins of Gebal-Byblus (2nd century B.C.) as the mythical founder of the city. It is evident that the gods were regarded as being intimately concerned with the lives and fortunes of their worshippers. The vast number of small votive tablets found at Carthage prove this; they were all inscribed by grateful devotees "to the lady Tanith, Face of Ba'al, and the lord Ba'al-ḥammān, because he heard their voice." The care which the Phoenicians bestowed upon the burial of the dead has been alluded to above; pillars (*maṣṣēbōth*) were set up to commemorate the dead among the living (e.g., *NSI.* Nos. 18, 19, 21, 32); if there were no children to fulfil the pious duty, a monument would be set up by a man during his lifetime (*ibid.*, No. 16; *cf.* 2 Sam. xviii. 18). Any violation of the tomb was regarded with the greatest horror (*ibid.*, Nos. 4, 5). The grave was called a resting-place (*ibid.*, Nos. 4, 5, 16, 21), and the departed lay at rest in the underworld with the *Refāim*, the weak ones (the same word and idea in the Old Testament, Isa. xiv. 9, xxvi. 14, 19; Job xxvi. 5; Ps. lxxxviii. 10 etc.). The curious notion prevailed, as it did also among the Greeks and Romans, that it was possible to communicate with the gods of the underworld by dropping into a grave a small roll of lead (*tabella devotionis, NSI.* No. 50), inscribed with the message, generally a curse, which it was desired to convey to them.

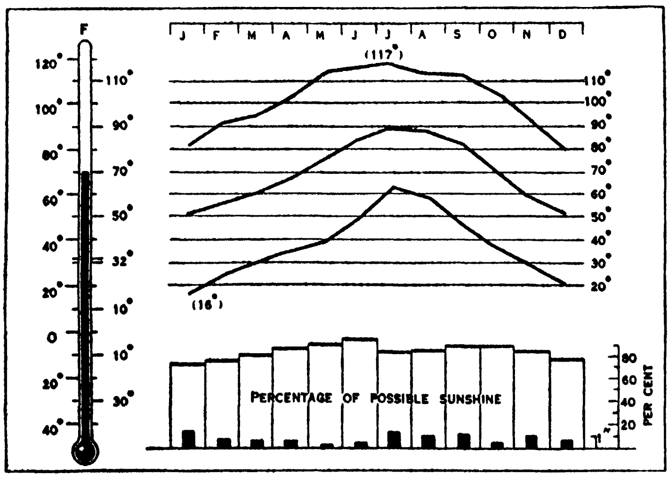
PHOENIX, the capital and largest city of Arizona, U.S.A., and the county-seat of Maricopa county; on the Salt river, at an altitude of 1,100 ft., midway between El Paso and Los Angeles.



WEATHER GRAPH OF PHOENIX, ARIZONA. THE MERCURY INDICATES THE NORMAL ANNUAL MEAN TEMPERATURE, AND THE CURVES SHOW THE MONTHLY MAXIMUM, AVERAGE AND MINIMUM MEAN TEMPERATURES. THE BLOCK SHOWS THE POSSIBLE SUNSHINE PERCENTAGE, AND THE SHADED SPOTS INDICATE THE NORMAL MONTHLY PRECIPITATION

It is on Federal highways 80 and 89; has a municipal airport; and is served by the Santa Fe and the Southern Pacific railways. The population was 29,053 in 1920 (81% native white) and was estimated locally at 65,000 in 1928. The climate of the Salt River valley is mild, dry, and clear, and Phoenix is an important health and pleasure resort. The average monthly mean temperature ranges from 51·2° F in December to 89·8° in July; the average annual precipitation is 7·87 inches; the amount of "possible sunshine" averages 84%. It is estimated that tourists spend $3,000,000 in the city in a year. The city occupies 5·75 sq.m. in a vast saucer-like valley, encircled by mountains, which is irrigated from the Roosevelt dam, 70 m. N.E., and other projects. Cotton (largely a long-staple variety), alfalfa, lettuce, cantaloupes, grapes, citrus fruits, olives, apricots, and other fruits and vegetables are leading crops. Date palms, pepper and eucalyptus trees, and the magnificent saguaro cactus, are features of the landscape. The state capitol, of native tufa, is set in a 10-acre park where all the trees and shrubs indigenous to the region are represented. The Papago Saguaro National Monument (1,940 acres) lies 3 m. E.; 6 m. S. is the city's mountain park of 14,000 acres; at Tempe, 8 m. E., is a State Teachers' college; and the State experimental farm is near Mesa, 15 m. S.E. Phoenix has an assessed valuation of $57,625,882 (1928); bank deposits on June 30, 1928, aggregated $36,677,801; and post-office receipts for 1927 were $428,637. Since 1914 it has had a commission-manager form of government. Phoenix was founded in 1871, incorporated in 1881, and became the capital of Arizona in 1889. In 1890 the population was 3,152; in 1900, 5,544; in 1910, 11,134. Between 1910 and 1920 it increased 161%.

PHOENIX, a fabulous bird, sacred to the sun (Gr. Φοῖνιξ, apparently "bright-coloured"; φοῖνιξ also means "a palm-tree"). From statements in a large number of classical and post-classical authors, ranging from the 5th century B.C. (Herodotus, perhaps Hecataeus) to the Middle Ages (Isaac Tzetzes) the following account is obtained: The phoenix was a large bird of very gorgeous plumage, having, according to one or two authorities, a sweet voice. It was always male, the only one of its kind, and lived a long time (various authors give periods ranging from 500 years, the commonest account, up to 12,954; Tacitus, *Annales* vi. 28, 4, gives 1,461 years, which is an Egyptian Sothis period). At the expiration of that time it made itself a nest of twigs of spice-trees, on which it died, by setting the nest on fire and burning itself alive. From its body, or its ashes, or the nest, which it had fertilized, came forth another phoenix, either perfect or at first in the shape of a white grub. This young bird, as soon as it was strong enough, took up the body of its father, covered in spices, or the ashes, nest, and all, and flew to Heliopolis in Egypt, where it deposited them on the altar of the Sun. There are numerous variants in detail; sometimes the phoenix goes to Egypt to die, having produced its offspring before dying.

It was not doubted by the majority that the phoenix really was seen now and then in Egypt; Tacitus, *loc. cit.*, and Pliny, *nat. hist.*, x. 2, mention recorded appearances, genuine and otherwise. Attention is therefore drawn by A. Wiedemann to the facts that a bird of the stork kind, the *bennu* or *bannu,* was sacred at Heliopolis and connected with the local sun-worship, moreover, that its name also means a palm-tree. This certainly gives a plausible origin for some parts of the Greek story and accounts for Herodotus's statement (ii. 73, 1) that he saw a picture of it in Egypt; for the *bennu* is to be found on surviving monuments. But it fails to account for the persistent statement that the phoenix is not a native of Egypt, but lives in Arabia, Assyria, Ethiopia or India, nor does the real or pictured *bennu* at all resemble the phoenix as described. Hence it is likely that the ultimate origin of the story, however it may have reached Greece, is to be sought in the mythology of one or another of these countries.

Many commentators still understand the word חול, *chol,* in Job xxix. 18 (in King James's Version, "sand") to apply to the phoenix. This interpretation is perhaps as old as the (original) Septuagint, and is current with the later Jews. Among the Arabs the story of the phoenix was confused with that of the salamander; and the samand or samandal (Damiri, ii. 36 *et seq.*) is represented sometimes as a quadruped, sometimes as a bird. It was firmly believed in; for the incombustible cloths woven of flexible asbestos were popularly thought to be made of its hair or plumage, and were in fact, called by the same name (*cf.* Yaqut i. 529, and Dozy, *s.v.*). The *'anka* (Pers. *simurgh*), a stupendous bird like the roc (rukh) of Marco Polo and the *Arabian Nights,* also borrows some features of the phoenix. According to Kazwini (i. 420) it lives 1,700 years, and when a young bird is hatched the parent of opposite sex burns itself alive.

Ancient and modern authorities are collected and analysed by Türk, in Roscher's *Lexikon*, iii. col. 3,450 *et seq.*

PHOENIX ISLANDS: *see* PACIFIC ISLANDS.

PHOENIXVILLE, a borough of Chester county, Pennsylvania, U.S.A., on the Schuylkill river, at the mouth of French creek, 28 m. N.W. of Philadelphia; served by the Pennsylvania and the Reading railways. Pop. (1920) 10,484 (80% native white); 1928 local census 12,282. It has extensive iron and steel works, making steel bridges, architectural steel, boilers and many other products; also underwear, silk and silk hosiery mills. The aggregate manufactured output in 1925 was valued at $13,583,696. Phoenixville was settled in 1732 and incorporated in 1849.

PHOLIDOTA, an order of mammals, comprising only the scaly ant-eaters (Manidae) of Asia and Africa. The order was formerly united with the Xenarthra and Tubilidentata (*q.v.*) as the order Edentata (*q.v.*). (*See* also PANGOLIN.)

PHONETICS is the science of the pronunciation of languages. It is concerned with the mechanism by which speech-sounds are formed, the manner of combining sounds so as to make syllables, words and sentences, the treatment of speech-sounds in different languages as regards their "attributes" (length, stress and voice-pitch), the *timbre* (acoustic quality) of speech-sounds and groups of speech-sounds, the methods of representing speech-sounds by means of writing (including transcripts for language learners, spelling reform and the writing of languages hitherto unwritten).

Phonetics has two main practical objects: (1) to help learners of foreign languages to hear accurately and to pronounce accurately, and (2) to enable those who are concerned with the spelling or writing down of languages to devise the simplest and most practical system for each language.

Phonetic Analysis.—In order to effect either of these prac-

tical objects it is necessary that a "phonetic analysis" should be made of the language under consideration. The nature and mode of formation of every speech-sound of the language must be ascertained with the greatest possible accuracy; long passages of the language must then be transcribed phonetically by means of a minutely accurate system, with the object of finding out how the sounds may be grouped into "phonemes" (*see* p. 774). The usage of the particular language as regards the length of sounds, the stress (force-accent) of syllables and the intonation (pitch, musical accent) of words and sentences must be examined in detail. To obtain the best results, the investigations must be made by the "acoustic" method; the results may be corroborated by "experimental" methods.

Analysis by the "acoustic" method can only be carried out by an observer who is a trained phonetician, *i.e.*, a person whose ear has been trained to distinguish and recognize minute shades of sound and who has arrived at a high degree of precision in the control over the movements of his tongue and other parts of the speech-organs—who can in fact already pronounce a large number of difficult foreign sounds and sound-combinations. He must have as a collaborator a native speaker of the language to be analysed—if possible, one with natural linguistic ability. The process of investigation is as follows. The observer gets the native to repeat words and phrases of his language a very large number of times. He may find these words and phrases to be composed of sounds already known to him. If so (and if the language does not present special difficulties in the matter of length, stress or intonation), he will at once be able to repeat them to the native's satisfaction. If the native is not satisfied, it means that the word or phrase contains one or more unfamiliar sounds, or that the language contains some unusual features of length, stress or intonation. To acquire the correct pronunciation, the observer uses his power of making fine adjustments in the positions and movements of his own speech organs. He tries one variation, and then another, until he succeeds in pronouncing the word or phrase to the native's satisfaction. He then knows by his own muscular and tactile sensations what is the exact manner of formation of the unfamiliar sounds of the language. The investigator must make his native collaborator understand that nothing short of pronunciation indistinguishable from that of a native is to be accepted. When necessary, he must test his native collaborator's ear by making intentional mispronunciations. The best results are of course obtained when the observer can train the native himself in methods of phonetic research.

Experimental Methods.—Analysis of pronunciation by the acoustic method may be checked by "experimental" methods, *i.e.*, investigation by apparatus. The most important pieces of apparatus are the gramophone, the phonograph, the phonetic kymograph and the lioretgraph (an instrument for enlarging the curves formed by the grooves of gramophone and phonograph records). They are particularly useful in the analysis of length and intonation. The ascertaining of the positions of the tongue and velum and of the shapes assumed by the pharyngeal cavity is facilitated by X-ray photography. Indications of tongue-positions may also be found by the use of a special kind of artificial palate.

Phonetics Applied to the Learning of Foreign Languages.—The following is a brief account of the method of using phonetics in learning a foreign language with the aid of a teacher. The task of the teacher is to make his pupil pronounce the foreign language correctly. Consequently his first aim must be to teach him to make the sounds of that language. This is done by imitation coupled with phonetic theory. Thus if the sound to be taught is the French sound of *u* in *lune,* and, as is usually the case, the English pupil is unable to make it correctly by imitation, the teacher tells the pupil to perform the following exercise, which is based on the theory of tongue and lip positions: Purse up the lips as for the English *oo*-sound, and while holding them in that position, try to pronounce the English *ee*-sound. With a very little practice the French sound of *u* will result. Again, if the pupil is to learn to make the sound ɬ (Zulu *hl,* Welsh *ll*), the teacher, knowing that the sound is a "voiceless l," tells him to keep his tongue as if he were going to say an ordinary l and then simply blow a strong stream of air through his mouth; this will give a good approximation to the sound, and it can be perfected by a knowledge of the details of the formation of l-sounds. If the pupil is to learn to make the German sound of *ch* in *recht,* the teacher, knowing that its tongue-position is almost identical with that of the English *ee*-sound, tells him to keep his tongue as if he were going to say the English *ee*-sound and then merely to blow out a stream of air. If he is to learn to make the Polish sound of *ć* or Pekingese sound written *hs,* the teacher tells him to try to make this German sound and *s* simultaneously, knowing that the attempt to do this will give the right tongue-position. The methods used in the above cases are very simple; in more difficult cases it is often necessary to try several methods before one is found which will enable the pupil to produce the correct sound.

Ear-training.—One of the most important parts of any course of instruction in phonetics consists of "ear-training" or more accurately "cultivation of the auditory memory." The pupil must learn (1) to *discriminate* between one foreign sound and another which on a first hearing may seem to resemble it; (2) to *discriminate* between foreign sounds and sounds of the mother tongue which resemble them; (3) to *remember* the acoustic qualities of foreign sounds; (4) to *recognize* foreign sounds with ease and certainty. There is only one method of training the auditory memory, namely "nonsense dictation." The teacher dictates meaningless words made up of sounds of the language to be learnt. The pupil writes what he thinks he hears by means of a phonetic system; then the teacher can see from the transcript whether the pupil has recognized the foreign sounds correctly. When the pupil makes a mistake, the teacher repeats the meaningless word firstly as he originally said it and then in the way written by the pupil; he repeats the two pronunciations a number of times so that the pupil may hear clearly the nature of his mistake. The pupil's course of study should include a large amount of this type of exercise carefully graduated. Thus if the pupil is learning the pronunciation of French, the earlier ear-training exercises would contain easy words such as the following: petozɛ, vɔʃɛnut, fɑkøna, sogɛ̃ʒib. The exercises become progressively more difficult until words are given such as: pfestriɔʒnwɛbm, uidznezmœrlɔ, bɑ̃ɔzvələlaʃkeɛ. (The system of transcription used here and elsewhere in this article is that of the *International Phonetic Association.*) Later on, the exercises are made still more difficult by the introduction of sounds of the pupil's mother tongue.

Phonetic Transcription.—Besides being able to hear the foreign sounds correctly and to make them correctly the pupil must know which are the appropriate sounds to use in words and sentences. This information is best conveyed to him by means of a phonetic notation, *i.e.*, by spelling the words and sentences with an alphabet which provides one letter for each phoneme (*see* p. 774) of the language. (In certain cases, in order to avoid introducing additional symbols, it is convenient to represent a sound by means of a digraph, *i.e.*, a sequence of two letters; thus the sounds of German *z* and English *ch* are commonly transcribed ts, tʃ.) The pupil's course of study should therefore include reading from phonetic texts and writing passages of the language phonetically as exercises to be corrected by the teacher. The pupil must also be instructed in the use made of length, stress and intonation in the foreign language. These features of the language should be marked as far as practicable in the phonetic transcriptions.

When the learner is unable to find a phonetically trained teacher of the language, he should make himself familiar with the principles of general phonetics, and thus learn to analyse his instructor's speech and reproduce it accurately. If there exists a good book on the phonetics of the language, he should be able to pronounce intelligibly with its aid. Good gramophone records may also be of considerable assistance.

Phonetics Applied to the Teaching of the Mother Tongue.—The "received" form of a language is a kind of foreign language to those who speak dialects or speak with special "accents." The

methods of teaching "received" pronunciation are therefore similar to those followed in teaching a foreign language. Some of the sounds of "received" pronunciation will be new to the pupil, and must be taught by means of exercises which his phonetically trained teacher invents to suit his particular needs. His natural pronunciation may also differ from "received" pronunciation in other respects, and particularly by the use of a different distribution of known sounds, as when a Londoner makes the last syllable of *opposite* rhyme with *might,* or when a native of Lancashire gives to the *u* in *butcher* the same value as it has in *cut.* Here phonetic transcriptions are useful for showing the difference of sound.

Phonemes.—When the sounds existing in a given language have been analysed, it is always found that some of them may be regarded as variants of others, which they replace in certain well-defined conditions. A family consisting of one distinctive sound of the language together with the variants which represent it in particular sound-combinations is called a "phoneme." The nature of a phoneme is best shown by examples. The three k's in *keep, cool, cot* are different sounds, but for practical purposes they may be treated as a single entity; they are said to belong to the same phoneme. The precise k-sound used in any particular case is determined by the nature of the neighbouring sounds, and the different varieties are not used for the purpose of distinguishing English words. Similarly the three t-sounds in *eight, eighth, train* belong to one phoneme, because the variants in *eighth* (phonetically eɪtθ), *train,* are dependent upon the neighbouring sounds θ, r. The French sounds l and l̥ (voiceless l) are members of the same phoneme. l̥ is used in French only in final position when a consonant precedes, as when the word *boucle* occurs at the end of a sentence; ordinary voiced l does not occur in this position, and consequently a Frenchman naturally regards the two very dissimilar sounds l and l̥ as a single entity.

It often happens that sounds which belong to one phoneme in one language constitute separate phonemes in another language; they are consequently used for the purpose of distinguishing words in the second language though not in the first. Thus l and l̥ are separate phonemes in Welsh, Burmese and Zulu, though they constitute only one phoneme in French (l̥ is transcribed ɬ when it is a separate phoneme). Again h and ç (the German *ich*-sound) are separate phonemes in German, but ç is a member of the h-phoneme in Japanese (the sound used when i follows). The French sounds of *è* and *é* are separate phonemes in French and are used for distinguishing words in that language; but similar sounds occur in Russian and in Zulu as members of one phoneme, their use being determined in Russian by the nature of the adjacent consonants and in Zulu by a principle of vowel-harmony.

Phonemes are families of sounds occurring in a language as pronounced by a single individual. They must be distinguished from diaphones (*see* below) which contain sounds used by two or more different speakers of a language.

The simplest system of phonetic transcription of a language is that which provides one symbol for each phoneme of that language. Such a system is known as "broad" transcription. It is unambiguous to the native and to anyone who knows the rules governing the use of the subsidiary members of the phonemes. More detailed transcriptions, providing symbols for subsidiary members of phonemes, are called "narrow" transcriptions. They are useful in comparative work, dialectology, etc.

Diaphones.—Speakers of the same language often do not all use exactly the same sounds. Thus the vowel element of the word *day* is pronounced in several different ways according to the locality and to the social position of the speaker (phonetically deː, deɪ, dɛɪ, dɛe, dæɪ, etc.). In such cases it is convenient to have a term to denote the family of sounds consisting of a sound of a language as pronounced by an "average" speaker together with other sounds which are used in place of it by other speakers. Thus the various vowel sounds used in the word *day* by different speakers of English are said to constitute one diaphone in the English language.

Phonetic Symbols.—In nearly every language the number of phonemes is greater than the number of letters in the Roman alphabet. It is therefore impossible to represent most languages unambiguously by means of the ordinary Roman letters only. So any romanic phonetic system, whether designed as a current orthography or as a transcription for the use of language learners, must contain new letters to supplement those of the present Roman alphabet. It can be shown that, on psychological, typographical and pedagogical grounds, specially designed letters are better than ordinary Roman letters with diacritical marks attached. In the designing of new letters several factors have to be taken into consideration, the chief of which is that the printed forms of the letters should harmonize as well as possible with the ordinary Roman characters, so that the general appearance of the printed page may be satisfactory. It must also be possible to write the new letters with ease. It is further desirable that the letters should have italic forms which do not differ from the Roman forms in any essential part of their outline. To ensure legibility it is necessary that each letter should be as different as possible from every other letter. For typographical reasons the letters should, as far as possible, be designed so as to avoid the necessity of kerned types. Kerns at the top or bottom of the type are entirely inadmissible. Kerns at the side are undesirable and must be resorted to as sparingly as possible; but it does not seem possible in a comprehensive alphabet to avoid them altogether. Lastly, it is a great advantage that the phonetic alphabet as a whole should be international, that is to say that each letter should always be used with the same or approximately the same value.

Of the phonetic alphabets hitherto invented only one, that of the International Phonetic Association, complies satisfactorily with the above-mentioned requirements. The next best is the Swedish dialect alphabet (which, in spite of its name, is really international).

Manner of Using a Phonetic Alphabet.—In constructing phonetic orthographies, or in making phonetic transcripts for

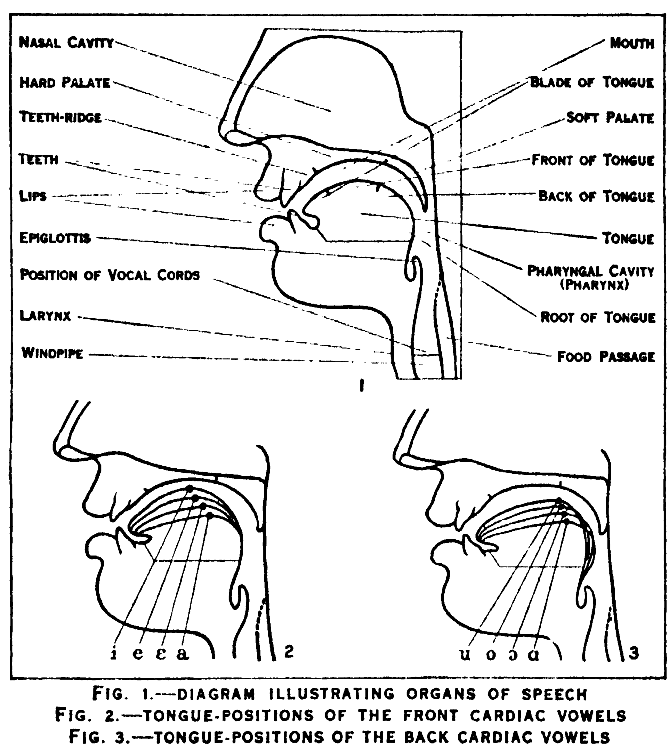


FIG. 1.—DIAGRAM ILLUSTRATING ORGANS OF SPEECH
FIG. 2.—TONGUE-POSITIONS OF THE FRONT CARDIAC VOWELS
FIG. 3.—TONGUE-POSITIONS OF THE BACK CARDIAC VOWELS

language students, attention must be given not only to the design of any special letters that may be required, but also to the manner of using the alphabet. This will depend (1) on the precise purpose for which the alphabet is required, and (2) on the structure of the particular language or languages dealt with. Thus if the writer's purpose is to make a comparative study of related languages he may be obliged to mark distinctions which it would be unnecessary to mark in a transcript of one language for the use of those who wish to learn to speak it.

THE INTERNATIONAL PHONETIC ALPHABET.

CONSONANTS	Bi-labial	Labio-dental	Dental and Alveolar	Retroflex	Palato-alveolar	Alveolo-palatal	Palatal	Velar	Uvular	Pharyngal	Glottal
Plosive	p b		t d	ʈ ɖ			c ɟ	k g	q ɢ		ʔ
Nasal	m	ɱ	n	ɳ			ɲ	ŋ	ɴ		
Lateral Fricative			ɬ ɮ								
Lateral Non-fricative			l	ɭ			ʎ				
Rolled			r						ʀ		
Flapped			ɾ	ɽ					ʀ		
Fricative	ɸ β	f v	θ ð s z ɹ	ʂ ʐ	ʃ ʒ	ɕ ʑ	ç j	x ɣ	χ ʁ	ħ ʕ	h ɦ
Frictionless Continuants and Semi-vowels	w ɥ	ʋ	ɹ				j (ɥ)	(w)	ʁ		

VOWELS	Bi-labial	Front	Central	Back
Close	(y ʉ u)	i y	ɨ ʉ	ɯ u
	(ʏ ʊ)	ɪ ʏ		ʊ
Half-close	(ø o)	e ø		ɤ o
			ɵ	
Half-open	(œ ɔ)	ɛ œ	ɜ	ʌ ɔ
			æ ɐ	
Open	(ɒ)		a	ɑ ɒ

(Secondary articulations are shown by symbols in brackets.)

OTHER SOUNDS.—Palatalized consonants: ƫ, ȡ, etc. Velarized or pharyngalized consonants: ɫ, ᵭ, ᵴ, etc. Ejective consonants (plosives with simultaneous glottal stop): p', t', etc. Implosive voiced consonants: ɓ, ɗ, etc. ɼ fricative trill. σ, ϱ (labialized θ, ð, or s, z). ʅ, ʓ (labialized ʃ, ʒ). ʇ, ʗ, ʖ (clicks, Zulu *c*, *q*, *x*). ɺ (a sound between r and l). ʍ (voiceless w). ɵ (a vowel between ø and o).

Affricates are normally represented by groups of two consonants (ts, tʃ, dʒ, etc.), but, when necessary, ligatures are used (ʦ, ʧ, ʤ, etc.), or the marks ⁀ or ‿ (t͡s or t‿s, etc.). c, ɟ may occasionally be used in place of tʃ, dʒ. Aspirated plosives: ph, th, etc.

LENGTH, STRESS, PITCH.— ː (full length). ˑ (half length). ˈ (stress, placed at beginning of the stressed syllable). ˌ (secondary stress). ¯ (high level pitch); ˍ (low level); ˊ (high rising); ˏ (low rising); ˋ (high falling); ˎ (low falling); ˆ (rise-fall); ˇ (fall-rise). See *Ecriture Phonétique Internationale*, p. 9.

MODIFIERS.— ˜ nasality. ̥ breath (l̥ = breathed l). ̬ voice (s̬ = z). ʻ slight aspiration following p, t, etc. ̣ specially close vowel (ẹ = a very close e). ̨ specially open vowel (ę = a rather open e). ̫ labialization (n̫ = labialized n). ̪ dental articulation (t̪ = dental t). ˙ palatalization (ż = ʒ). ˔ tongue slightly raised. ˕ tongue slightly lowered. ˒ lips more rounded. ˓ lips more spread. ̩ (e.g. n̩) syllabic consonant. ̆ consonantal vowel. ʃˢ variety of ʃ resembling s, etc.

Classification of Speech-sounds.—The above table of the International Phonetic symbols taken in conjunction with the chart of the organs of speech (fig. 1) shows the chief principles of sound classification. The meanings of most of the technical terms describing the various classes of sounds are self-evident. Attention may, however, be called to the following, which require some explanation. The "back" of the tongue is the part which lies normally opposite the soft palate (velum); the "front" is the part which lies normally opposite the "hard" palate; the "blade" is the part which lies normally opposite the teeth-ridge (upper gum, alveolars). "Palatal" consonants are those formed by the "front" of the tongue against the hard palate, such as the English sound of *y* or the German *ch* in *ich*. "Retroflex" consonants are those made by the tip of the tongue against the hard palate such as the Hindi sounds of ट ड.

Classification of Vowels.—Vowels are classified (1) according to the position of the tongue, and (2) according to the position of the lips. In forming a vowel the opening between the lips and the distance of the tongue from the palate must be sufficient to ensure that there is no audible friction when voice is emitted. The lips may be spread (as for the English *ee*-sound) or they may have "close" rounding (as in the sound of *u* in *rule*) or "open" rounding (as in the vowel in *long*). The classification of vowels according to tongue positions and the terminology employed in describing vowels is shown in figs. 2, 3 and 4. The relative tongue-positions of vowels may be indicated by dots placed on the vowel figure (fig. 4).

Cardinal Vowels.—In order to give an intelligible description of the vowels of any language, it has been found necessary to

marked by the large black dots in fig. 4. The eight primary cardinal vowels are represented by the letters i, e, ɛ, a, ɑ, ɔ, o, u; these are numbered 1 to 8 respectively. Eight secondary cardinal vowels are represented by y, ø, œ, –, ɒ, ʌ, ɤ, ɯ (numbered 9 to 16 respectively). (No letter has been adopted for secondary cardinal vowel No. 12, as it has not been found to exist as a separate phoneme in any language.) They have the same tongue-positions as the primary cardinal vowels, but different lip-positions. Nos. 9 to 13 have lip-rounding, and Nos. 14, 15, 16 have lip-spreading. The tongue-positions of any vowel may be represented by a dot at the appropriate place on the cardinal vowel chart. This marking, together with a description of the lip-position, shows the language learner exactly how the vowel is formed, and gives him a good idea of what it sounds like. Thus a foreign learner who has never heard English can learn to make the vowel of *cat* when he knows that it is half way between cardinal vowels 3 and 4 (ɛ and a). An Englishman learning Italian without a teacher can get a good idea of what the Italian vowels sound like from a diagram (fig. 5) which shows the relationship of the Italian vowels to the cardinal vowels.

In transcribing particular languages, the cardinal vowel letters are used to represent sounds in the vicinity of the cardinal vowel sounds. The letters, in fact, serve to represent vowels lying within certain areas on the vowel figure as shown in fig. 2. In the comparatively unusual cases when two vowel-sounds within the same cardinal area are used for the purpose of distinguishing words additional vowel-letters have to be introduced. Such are ɪ (used for the English vowel in *sit*), ʊ (used for the English vowel in *put*), ʏ (used for the German vowel in *Glück*). æ is

corner of the a-area, though there is no objection to using a for it except in comparative work. Symbols are also required for "central" vowels. The most important is ə which represents the "neutral" or "intermediate" sound of *a* in *along*. Others are ɨ, ʉ, which represent unrounded and rounded vowels with tongue-positions intermediate between those of i and u; ɨ is the Russian ы and ʉ is heard in the Norwegian *hus* and in a frequent Scottish pronunciation of *book*. The vowel in the London pronunciation of *bird* is represented by ɜ or by ə with a length mark (əː).

Intonation.—An important branch of phonetics is that which deals with intonation or the rise and fall in the musical pitch of the voice. In the languages called "tone languages" (*e.g.*, Chinese and most Sudanic and Bantu languages) intonation is used to distinguish one word from another. Thus in Cantonese the syllable *fan* said with a high falling tone means "divide"; said with five other tones it means "powder," "sleep," "burn," "courageous" and "duty" respectively. In the Sechuana language of South Africa *metse* said with a mid level tone on each syllable means "villages," but with a mid-level tone on the first syllable and a high level tone on the second it means "water."

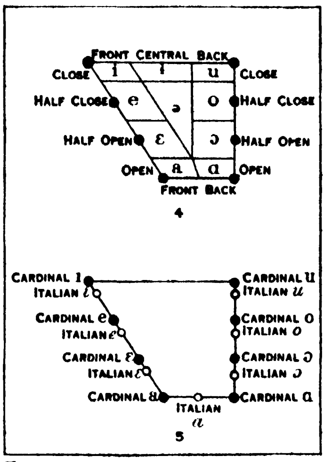

FIG. 4.—THE VOWEL AREAS SERVED BY THE MOST IMPORTANT VOWEL-LETTERS

FIG. 5.—THE ITALIAN VOWELS COMPARED WITH THE CARDINAL VOWELS

Such tones are best indicated in phonetic transcription by accent marks which by their shapes and positions give a certain graphic representation of the musical values of the tones, thus:—high level tone ā, low level tone a̠ high falling tone à, low falling tone a̖, high rising tone á, low rising tone a̗, fall-rise a̭, rise-fall â, etc. It is sometimes convenient to place the tone-marks before the syllable.

In languages which are not "tone languages" intonation affects the meaning of whole sentences, but it is not an integral part of any word. Intonation then gives "expression" to sentences; it conveys shades of meaning which cannot conveniently be expressed by other means. Thus in English the two meanings of *I beg your pardon* ("I am sorry" and "What did you say?") are distinguished by intonation. It is not practicable to mark this kind of intonation in orthography, though slight indications of it may be given by punctuation marks, the use of italics, etc.

PHONOGRAPH, an instrument for reproducing sound by transmitting to the air the mechanical vibrations of a stylus in contact with a sinuous groove in a moving record. Less specifically the term designates any instrument for recording and reproducing speech. The first audible reproduction of recorded sound was accomplished by Thomas A. Edison in 1877.

The history of most of the technical arts shows that their development takes place irregularly. The introduction of fundamentally new ideas introduces periods of very rapid advance. These periods are followed by intervals during which the development appears much slower and is concerned mainly with the refinement of methods and the adaptation of the new results to commercial processes. The phonographic art is no exception.

Since the last big advance which became commercially prominent in 1925, the improvements have been largely an adaptation of the tools provided, to the production of artistic and commercially valuable results. The tools which were made available by this last advance are completely described under the heading GRAMOPHONE. The major portion of the improvement introduced has dealt with the co-ordination of the results obtainable with the new equipment and the production of a proper artistic effect. As might be expected, this has dealt mainly with the study of the proper acoustic conditions in the space in which the sound is produced.

The early recording by the new process was done largely in small rooms in which the acoustics were well controlled. It was soon found that the acoustic properties of small rooms were totally unsuited to the proper artistic effect when dealing with those types of music which are usually produced in large auditoriums or theatres. A large amount of experimenting was, therefore, done, which showed definitely that the best way to record symphony orchestras, choruses, opera selections, etc., was to place the artists in a small theatre or auditorium, and to arrange them in much the way that they would be arranged were an audience present.

The early experiments indicated two major difficulties with this type of arrangement. First, there appeared to be excessive reverberation; and, secondly, it was difficult to find a situation for the microphone or pick-up device at which interference was

not present in certain frequency regions. (That is, at certain parts of the musical scale.)

It was found by experiment that the time of reverberation, as in small studios, should be approximately ·7 to ·8 of that required for audience listening. Also, it was found that the portion of the space in which the sound is produced should have surfaces of more reflecting ability than the average indicated for the auditorium, while the space in which the microphone or pick-up device is situated should be as dead or well damped as possible.

In the field of phonograph reproduction, there have been no major developments within the last few years. The trend of the improvements introduced has been towards the use of electric methods rather than mechanical. The wide range of both frequency and loudness, which can be obtained by the use of electric methods and the simplicity with which the loudness can be controlled, is probably mainly responsible for this trend. While for small, low-priced instruments, it is still possible to obtain more faithful reproduction with the mechanical machines, the improvements in the electric methods of reproduction have caused this method to take precedence in the higher priced field.

PHONOLITE, in petrology, a group of alkaline lavas containing much nepheline and sanidine felspar (Gr. *φωνή*, sound, and *λίθος*, stone). The term "clinkstone" was formerly given by geologists to many fine-grained compact lavas, which split into thin tough plates, and gave out a ringing sound when struck with the hammer. Some of these were phonolites in the modern sense, but as the name clinkstone was used for a large variety of rocks, many of which have no close affinities with one another, it has been discarded and "phonolite" substituted. The group includes rocks which are rich in alkalis with only a moderate percentage of silica; hence they contain no free quartz but much alkali-felspar (sanidine and anorthoclase) and nepheline. Large plates of sanidine are often visible in the rocks; the nepheline is usually not obvious to the unaided eye. Most phonolites show fluxion structure, both in the orientation of their phenocrysts and in the smaller crystals which make up the ground-mass; and this determines to a large extent the platy jointing. Although vitreous and pumiceous forms are known they are rare, and in the great majority of cases these rocks are finely crystalline with a dull or shimmering lustre in the ground-mass.

Dominant Minerals.—These are sanidine, nepheline, pyroxene, amphibole, various felspathoids and iron oxides. The sanidine is usually in two generations, the first consisting of large crystals of flattened and tabular shape, while the second is represented by small rectangular prisms arranged in parallel streams in the ground-mass; these felspars are nearly always simply twinned on the Carlsbad plan. They contain often as much soda as potash. The nepheline takes the form of hexagonal prisms with flat ends, and may be completely replaced by fibrous zeolites, so that it can only be recognized by the outlines of its pseudomorphs. In some phonolites it is exceedingly abundant in the ground-mass, and these rocks form transitions to the nephelinites (nephelinitoid phonolites); in others it is scarce and the rocks resemble trachytes containing a little nepheline (trachytoid phonolites). The felspathoid minerals, sodalite, haüyne and nosean, which crystallize in isometric dodecahedra, are very frequent components of the phonolites; their crystals are often corroded. Small rounded enclosures of glass are often numerous in them. The pyroxenes may be pale green diopside, dark green aegirine-augite, or blackish green aegirine (soda iron pyroxene), and in many cases are complex, the outer portions being aegirine while the centre is diopside. Fine needles of aegirine are often found in the ground-mass.

The chemical analyses of phonolites given herewith show that they are very rich in alkalis and alumina with only a moderate amount of silica, while lime, magnesia and iron oxides are present only in small quantity. They have a close resemblance in these respects to the nepheline-syenites of which they provide the effusive types. Most of these rocks are of Tertiary or Recent age, but in Scotland Carboniferous phonolites occur in several localities, *e.g.*, Traprain in Haddingtonshire, in the Eildon Hills and in Renfrewshire; in Brazil phonolites belonging to the same epoch are also known and there are several districts in Europe where Tertiary or Recent phonolites occur in considerable numbers, as in Auvergne (Mont Dore), the Eifel and Bohemia. The Wolf Rock, off the S. of Cornwall and the site of a well-known lighthouse, is the only mass of phonolite in England; it is supposed to be the remains of a Tertiary lava or intrusion. In the United States phonolites occur in Colorado (at Cripple Creek) and in the Black Hills of South Dakota.

Leucite occurs in place of nepheline in a small group of phonolites (the leucite-phonolites), known principally from Rocca Monfina and other places near Naples. When sanidine, nepheline and leucite all occur together in a volcanic rock it is classed among the leucitophyres (*see* Petrology).

PHORMION, Athenian admiral in the 5th century B.C., was the son of Asopius, of the deme Paeania. He first appears in 440 B.C. when he was sent with reinforcements to the Athenian troops before Samos. In 432 he took out reinforcements to the force blockading Potidaea, took over the command from Callias, and completed the circumvallation of the city. He seems to have stayed in the north-east, as in 431 he was co-operating with Perdiccas against the Chalcidians. In 430 he was sent with 30 ships to help the Acarnanians against the Ambraciots. That winter there followed the operations on which his fame is based. He was given 20 ships and stationed at Naupactus, to effect a blockade of Corinth from that side. In the summer of 429 a superior Peloponnesian fleet arrived, and was decisively beaten by Phormion. In a second engagement he was forced to retreat, but turned and again routed his pursuers. He was probably dead by 428.

PHORMIUM or **NEW ZEALAND FLAX** (also called "New Zealand hemp"), a fibre obtained from the leaves of *Phormium tenax* (family Liliaceae), a native of New Zealand, the Chatham islands and Norfolk island. This plant was discovered by Sir Joseph Banks and Dr. Solander, who accompanied Captain Cook on his first voyage of discovery. It grows luxuriantly in the south of Ireland, where it was introduced in 1798, and also flourishes on the west coast of Scotland, and is generally cultivated as an ornamental garden plant in the warmer parts of Europe and North America. It has been introduced for economic purposes into the Azores and California. The name *Phormium* is from Gr. *φορμός*, a basket, in allusion to one of the uses made of its leaves by the New Zealanders. It has a fleshy rootstock, creeping beneath the surface of the soil and sending up luxuriant tufts of narrow, sword-shaped leaves, from 4 to 8 ft. long and from 2 to 4 in. in diameter The leaves are vertical, and arranged in two rows as in the garden flag; they are very thick, stiff and leathery, dark green above, paler below, with the margin and nerve reddish-orange. From the centre of the tuft ultimately arises a tall flower-bearing stem, 5 to 15 ft. high, bearing on its numerous branches a very large number of lurid red or yellow, somewhat tubular

flowers, recalling those of an aloe, and from 1 to 2 in. long. After flowering the plant dies down, but increases by new lateral growths from the rootstock. The plant will grow in almost any soil, but best on light rich soil, by the side of rivers and brooks, where sheltered from the wind.

Phormium is a cream-coloured fibre with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax. It is, however, principally, a cordage fibre, and in tensile strength it is second only to manila hemp; but it does not bear so well the alternations of wet and dry to which ship-ropes are subject.

PHORONIS. *Phoronis* is one of those limbless creatures popularly termed "worms." It is, however, so peculiar in its structure that it is given a class to itself, Phoronidea There are a good many species found all over the world, but they are so alike that they are placed in a single genus *Phoronis,* although they vary from ½ in. to 6 in. in length. *Phoronis* is marine and lives in a leathery tube from which the fore-part of the body can be protruded The front part carries a peculiar platform or "lophophore," crowned with beautiful upright tentacles covered with cilia which are in perpetual motion. In *P. hippocrepia* the lophophore is shaped like a horse-shoe and the tentacles are arranged along its edge, those on the concavity of the shoe being somewhat the shorter. All species have lophophores more or less of this shape but the tips of the shoe are in some much more prolonged than in others and even inrolled. The cilia produce a current which sweeps small organisms into the mouth, situated between the outer and inner row of tentacles It is elongated and slit-like and provided with a covering lip, the epistome, which projects from the concave side of the lophophore Below the lophophore, on the side of the concavity of the horseshoe, the anus projects as a little papilla. At the sides of the anus two smaller papillae carry the openings of a pair of ciliated tubes which connect the body-cavity with the exterior. These tubes (*coelomiducts*) serve to get rid of the excreta in the body-cavity fluid and to let out the germ-cells when these are ripe

Since the mouth and anus are close together and the animal has a long worm-like body, it is obvious that the alimentary tube will be U-shaped. The long gullet leads into a globular stomach lying at the lower end of the body, from which the long, slender, ascending intestine leads to the anus. The first part of the intestine where it leaves the stomach is swollen, lined by ciliated epithelium and devoid of glands. The alimentary tube is enswathed by a true secondary body-cavity or coelom, which is lined by an epithelium the outer layer of which is pressed against the body-wall whilst the inner layer lies against the gut cells This cavity is divided into two by a horizontal platform just behind the mouth. The front portion communicates with the cavities of the tentacles and of the epistome. This is the lophophoral coelom: the hinder portion, in which the gullet and intestine lie, and into which the coelomiducts open, is the trunk-coelom and is traversed by a median septum or mesentery which ties the outer side of the oesophagus to the body wall: in addition, the oesophagus is anchored by two lateral mesenteries. These mesenteries, however, cease before the stomach is reached. The genital cells appear as thickenings of the inner wall of the coelom and both male and female are produced by the same individual in separate swellings, projecting from the wall of the stomach. The trunk coelom is thus divided into three chambers, a right and left lateral on the convex side of the lophophore and a large rectal chamber on the concave side. In this latter lies the intestine, which is tied to the body wall by its own independent mesentery and is also fused by its side to one of the lateral mesenteries

Each "coelomiduct" opens into the body-cavity by two funnel-shaped openings lined by cilia, a short one communicating with the lateral chamber and a long slit-like one opening into the rectal chamber.

The nervous system is simple, consisting merely of an interlacing mass of extremely fine fibrils and small nerve-cells which thickens to form a horizontal band passing around the lophophore and giving off a special branch to each tentacle. There is also a thickening in the skin of the epistome.

The life of *Phoronis* consists merely in expanding the front of the body, erecting the tentacles and working the cilia vigorously; the mouth being opened wide to catch whatever fortune brings. On the approach of danger the whole body is withdrawn within the tube This is effected by bands of longitudinal muscles in the body-wall—the expansion being brought about by circular muscles, which by compressing the body force fluid into the lophophore and engorge it

The interest of *Phoronis* lies in its strong resemblance to certain *Polyzoa* (*q.v.*). Lankester went so far as to call Phoronis the only solitary polyzoon. But *Phoronis* possesses, distinct altogether from the body-cavity, a well-developed blood-system, containing a colourless serum in which float red blood corpuscles. No such organ is found in any polyzoon. This blood-system consists of an "artery" running on the anal side of the gullet to the level of the lophophore where it gives off right and left a vessel to each arm of the lophophore. From these a single vessel goes to each tentacle This vessel at the base of the tentacle sends a fork to an outer or recipient vessel, which runs along the convex side of the lophophore on each side. The right and left recipient vessels pass downwards, pierce the lophophoral platform and unite on the convex side of the oesophagus to form a single "vein" which below the stomach opens into the artery

The reproduction raises other questions. The eggs, after being shed, stick to the tentacles and are there fertilized by sperms from another individual. They complete the first stages of their development within the egg-membrane, from which they hatch out as peculiar free-swimming larvae known as *Actinotrocha* This larva is provided with a ciliated forehead in which a large ganglion is embedded There is an oblique wreath of ciliated tentacles behind the mouth by which it swims. There is a belt of cilia round the hind end of the body in front of the anus This larva after feeding for a time and growing greatly in size, develops an intucking of skin on its under-surface, to which a fold of the intestine becomes attached Suddenly (inside a quarter of an hour) this intucked area is everted, forming a finger-shaped process containing a loop of the intestine which gives rise to the body of the "worm" The ciliated forehead is cast off, as are also the ciliated tentacles, but new tentacles which give rise to the lophophore of the adult are regenerated from their stumps This larva with its extraordinary life-history has given rise to much speculation. We owe the clearing up of its real affinities to E S Goodrich and Shearer, who have shown that *Actinotrocha* is merely a modified trochophore, such as occurs in the life-history of the Gephyrea amongst the Annelida (*q v*). The typical trochophore has a broad preoral belt of *cilia,* the *prototroch,* and a slender postoral one, the *metatroch,* whilst a belt of cilia, the *telotroch,* encircles just in front of the anus.

(E. W. MacB.)

PHORORHACOS, a gigantic extinct Patagonian bird, allied to the Cranes and in some respects recalling the South American *Cariama* bird. About six species of the type genus have been discovered, the most complete being *P. inflatus,* with skull, mandible, pelvis, limbs and some of the vertebrae The skull of *P. longissimus* is about 2ft. long and 10in high; that of *P. inflatus* is 13in. long, and this creature is supposed to have stood only 3ft high at the middle of the back. The under jaw is slightly curved upwards. The strongly hooked upper beak is high, and laterally compressed. The vomer is inconspicuous. The quadrate has a double knob for articulation with the skull, and basipterygoid processes are absent. What little is known of the shoulder-girdle points to a flightless bird, and so do the short wing bones, although these are stout. The pelvis has an ischiadic foramen. The hind limbs are distinctly slender, the tibia of *P. inflatus* being between 15 and 16in. in length.

THE SKULL OF PHORORHACOS LONGISSIMUS, AN EXTINCT BIRD OF PREY

PHOSGENE or **CARBONYL CHLORIDE,** an extremely poisonous, heavy gas, came into prominence during the

World War (1914–18), being used either alone or in mixtures both for cloud-gas and shell-gas attacks. It has a nauseating, choking smell, and, even in very small doses has very bad after-effects on the heart and lungs. Phosgene owes its name to the fact that it can be formed by exposing carbon monoxide and chlorine to sunlight ($CO+Cl_2=COCl_2$), but it is now manufactured by passing the two gases over specially prepared charcoal catalyst (*see* CATALYSIS). Phosgene can be condensed to a liquid which boils at 8° C under ordinary pressure; it is stored either in steel cylinders under slight pressure or as a solution in toluene. It is very reactive chemically and is used in the dyestuff industry for the manufacture of intermediates. It also reacts rapidly with water to give carbon dioxide and hydrogen chloride (hydrochloric acid): $COCl_2+H_2O_2=CO_2+HCl$. (*See* also CARBON.)

PHOSGENITE, a rare mineral consisting of lead chlorocarbonate $(PbCl)_2CO_3$. The tetragonal crystals are prismatic or tabular in habit, and are bounded by smooth, bright faces; they are usually colourless and transparent, and have a brilliant adamantine lustre. Sometimes the crystals have a curious helical twist about the tetrad or principal axis. The hardness is 3 and the specific gravity 6·3. The mineral is rather sectile, and consequently was early known as "corneous lead." The fanciful name phosgenite is from phosgene, the old name of carbon oxychloride, because the mineral contains the elements carbon, oxygen and chlorine. At Cromford in Derbyshire it was long ago found in an old lead mine, being associated with anglesite and matlockite (Pb_2OCl_2) in cavities in decomposed galena; hence its synonym cromfordite.

PHOSPHATES, salts of phosphoric acid. Phosphoric oxide, P_2O_5 or P_4O_{10} (Tilden and Barnett, *v. inf.*), combines with water in three proportions to form $H_2O{\cdot}P_2O_5$ or HPO_3, metaphosphoric acid; $2H_2O{\cdot}P_2O_5$ or $H_4P_2O_7$, pyrophosphoric acid; and $3H_2O{\cdot}P_2O_5$ or H_3PO_4, orthophosphoric or ordinary phosphoric acid. These acids each give origin to several series of salts, those of ordinary phosphoric acid being the most important.

Orthophosphoric acid, H_3PO_4, a tribasic acid, is obtained by boiling a solution of the pentoxide in water; by oxidizing red phosphorus with nitric acid, or white phosphorus under the surface of water by bromine or iodine; and also by decomposing a mineral phosphate with sulphuric acid. It usually forms a thin syrup which on concentration in a vacuum over sulphuric acid deposits hard, transparent, rhombic prisms which melt at 41·7° C. After long heating the syrup is partially converted into pyrophosphoric and metaphosphoric acids, but on addition of water and boiling the ortho-acid is re-formed. It gives origin to three classes of salts: $M'H_2PO_4$ or $M''(H_2PO_4)_2$; M'_2HPO_4 or $M''HPO_4$; and M'_3PO_4, $M''_3(PO_4)_2$ or $M'''PO_4$, wherein M', M'', M''' denote a uni-, bi-, and tri-valent metal. These correspond to H_3PO_4 in which one, two or three atoms of hydrogen, respectively, have been replaced by a metal. The three principal groups differ remarkably in their behaviour towards indicators. Those of the first type are strongly acid, the second are neutral or faintly alkaline, whilst the third are strongly alkaline and are decomposed by carbon dioxide: $Na_3PO_4+CO_2+H_2O=NaHCO_3+Na_2HPO_4$. The salts of the types NaH_2PO_4 and $CaH_4P_2O_8$ may be obtained in crystal form, but those of the heavy metals are only stable when in solution. All soluble orthophosphates give with silver nitrate a characteristic yellow precipitate of silver phosphate, Ag_3PO_4, soluble in ammonia and in nitric acid. Since the reaction with the acid salts is attended by liberation of nitric acid: $NaH_2PO_4+3AgNO_3=Ag_3PO_4+NaNO_3+2HNO_3$, $Na_2HPO_4+3AgNO_3=Ag_3PO_4+2NaNO_3+HNO_3$, it is necessary to neutralize the nitric acid if the complete precipitation of the phosphoric acid be desired. The three series also differ when heated: the trimetallic salts containing fixed bases are unaltered, whilst the mono- and di-metallic salts yield meta- and pyro-phosphates respectively. Other common precipitants of phosphoric acid or its salts in solution are: ammonium molybdate in nitric acid, which gives on heating a canary-yellow precipitate of ammonium phosphomolybdate, $12[MoO_3]\ (NH_4)_3PO_4$, insoluble in acids but readily soluble in ammonia; magnesium chloride, ammonium chloride and ammonia, which give on standing in a warm place a white crystalline precipitate of magnesium ammonium phosphate, $Mg(NH_4)PO_4{\cdot}6H_2O$, which is soluble in acids but highly insoluble in ammonia solutions, and on heating to redness gives magnesium pyrophosphate, $Mg_2P_2O_7$.

Of the organic phosphates, triphenyl phosphate $(C_6H_5)_3PO_4$, is important, acting as a filler or "dope," and as a substitute for camphor. It is a colourless solid of m.p. 53° C and b.p. 245° C.

Pyrophosphoric acid, $H_4P_2O_7$, is a tetrabasic acid which may be regarded as derived by eliminating a molecule of water between two molecules of ordinary phosphoric acid; its constitution may therefore be written $(HO)_2OP{\cdot}O{\cdot}PO(OH)_2$. It may be obtained as a glassy mass, indistinguishable from metaphosphoric acid, by heating phosphoric acid to 215°. When boiled with water it forms the ortho-acid, and when heated to redness the meta-acid. After neutralization, it gives a white precipitate with silver nitrate. Being a tetrabasic acid it can form four classes of salts; for example, the four sodium salts $Na_4P_2O_7$, $Na_3HP_2O_7$, $Na_2H_2P_2O_7$, $NaH_3P_2O_7$ are known. The most important is the normal salt, $Na_4P_2O_7$, which is readily obtained by heating disodium orthophosphate, Na_2HPO_4. It forms monoclinic prisms (with $10H_2O$) which are permanent in air. All soluble pyrophosphates when boiled with water are converted into orthophosphates.

Metaphosphoric acid, HPO_3, or more correctly $H_2P_2O_6$ as determined by vapour density (Tilden and Barnett), is a monobasic acid which may be regarded as derived from orthophosphoric acid by the abstraction of one molecule of water, thus $H_3PO_4-H_2O=HPO_3$; its constitution is therefore $(HO)PO_2$. The acid is formed by dissolving phosphorus pentoxide in cold water, or by strongly heating orthophosphoric acid. It forms a colourless vitreous mass, hence its name "glacial phosphoric acid." It is readily soluble in water, the solution being gradually transformed into the ortho-acid, a reaction which proceeds much more rapidly on boiling. Although the acid is monobasic, salts of polymeric forms exist of the types $(MPO_3)_n$, where n may be 1, 2, 3, 4 or 6. They may be obtained by heating a monometallic orthophosphate of a fixed base, or a dimetallic orthophosphate of one fixed and one volatile base, *e.g.*, microcosmic salt: $MH_2PO_4=MPO_3+H_2O$; $(NH_4)NaHPO_4=NaPO_3+NH_3+H_2O$. The salts are usually non-crystalline and fusible. Their solutions on boiling yield orthophosphates, whilst those of heavy metals give a trimetallic orthophosphate and orthophosphoric acid: $3AgPO_3+3H_2O=Ag_3PO_4+2H_3PO_4$. Metaphosphoric acid can be distinguished from the other two acids by its power of coagulating albumen, and by not being precipitated by magnesium and ammonium chlorides in the presence of ammonia. For perphosphoric acids, *see* PHOSPHORUS.

PHOSPHORESCENCE. Physicists apply the word phosphorescence to the emission of light at low temperatures by certain substances (chiefly sulphides), after previous exposure to light or radiation of other kinds. However, common usage has made it applicable to the glow of phosphorus, or of the sea, or of dead fish or meat, or of wood, the "fox-fire" of forests. Phosphorescence of the sea or of flesh, wood, etc., is due to living organisms of various kinds and should more properly be called bioluminescence. Such light is the result of a slow oxidation of material manufactured by the organism.

At least 40 different orders of animals contain luminous species, and also two groups of plants, the bacteria, responsible for the luminescence of flesh, and the fungi, responsible for the luminescence of wood. Either the fine strands of fungus mycelium, which penetrate the wood, or the fruiting body, the mushroom, or both, may be luminous.

The luminous bacteria are so small that individuals cannot be seen by their own light, whereas natural colonies are easily visible. They may be cultured on artificial media and form excellent material for the experimental study of bioluminescence. They are not pathogenic to man but are known to infect living animals, giving rise to a natural luminescent disease of sand-fleas, shrimps and possibly midges, which is eventually fatal. Luminous bacteria may also live symbiotically in definite organs of fish, notably *Photoblepharon* and *Anomalops* of the Banda islands. Some believe that the luminescence of all luminous animals, even the firefly, is due to symbiotic luminous bacteria, but this is far from

proven. The characteristic of the light of bacteria and fungi, which distinguishes them from all other luminous organisms, is its uniformity, shining night and day, independently of stimulation. Other animals light only when disturbed or stimulated.

Phosphorescence of the sea is largely due to Protozoa, of which the Radiolaria, Dinoflagellata and Cystoflagellata (including *Noctiluca*) are luminous. The latter two groups may develop in such enormous numbers that the sea is a pink or red by day and a vivid sheet of flame by night. Larger patches of light in the ocean are mainly due to coelenterates, jelly-fish, Siphonophora or Ctenophora (comb-jellies). The latter are often very abundant and show the interesting phenomenon of loss of luminescence in sunlight or on bright illumination by electric light. The luminescence again appears on stimulation after about one-half hour in the dark. The coelenterates contain more luminous species than any other group, the sea pens or pennatulids showing especially brilliant luminescence, which travels along nerves over the colony of polyps in the form of a wave.

Among the Crustacea, Copepoda and Ostracoda (Cypridina) contain many luminous forms while the schizopod and decapod shrimps possess members with true luminous organs or photophores, often consisting of lens, reflector and pigment screens, veritable lanterns on a microscopic scale, earlier mistaken for eyes.

Among the worms, many marine forms and some earthworms are luminous. Among the echinoderms, only the brittle-stars (Ophiuroids) possess luminous members.

Luminous molluscs are represented only by *Pholas dactylus* (a bivalve) and *Phyllirrhoë bucephala* (a nudibranch), together with the cephalopods, of which many members produce light. The cephalopods and deep-sea fish possess the most complex lantern-like luminous organs.

Some centipedes are luminous, as well as the spring-tails, larvae of the fly, *Bolitophila,* which live in New Zealand caves, and beetles (fire-fly, glow-worm and *Pyrophorus* of the West Indies). All stages, including the egg, of some fire-flies are luminous.

Balanoglossus and *Pyrosoma,* primitive chordates, are also luminous. The latter forms large colonies, floating near the surface of the sea, each individual possessing two luminous spots.

Finally, mention should be made of the fish, both elasmobranchs and teleosts, containing luminous members. The deep-sea forms are often bizarre in appearance and sometimes contain the luminous organ on the end of a long process dangled before the animal as a lure for prey.

The sponges, Alcyonaria, Bryozoa, mayflies, termites, spiders and Salpae contain reported luminous forms, whose light-production is, however, doubtful. The light of many phosphorescent animals is not produced by the animals themselves but by symbiotic micro-organisms.

In general, luminous organs or regions are glandular and the luminous material may be ejected (extracellular luminescence) as a slime or a secretion, which in the squid, *Heteroteuthis dispar,* surrounds the animal in the sea water as does the black ink of other squids. Or the luminous material may be consumed within the photogenic cells (intracellular luminescence) as in the fire-fly and organisms possessing photophores. There is always a mechanism for supplying the organ with abundant oxygen, a fact which indicates that the light-production is an oxidation.

Chemical Nature of Bioluminescence.—Knowledge of the chemical nature of bioluminescence has proceeded in four steps. (1) R. Boyle (1667) showed that fungi and bacteria required air (oxygen) for luminescence, becoming dark under an air pump and luminescing again when air was readmitted.

(2) Reamur (1733) and Spallanzani (1794) showed that water was necessary, that luminous cells could be dried and preserved, in some cases indefinitely, producing light whenever moistened. This fact proves also that bioluminescence is not a process involving definite structural peculiarities of the cell, as is the contraction of a muscle or the conduction of a nerve impulse, which will not occur after drying and moistening.

(3) Dubois, in 1887, found that the photogenic material could be separated into two constituents, luciferin and luciferase, due to marked difference in chemical behaviour. The latter is destroyed on boiling and behaves like an enzyme or catalyst; the former is heat-resisting and the oxidizable body. These substances can be treated like any other chemical compound, precipitated by certain reagents and redissolved in appropriate solvents. They have been partially purified but their chemical composition is still unknown. Their isolation and synthesis is a matter of time and material.

(4) Harvey (1918) showed that luciferin, after oxidation to oxyluciferin, could be reduced again, that the luminescent process was reversible and of the nature of an oxidative dehydrogenation. It seems most probable that many organisms reduce the oxyluciferin formed during luminescence and thus re-utilize the material again and again, a principle that may in time be adopted in industry as the basis of an efficient method of illumination.

Bioluminescence is often spoken of as "cold light." This does not mean that no heat is produced, but only that very little appears as compared with the ordinary methods of illumination, which depend on the incandescence of carbon particle in flames or of wires through which a current is passing. The rise of temperature in some luminous animals is less than 0·001° C. The light is no different, physically, from any other kind of light—it will affect a photographic plate, can induce chemical reactions, and can be polarized. There are no infra-red or ultra-violet radiations and no penetrating radiations are produced. Hence the luminous efficiency, *i.e.,* the percentage of the radiant energy which is visible, is very high, nearly 100%. This does not tell, however, what the radiant efficiency is, *i.e.,* the percentage of the energy (chemical) of the oxidation process which appears as radiant energy; nor does it tell the overall efficiency, *i.e.,* the energy (chemical) in the food of the animal which appears as visible radiant energy. This is the efficiency in which an illuminating engineer is interested, and studies on luminous bacteria have shown that the overall efficiency of these forms is at least slightly and probably considerably greater than that of a nitrogen-filled incandescent lamp, when calculated from the energy of the coal necessary to run the dynamo that supplies current to the lamp.

The Uses of Luminescence.—Regarding the use of luminescence to the animal, little can be said with certainty. In deep-sea forms, living in perpetual darkness, it would seem that the organs must be lanterns for seeing or recognition, or for attracting prey. Many luminous forms live in light places, and it has been suggested that the luminescence may be a warning to scare away predacious animals which might molest the luminous forms, or a lure to attract creatures upon which the luminous animal feeds. These suggestions remain to be proven, but we do know that in the fire-fly the light acts as a signal or attraction to bring the sexes together. On the other hand, who can suggest the use of light to a luminous bacterium, an organism $\frac{1}{25,000}$ in. in diameter with no nervous reactions of a higher form, or the use to a protozoan, living at the surface of the sea, blown hither and thither by the wind? One is forced to the conclusion that in their case the light is merely fortuitous, a chance phenomenon, accompanying some of the chemical changes in the organism.

It is well known that many substances produce light on slow oxidation (chemiluminescence) and the whole process of light-production by luminous organisms can be so perfectly imitated by such reactions in the laboratory that we may no longer consider it a mysterious or unusual phenomenon.

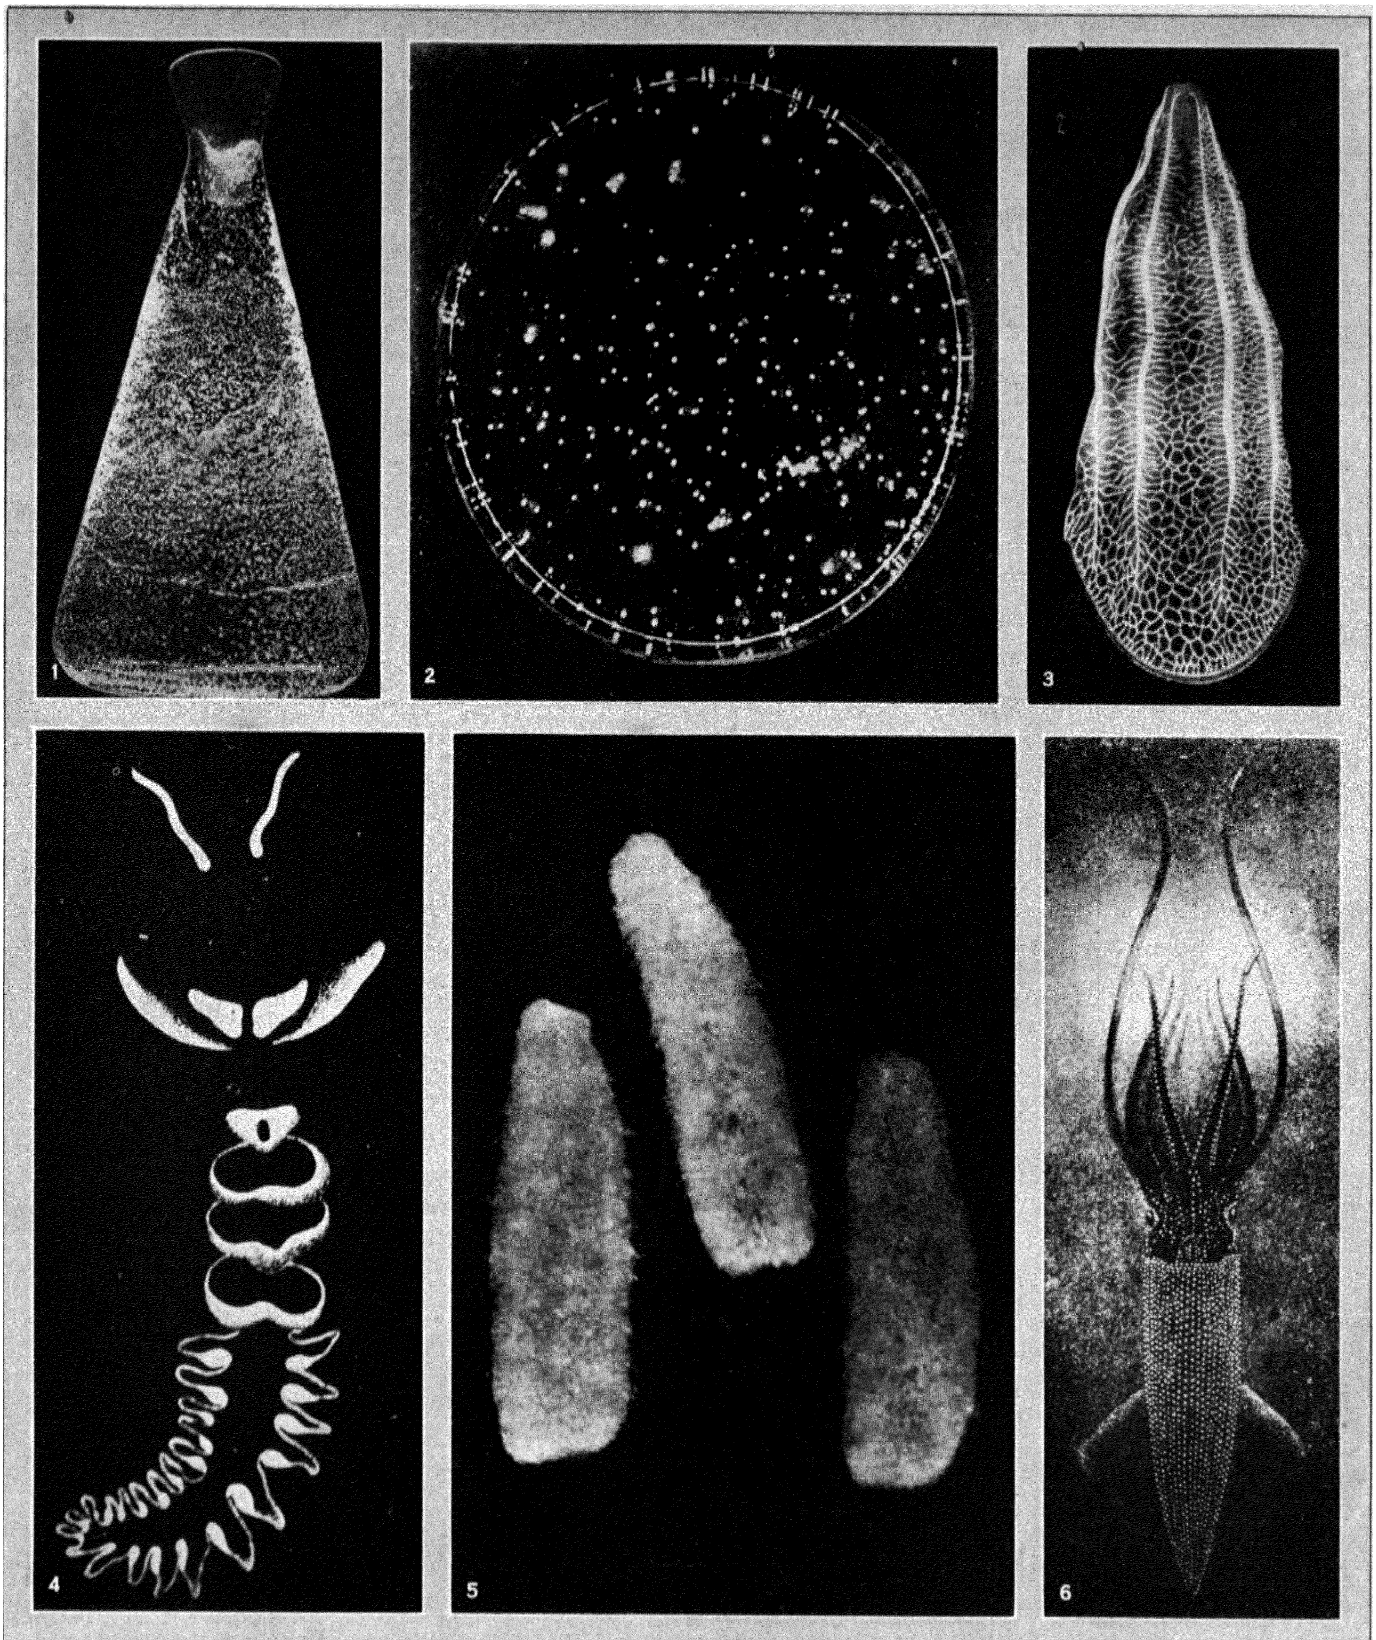
PHOSPHORITE, in mineralogy, the name given to impure massive apatite (*q.v.; see* also PHOSPHATES).

PHOSPHORUS, a non-metallic element, first known as *Phosphorus mirabilis* or *igneus.* (Symbol P, atomic number 15,



LUMINOUS ORGANISMS

1, 2. Colonies of luminous bacteria growing on culture media
3. "Comb" jellyfish or Ctenophore
4. A marine worm (*Chaetopterus*)
5. A sea-squirt (*Pyrosoma*)
6. A luminous squid (*Watasenia*)

atomic weight 30·98.) It is never found free, but is widely and abundantly distributed in combination as phosphates (*q.v.*). It is essential to animal and vegetable life, occurring in urine, blood and tissues, and, as calcium phosphate, forming 58% of bones. The element was first obtained in 1669 by Brand of Hamburg, who kept his process secret. In England, however, Kunckel (1678) and Boyle (1680) attempted its preparation and happened to use Brand's method—urine was evaporated to dryness and the residue distilled with sand. In 1775 Scheele prepared it from bones, and these still form one of the chief commercial sources of phosphorus. Degreased bones or mineral phosphates are treated with sufficient sulphuric acid to combine with all the calcium, this sulphate is filtered off, and the filtrate is mixed with charcoal, coke or sawdust, dried in a furnace, and then distilled from Stourbridge-clay retorts at a white heat. The vapours are led through malleable iron pipes into troughs containing water, where they condense. The reactions are:

$$Ca_3(PO_4)_2+3H_2SO_4=3CaSO_4+2H_3PO_4;\quad H_3PO_4=HPO_3+H_2O;$$
$$2HPO_3+6C=H_2+6CO+2P.$$

Modern Processes.—In more modern electrothermal processes, calcium phosphate is mixed with sand and carbon, and fed into a furnace heated by an alternating current. At the high temperature the silica of the sand displaces phosphoric oxide and forms calcium silicate, and the oxide is reduced by the carbon so that the phosphorus vapour and carbon monoxide pass over into a condenser. The silicate remains as a liquid slag and is run off periodically. Other processes seek to produce calcium carbide simultaneously with phosphorus by using only calcium phosphate and carbon, thus obtaining a more valuable by-product. In all cases the phosphorus is cast into sticks either under water or in water-cooled pipes.

Properties.—Perfectly pure phosphorus is a white, transparent waxy solid, its usual yellowish appearance being due to traces of the allotropic "red phosphorus," which is formed by exposure to light. At 25° to 30° C it is soft and flexible, but when cooled it becomes brittle and shows a crystalline fracture. Crystallization from carbon disulphide or sublimation yields large crystals of regular dodecahedra or octahedra, but these fire spontaneously unless protected from the air. It is also soluble in sulphur chloride, benzene, oil of turpentine, and liquefied ammonia or sulphur dioxide. It is a non-conductor of electricity, has density 1·836 at 0° C, melts at 44·3°, and boils at 287° giving a colourless vapour, the density of which corresponds to tetratomic molecules, P_4; above 1,500° C the vapour density indicates dissociation to P_2. The elevation of boiling point of solutions of phosphorus in carbon disulphide, and the depression of freezing point of solutions in benzene, both indicate P_4.

The element is highly inflammable, taking fire in air at 34°, burning with a bright white flame and forming dense white clouds of phosphoric oxide; H. B. Baker has shown, however, that in perfectly dry air or oxygen it can be distilled unchanged. (*See* DRYNESS, CHEMICAL.) When exposed to air which has not been excessively dried, a stick of phosphorus undergoes slow combustion, as shown by the phosphorescence visible in the dark. In pure oxygen, however, this phosphorescence is not exhibited unless the gas pressure is reduced or the temperature raised; similarly, in compressed air the phosphorescence ceases when a certain pressure is reached. Moreover, the presence of certain substances (*e.g.*, Cl, Br, I, NH_3, N_2O, NO_2, H_2S, SO_2, CH_4, C_2H_4) entirely inhibits the phosphorescence. During the process, oxygen is slightly ionized and traces of ozone are formed. Some of the phenomena accompanying phosphorescence have been ascribed to the oxidation of the trioxide. A very complete bibliography of investigations is given by W. E. Downey (*J. Chem. Soc.*, 1924, 125, p. 349), and H. J. Emeléus (*ibid.*, 1926, p. 1336; 1927, p. 788; 1928, p. 628) gives a further discussion of the inhibition and of the ultra-violet spectrum of the glow. Phosphorus combines directly with the halogens, sulphur and selenium, and most metals burn in its vapour forming phosphides. When very finely divided it decomposes water, giving hydrogen phosphide, and when boiled with water it gives hypophosphorous acid in addition; slow oxidation of wet phosphorus yields hypophosphoric acid.

PHYSICAL PROPERTIES

Allotropic Forms.—Many allotropic varieties of phosphorus have been described but it seems probable that the white and violet forms are the only definite allotropes (*see* ALLOTROPY), the others being "solid solutions" (*see* CHEMISTRY, PHYSICAL) of these two. The ordinary yellowish phosphorus is really white when pure, and probably owes its slight colour to a trace of the violet form. The so-called *red phosphorus* (used for matches) is produced by heating white phosphorus to about 230° C for 24 hours in an inert atmosphere, or to 300° C for a few minutes in closed vessels; a trace of iodine expedites the change. Commercially, the process is carried out in iron pots with air-tight lids which, however, have a long narrow tube open to the air; at first a little phosphorus burns, but this uses up all the oxygen, and the process thereafter continues in an inert atmosphere with no risk of explosion. The product is ground under water, freed from unchanged white phosphorus by boiling with caustic soda, washed and dried. The same form is also produced by submitting ordinary phosphorus to the silent electric discharge, to sunlight or to ultra-violet light. Red and white phosphorus differ greatly: the red does not inflame until heated above 350° C (hence its use in the match industry), is insoluble in all the solvents which dissolve the white, has a higher density (2·2), is stable to air and light, is much less chemically reactive (since its formation from white phosphorus is accompanied by liberation of much heat—3,700 cal. per 31 g.), and is non-poisonous.

Hittorf's "metallic" or *violet phosphorus* is formed by heating phosphorus with lead to redness in a sealed tube, and removing the lead by boiling with nitric acid or by electrolytic means. It is also obtained by heating white or red phosphorus for long periods at high temperatures, the proportion of violet phosphorus increasing with time and temperature. This fact, together with the circumstance that the density of red phosphorus continually increases with the duration and intensity of its heating, suggests that the red form is only an intermediate stage in the production of the violet. (*See* above.) This variety forms lustrous, heavy, nearly black, minute rhombohedra. A scarlet form was obtained by R. Schenk in 1905, and in 1921, P. W. Bridgman described a black graphitic variety which was obtained by heating ordinary phosphorus at 200° C under a pressure of 12,000 atmos., and which was incombustible, very dense, and conducted electricity. Bridgman obtained also another modification of white phosphorus, with a transition point at −76·9° C under atmospheric pressure. The relationships of these forms to white and violet phosphorus are indefinite. The various forms are probably polymerides, for the red phosphorus is at least as complex as P_8, whereas the white is P_4. Smits postulates two forms P_α and P_β as the basis of all varieties, and, as many of the conversions are very slow, the equilibria involved are probably complex.

Phosphine (phosphoretted hydrogen), PH_3, a gas formed in the putrefaction of organic matter containing phosphorus, was first obtained (Gengembre, 1789) by the action of potash on phosphorus; this was spontaneously inflammable, whereas Davy obtained a hydride which was not spontaneously inflammable by heating phosphorous acid. In 1835 Le Verrier showed that the two gases were essentially identical, and that the inflammability was due to traces of another hydride, P_2H_4. When caustic alkalis are boiled with phosphorus, the impure gas is obtained, and it also results from the action of water on calcium phosphide (unless this is very pure), but the pure PH_3 may be obtained by heating phosphonium iodide with caustic potash. It is a colourless, very poisonous gas, with an offensive odour like that of rotting fish; it can be liquefied at −86° C and solidified at −133°. It is only slightly soluble in water, burns with a luminous flame, fires spontaneously in air at about 100°, and combines violently with oxygen and the halogens. When passed over heated metals, it liberates hydrogen and forms the phosphide. It forms double compounds such as $PH_3.2BF_3$ and $2PH_3.SiCl_4$, gives phosphonium salts, PH_4X, with the halogen acids, and decomposes to its elements when heated out of contact with air. The hydride P_2H_4 can be condensed as a liquid if the impure gas (above) is passed through U-tubes in a freezing mixture. It boils at 57°–58° C, and above

this temperature it breaks down to P_4H_2, which also results when it is exposed to light or left in contact with hydrochloric acid. The hydride P_4H_2 is a solid obtained by the action of phosphorus trichloride on PH_3, or of water on phosphorus di-iodide.

PHOSPHONIC SALTS AND OXIDES

Phosphonium Salts.—The *chloride,* PH_4Cl, large transparent cubes can be obtained by direct combination of phosphine and hydrogen chloride at $-30°$ C but decomposes on rise of temperature. The *bromide* may be prepared similarly or by heating phosphorus with hydrobromic acid at 110° in sealed tubes; it is unstable in air and is decomposed by water. The *iodide* is readily obtained by mixing phosphorus and iodine in carbon disulphide in a retort, distilling off the solvent, adding the requisite quantity of water and subliming the iodide:

$$5I+9P+16H_2O=5PH_4I+4H_3PO_4.$$

Caustic alkali or more water decomposes it to phosphine and iodide or hydriodic acid.

Just as amines (*q.v.*) are derivatives of ammonia, so phosphine gives rise to primary, secondary and tertiary phosphines, and organic phosphonium bases correspond to phosphonium salts. The primary and secondary phosphines, RPH_2 and R_2PH, are formed when alkyl iodides are heated with phosphonium iodide and zinc oxide to 150° C, the reaction mixture is treated with water, whereby the primary phosphine is obtained, and the secondary phosphine is liberated from its hydriodide by caustic soda. The tertiary phosphines and quaternary phosphonium salts are formed by the same reaction at higher temperatures (180° C) and without the use of zinc oxide. The primary and secondary phosphines are colourless liquids (except methylphosphine which boils at $-14°$ C) of unpleasant odour; they react neutral but form salts with acids, and are often spontaneously inflammable; nitric acid oxidizes them to mono- and di-alkylphosphinic acids, respectively, $RPO(OH)_2$ and $R_2PO(OH)$. The tertiary phosphines tend to give derivatives of quinquevalent phosphorus, and therefore readily form addition compounds and are oxidized to phosphine oxides, R_3PO. The quaternary phosphonium salts resemble the corresponding nitrogen compounds, being stable towards aqueous alkalis but converted by digestion with moist silver oxide to the very strongly alkaline phosphonium hydroxide; on heating, they decompose to the phosphine oxide and a hydrocarbon:

$$R_4P{\cdot}OH=R_3PO+R{\cdot}H.$$

The alkylphosphinic acids are colourless crystalline compounds, readily soluble in water or alcohol, and dibasic, whereas the dialkylphosphinic acids are monobasic.

Oxides.—Three oxides are well defined, viz , P_4O_6, P_2O_4, P_4O_{10}; others (*e.g.,* P_4O and P_2O) have been described and also disputed. *Phosphorus oxide,* P_4O_6, is a product of the limited combustion of phosphorus in air; if the element is burned in a hard glass tube and a rapid current of air is passed over it, the oxide may be condensed in a metal condenser and removed later by warming it. It sublimes in feathery crystals and melts at 22° to a colourless mobile liquid of sp.gr. 1·936 and boiling point 173°. Vapour-density determinations indicate the formula P_4O_6; above about 300° in a sealed tube it decomposes to phosphorus and the tetroxide. It is slowly oxidized by air and rapidly by oxygen (with inflammation at 70°) to phosphoric oxide; with cold water it slowly gives phosphorus acid, but with hot water it reacts violently, forming phosphorus, phosphine, phosphoric acid, and other products; hot alkalis decompose it similarly, but cold dilute alkalis form phosphites. Chlorine or bromine converts it chiefly to $POCl_3$ or $POBr_3$, whereas iodine forms the di-iodide, P_2I_4, and P_4O_{10}; hydrogen chloride and phosphorus pentachloride react with it as follows:

$$P_4O_6+6HCl=2PCl_3+2H_3PO_3;\quad P_4O_6+6PCl_5=4PCl_3+6POCl_3.$$

It combines violently with sulphur to give $P_4O_6S_4$ which sublimes as highly lustrous plates (m.p. 102°; b.p. 295°) and which is readily decomposed by water to sulphuretted hydrogen and phosphoric acid. Ammonia reacts to give the diamide $P(OH)(NH_2)_2$ and its ammonium salt. Phosphorus oxide has a peculiar garlic-like odour and is very poisonous; the odour and toxicity of phosphorus vapour are probably due to this oxide. *Phosphorus tetroxide,* P_2O_4 or better $(PO_2)_n$ since its molecular complexity is not certain, is obtained (*see* col. 1) as lustrous, deliquescent crystals; it is not the anhydride of hypophosphoric acid (*see* below), for water decomposes it to phosphorus and phosphoric acids. *Phosphoric oxide,* phosphoric anhydride (loosely termed "pentoxide"), is P_4O_{10} even at very high temperatures; it is obtained by the burning of phosphorus in excess of air or oxygen, as a soft flocculent powder which sublimes to transparent monoclinic crystals. It reacts violently with water and can be reduced to the element by heating with carbon.

Acids.—Hypophosphorous and hypophosphoric acids, H_3PO_2 and $H_4P_2O_6$ (or H_2PO_3), have no known anhydrides; phosphorous acid, H_3PO_3, is derived from P_4O_6; meta-, pyro- and orthophosphoric acids are derived from P_4O_{10} and are described under PHOSPHATES; perphosphoric acids, H_3PO_5 and $H_4P_2O_8$ are also known. *Hypophosphorous acid,* $H_2PO(OH)$, is prepared as its barium salt by boiling phosphorus with baryta water, removing excess of baryta by passing in carbon dioxide, and crystallizing the filtrate; if this salt is decomposed by the calculated amount of dilute sulphuric acid, the pure acid can be obtained, by careful evaporation of the filtrate under reduced pressure, as white crystals melting at 26·5° C. It is a monobasic acid and is slowly oxidized in air; on heating it gives phosphine and phosphoric acid. It is usually sold as a solution of sp.gr. 1·137 (about 32%) which is fairly stable. When warmed with copper sulphate solution it produces a red precipitate of the hydride, Cu_2H_2, thus demonstrating its exceptionally strong reducing properties; its salts are also effective reducing agents. *Phosphorous acid,* $H{\cdot}PO(OH)_2$, is formed from its anhydride, P_4O_6, or by passing chlorine into melted phosphorus covered with water, the phosphorus trichloride being decomposed *in situ.* The crystals melt at 70°, are very deliquescent, and oxidize in the air; on heating they give phosphine and phosphoric acid. It is an energetic reducing agent and, although normally dibasic, it gives rise to organic esters of the type R_3PO_3.

Hypophosphoric acid, $H_4P_2O_6$ or H_2PO_3, occurs among the products of oxidation of phosphorus in moist air or in water; the solution is neutralized by sodium carbonate, and the sparingly soluble lead salt is made, and then decomposed by hydrogen sulphide; sticks of phosphorus immersed in copper nitrate solution are also oxidized to this acid by means of nitric acid. The aqueous solution of the free acid is stable, but it decomposes on concentration unless this be done in a vacuum, in which case the hydrate ($H_4P_2O_6$, $2H_2O$) separates and can be dried below 50° to give the acid; this melts at 70° and decomposes. The solution does not readily act as a reducing agent. Owing to uncertainty as to the constitution, formulae such as $PO(OH)_2{\cdot}O{\cdot}PHO(OH)$ and $PO(OH)_2$ have been proposed; an ester $(CH_3)_2PO_3$ is known (Rosenheim, 1910), so the salts are probably best regarded as derived from the polymerized acid. Permono- and perdi-phosphoric acids are obtained from phosphoric anhydride or meta- or pyro-phosphoric acids and hydrogen peroxide at 0° C, large excess of peroxide favouring the production of the di-acid. The salts are also obtained by electrolysis of dipotassium hydrogen phosphate, a high anode current density increasing the proportion of the permono-salt; $K_4P_2O_8$ forms good crystals. The two acids differ in their action on iodides, the permono-acid liberating iodine at once, and the other slowly (compare persulphates; *see* SULPHUR).

Halogen Compounds.—*Phosphorus trifluoride,* PF_3, obtained by direct union of its elements, is a colourless, non-fuming gas, which liquefies at $-10°$ under 20 atmos., solidifies at $-160°$, and boils at $-95°$. It is comparatively stable, is only slowly decomposed by water, and does not attack glass when cold. *Phosphorus pentafluoride,* PF_5, results from combustion of the element or trifluoride in excess of fluorine, or from the interaction of arsenic trifluoride and phosphorus pentachloride. It is a colourless fuming gas of b.p. $-75°$ and m.p. $-83°$, and is dissociated by large induction sparks but not by heat (compare PCl_5 and PBr_5); it is readily decomposed by water

$$(PF_5+4H_2O=5HF+H_3PO_4)$$

and combines with ammonia to give $2PF_5,5NH_3$. *Phosphoryl fluoride,* POF_3, is best obtained by heating powdered cryolite with 1½ times its weight of phosphoric anhydride; it is a colourless, fuming gas of m.p. −68° and b.p. −40°.

Phosphorus trichloride, PCl_3, obtained by passing a slow stream of chlorine over heated red phosphorus or through a solution of yellow phosphorus in carbon disulphide and fractionally distilling the product, is a colourless, mobile liquid of sp.gr. 1·613 (at 0° C) and b.p. 76°, and freezes at −112°. As prepared above, it may be contaminated with PCl_5, from which it is freed by distillation from excess of phosphorus. Cold water gives hydrochloric and phosphorous acids, and hot water gives red phosphorus and other products. When diluted with hydrogen and led into liquid ammonia, PCl_3 yields $NH{:}P{\cdot}NH_2$, which gives $P_2(NH)_3$ on heating; a similarly diluted mixture, when submitted to the electric discharge, forms the dichloride, P_2Cl_4, an unstable fuming liquid, boiling and decomposing at 180°. *Phosphorus pentachloride,* PCl_5, obtained by the action of excess of chlorine on the element or its trichloride, is a pale straw-coloured solid, which sublimes and dissociates on heating, but may be melted at 148° under pressure; the dissociation is repressed by excess of chlorine: $PCl_5 \rightleftarrows PCl_3+Cl_2$. Water effects decomposition rapidly in two stages:

$$PCl_5+H_2O=2HCl+POCl_3;\quad POCl_3+3H_2O=3HCl+H_3PO_4.$$

The pentachloride is extensively used in organic chemistry, *e.g.*, for replacing hydroxyl groups by chlorine:

$$R{\cdot}OH+PCl_5=RCl+POCl_3+MCl.$$

Phosphoryl chloride, or phosphorus oxychloride, $POCl_3$, may be produced as shown above, or by the interaction of phosphoric oxide on the pentachloride or on hydrogen chloride:

$$3PCl_5+P_2O_5=5POCl_3;\quad 2P_2O_5+3HCl=POCl_3+3HPO_3.$$

It is a colourless liquid of b.p. 107° and m.p. 1°; with water it gives hydrochloric and phosphoric acids, with dilute alcohol ethylphosphoric acid, $C_2H_5{\cdot}H_2PO_4$, and with absolute alcohol triethyl phosphate, $PO(OC_2H_5)_3$. *Pyrophosphoryl chloride,* $P_2O_3Cl_4$, is also known. *Thiophosphoryl chloride,* $PSCl_3$, is formed by direct combustion of sulphur and PCl_3, by the action of sulphuretted hydrogen, antimony trisulphide or phosphorus pentasulphide upon P_4O_{10}, or by dissolving phosphorus in sulphur chloride and distilling: $2P+3S_2Cl_2=4S+2PSCl_3$. It is a colourless liquid (b.p. 125°), is decomposed by water to acids corresponding to each of the three elements, and gives thiophosphates with alkalis, *e.g.*, $PS(OK)_3$.

Phosphorus tribromide, PBr_3, prepared by passing bromine vapour (diluted with carbon dioxide) over phosphorus, or by mixing solutions of the two in carbon disulphide and distilling, is a liquid boiling at 173° and resembling the trichloride chemically. The *pentabromide,* PBr_5, resulting if an excess of bromine is used in the above preparations, is a yellow solid closely resembling the pentachloride. *Phosphoryl bromide,* $POBr_3$ (m.p. 45°; b.p. 195°), and *thiophosphoryl bromide,* $PSBr_3$ (m.p. 38°), both resemble the corresponding chloro-compounds. The action of iodine and phosphorus when dissolved in carbon disulphide (free from sulphur) gives rise to a *di-iodide,* PI_2 or P_2I_4 (m.p. 124°), a *tri-iodide,* PI_3 (m.p. 61°), and possibly a *sub-iodide,* P_4I.

SULPHUR AND NITROGEN COMPOUND

Sulphur Compounds.—Phosphorus and sulphur combine energetically to form a series of sulphides, three of which are well defined, viz., P_4S_3, P_4S_7 and P_2S_5 (*see* A. Stock, *Berichte,* 1908 *et seq.*); the first is sometimes used as a substitute for phosphorus in matches, and the last finds application in organic chemistry for replacing oxygen by sulphur. There is also evidence for the existence of PS_6, P_2S_3, and possibly P_2S. Thiophosphates (*e.g.*, Na_3PSO_3 and $Na_3PS_2O_2$) result from the dissolution of P_2S_5 in alkalis, whereas by melting it with the sulphides or chlorides of heavy metals, salts analogous to Na_3PS_4 are obtained, which are somewhat unstable in water and still more so towards acids.

Nitrogen Compounds.—Phosphorus pentachloride reacts readily with ammonia to give PCl_5, $5NH_3$ and thence $PCl_3(NH_2)_2$, chlorophosphamide, which is decomposed by water to $PO(NH)(NH_2)$ or by heat to "phospham," $NH{:}P{\vdots}N$, a white infusible, stable solid; when $PO(NH)(NH_2)$ is heated it gives "phosphoryl nitride," $O{:}P{\vdots}N$. When ammonia and phosphorus pentasulphide react at a red heat they give a *nitride,* P_3N_5, whereas if the pentoxide is used (in the presence of a trace of water) a series of amides of phosphoric acid result: $PO(NH_2)_2(OH)$, $PO(NH_2)(OH)_2$ and $PO(OH)(NH)$. The interaction of phosphorus pentachloride and ammonium chloride in a sealed tube produces a series of chloronitrides, $(PNCl_2)_n$, where *n* may be 3, 4, 5, 6 or 7. These give rise to a great variety of complex polymerized compounds by reaction with water.

Therapeutics and Toxicology.—Various preparations of phosphorus are used in the British Pharmacopoeia. The element is essential for the growth of bones in young animals, and hence its compounds are used in rickets. It is also efficient as a nerve tonic in paralysis agitans, locomotor ataxia, impotence and nervous exhaustion. In some skin diseases, such as psoriasis, chronic eczema and acute indurata, phosphorus is useful. The hypophosphites are recommended in pulmonary affections and are used in tonics, and the glycero-phosphates stimulate metabolism. Dilute phosphoric acid is used as a gastric stimulant.

Phosphorus is readily accessible in poisonous forms, *e.g.*, in vermin pastes and some matches, and is often taken either intentionally or accidentally. Symptoms of acute poisoning are usually shown after some delay, with nausea, vomiting, and burning sensations in the oesophagus, stomach and abdomen. Emetics and purgatives should be given at once to prevent absorption of the poison. Doses of 3–5 grains of copper sulphate in water at intervals of a few minutes form the harmless copper phosphide. The stomach should be washed out with warm water and then with a 2% solution of potassium permanganate, and this solution should also be given as an enema. Oils, which are effectual in other cases of irritant poisoning, *should not be given,* for they tend to dissolve phosphorus and retain it in the system; the old French oil of turpentine, however, acts as an antidote in allaying the toxic effects. When yellow phosphorus was used in matches, those engaged in the manufacture used to suffer from a form of necrosis, called "phossy jaw" in England; the red form now employed is, however, non-poisonous. (A. D. M.)

PHOTIUS (*c.* 820–891), patriarch of Constantinople (858–867 and 878–886). The way to public life was probably opened for him by the marriage of his brother Sergius to the princess Irene, sister of Theodora, who, upon the death of her husband Theophilus in 842, had assumed the regency of the empire. Photius became captain of the guard and subsequently first imperial secretary. The dissensions between the patriarch Ignatius and Bardas, the uncle of the youthful Emperor Michael III., brought promotion to Photius. Ignatius was arrested and imprisoned (Nov. 858), and upon refusing to resign his office was illegally deposed, while Photius, although a layman, received all the necessary sacerdotal orders within six days, and was installed as patriarch in his place. Ignatius, continuing to refuse the abdication which could alone have given Photius's elevation a semblance of legality, was treated with extreme severity. His cause was subsequently espoused by Pope Nicholas in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions; and when in 863 Nicholas finally anathematized and deposed him, he replied by a counter-excommunication. Meanwhile, the situation was suddenly changed by the murder of Photius's patron, Bardas, by order of the emperor Michael, who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued; he was removed from his office and banished about the end of September 867, a few days after the accession of Basil, and Ignatius was reinstated on Nov. 23.

About 876 Photius was suddenly recalled to Constantinople and entrusted with the education of Basil's children. On the death of Ignatius, probably in October 878, Photius again became patriarch. In 879 the legates of Pope John VIII. attended a synod convened at Constantinople, prepared to acknowledge Photius as legitimate patriarch, a concession for which John was

much censured by Latin opinion. But John stood firm on outstanding points of difference; disowned his legates, and again excommunicated Photius. Photius ignored John's action, but a palace revolution caused his banishment (886) to Bordi in Armenia. He is said to have died there on Feb. 6, 891.

Photius shows to no little advantage as an ecclesiastical statesman. His firmness was heroic, his sagacity profound and farseeing; he supported good and evil fortune with equal dignity; and his fall was on both occasions due to revolutions beyond his control. In erudition, literary power, and force and versatility of intellect he far surpassed every contemporary.

The most important of the works of Photius is his renowned *Bibliotheca* or *Myriobiblon* (ed. I. Bekker, 1824–1825), a collection of extracts from and abridgments of 280 volumes of classical authors (usually cited as *Codices*), the originals of which are now to a great extent lost. To Photius we are indebted for almost all we possess of Ctesias, Memnon, Conon, the lost books of Diodorus Siculus, and the lost writings of Arrian.

The *Lexicon* (Λέξεων Συναγωγή), was probably in the main the work of some of his pupils. The only ms. of the *Lexicon* is the Codex Galeanus, at Trinity College, Cambridge (ed. S. A. Naber, 1864, with introduction on the authorities, critical commentary and valuable indexes). The *Amphilochia* is a collection of some 300 questions and answers on difficult points in Scripture, addressed to Amphilochius, archbishop of Cyzicus (ed. Sophocles Oeconomus, Athens, 1858). Other similar works are his treatise in four books against the Manichaeans and Paulicians, and his controversy with the Latins on the Procession of the Holy Spirit. His *Epistles* were edited by J. Valettas, London (1864). A large number of his speeches and homilies have been edited by S. Aristarches (1900). The only complete edition is Bishop Malou's in Migne's *Patrologia graeca*, ci.–cv. R. Reifzenstein (*Der Anfang des Lexikons des Photius*, 1907) has published a hitherto unedited ms. containing numerous fragments from various verse and prose authors.

See Cardinal Hergenröther, *Photius, Patriarch von Constantinopel* (1867–69).

PHOTOCHEMISTRY is that division of physical chemistry which deals with the chemical action of radiant energy on matter, and with the direct production of radiation by chemical reactions. The field of photochemistry might be regarded as being equally as extensive as the range of electromagnetic vibrations; from the tiny ultra-X-rays to the huge waves of "wireless." Actually, limitations exist and photochemical reactions are considered primarily as the transformations of matter associated with radiations between and including the trans-ultraviolet and infra-red radiations. This range includes the visible radiations, and a band on either side of approximately the same width as that covered by the visible radiations. The wave-lengths included are those between 10$\mu\mu$ and 1,000$\mu\mu$. The micron, μ, a measure of length, is 10^{-4} cm. or 10^{-3} mm., and the millimicron, $\mu\mu$, is 10^{-7} cm. or 10^{-6} mm. The direct production of radiation by chemical reaction is termed *chemiluminescence*. It is differentiated from the radiation produced in such reactions as combustion, by the absence of thermal equilibrium between the matter and the radiation concerned (*see* RADIATION).

Principle of Photochemical Equivalence.—Previous to about 1910, photochemistry had but one accepted generalization, the *absorption law*, according to which only the light energy absorbed by a body is active in promoting chemical change. This is a special case of the principle of conservation of energy, which states that energy may be neither created nor destroyed. Nearly a century after the first expression of this law, a principle of photochemical equivalence was put forward, in 1922, by A. Einstein. It is founded on Planck's quantum theory (*see* QUANTUM THEORY) of radiation, according to which all exchange of energy as radiation between atoms and molecules takes place discontinuously by quanta of finite magnitude $\epsilon = h\nu$, where ν is the frequency of vibration, h a universal constant, equal to $6{\cdot}55 \times 10^{-27}$ ergs/sec.; ϵ varies continuously in magnitude with the multiplying frequency ν, but Planck's h is an invariable *quantum* of *action*.

The photochemical equivalence principle of Einstein states that in a primary photochemical process, the decomposition of one molecule requires one quantum of energy $h\nu$, or that one gram-molecule requires $Nh\nu$, where N is Avogadro's number of gas molecules per litre, $6{\cdot}06 \times 10^{23}$. In his original derivation he postulates a reversible reaction of simple unimolecular decomposition

$$AB + h\nu \rightleftharpoons A + B,$$

the bimolecular "dark" reverse reaction giving the chemiluminescent radiation $h\nu$; the reaction was supposed to occur in a gaseous or dilute system. In a later deduction, this primary photochemical event was supposed to be limited to the excitation of an atom or molecule

$$C + h\nu \rightleftharpoons C^*$$

the atom or molecule C being raised to a higher energy level. It may be stated at once that this generalization is not so complete or sufficient that all photochemical phenomena can be interpreted by its sole aid. It has, none the less, completely changed the outlook, beside leading to improvements in the technique.

Experiment and Technique.—Modern investigation of a photochemical reaction essentially involves determining its quantum efficiency, in the sense of Einstein's principle. This requires certain elements of technique:—(a) a light source of sufficient intensity adequately monochromatized; (b) exact measurement of the energy absorbed during a given reaction period; (c) distinction of the primary photochemical reaction, if possible, from secondary dark reactions; (d) determination of the molecular "order" of the reaction involved, and analytical measurement of the product of the photochemical reaction proper.

As to the first, there are not many available reactions occurring in light of the visible spectrum range. As visibility coincides fairly closely with the spectral distribution of energy in sunlight—a matter of natural selection—it is obvious that on the whole only systems stable in such illumination will be readily found. Much more frequent are photochemical reactions in the ultraviolet; and artificial light sources rich in these rays are most used in laboratory research, as well as for certain industrial applications. The ultra-violet radiation from electric glow lamps is relatively feeble and does not extend far to the shorter waves. Recourse has to be made to spark and arc discharges. The latter are generally more convenient. The three chief types used may be described as carbon arcs, magnetite and high-melting metal arcs, as tungsten arcs, and metal vapour arcs; of these, the mercury vapour arc in fused quartz is the most important. The spectrum is discontinuous, and it is not difficult to secure approximately monochromatic light at several different wavelengths by the use of colour screens or ray filters. Unfortunately when the far ultra-violet rays are in question (λ less than 200 $\mu\mu$) there are no very satisfactory filters available, the best requiring the use of chlorine and bromine gases. When a high degree of monochromatic purity is required, the light must be dispersed and quartz monochromators employed, with great reduction of intensity. With regard to the other requirements, the measurement of the energy absorbed in a reaction is determined with a radiometer (*q.v.*, such as a thermopile, radiomicrometer or bolometer) as the difference between the energy incident upon and transmitted through the reaction mixture; the latter is usually contained in a vessel with plane-parallel quartz walls, and maintained at constant temperature. The distinction of the primary photochemical reaction, the determination of the molecular order and of the quantum efficiency are then matters of interpreting the analytical results for different periods of the reaction.

The fundamental researches on photochemical equivalence were those of E. Warburg. They occupy in the modern era of photochemistry somewhat the position of the classical photochemical investigations by Bunsen and Roscoe in preceding years. Warburg introduced a convenient term, the *quantum efficiency*; this is the ratio of the effective photochemical equivalent ϕ to the ideal photochemical equivalent P. Both ϕ and P are expressed in terms of the number of gram-molecules absorbing and decomposed by one gram-calorie of radiation of frequency ν. When Einstein's law holds $\phi/P = 1$. Tabulated results of several reactions show that relatively few reactions confirm the Einstein relation, among which are some for which the efficiency is actually less than unity, but which give this value when extrapolated back to the start of the reaction. This procedure is justifiable when

strongly absorbing product is formed. On the other hand there are many reactions whose efficiency (ϕ/P) is much greater than unity, even to hundreds and thousands of molecules per quantum.

Mechanism of Photochemical Reactions.—Although it is true that certain substances are more obviously photosensitive than others, a useful classification of photochemical reactions is not possible in terms either of chemical structures or of types of chemical reaction. This is particularly evident in the field of organic chemistry. The great variety of substances and types of reaction is illustrated in the following table:

Allotropic change in elements	Sulphur Light Rhomb. ⇄ Amorph.
Intramolecular change and isomerization .	Infra red Fumaric acid: COOH—C—H ∥ H—C—COOH ⇄ Maleic acid: H—C—COOH ∥ H—C—COOH
Polymerization and depolymerization .	$C_{14}H_{10}$ ⇄ $C_{28}H_{20}$ Anthracene ⇄ Dianthracene $3O_2 \rightleftharpoons 2O_3$ Oxygen Ozone
Hydrolysis . .	$(CH_3)_2{\cdot}CO + H_2O = CH_3{\cdot}COOH + CH_4$ Acetone Water Acetic acid Methane
Reduction . .	$2AgCl = Ag_2 + Cl_2$ Silver chloride Silver Chlorine $Fe_2(C_2O_4)_3 = 2Fe(C_2O_4) + 2CO_2$ Ferric oxalate Ferrous oxalate Carbon dioxide
Oxidation . .	$PbS + 2O_2 = PbSO_4$ Lead sulphide Oxygen Lead sulphate
Decomposition .	$2HI = H_2 + I_2$ Hydriodic acid Hydrogen Iodine
Synthesis . .	$CO + Cl_2 = COCl_2$ Carbon monoxide Chlorine Phosgene

To obtain a classification it is therefore necessary to search more deeply into the fundamental mechanisms of photochemical reactions. Every advance in knowledge of these will displace a previous classification or system but will supply a better working hypothesis. Einstein's proof of his principle implied that the *primary photochemical process* is a dissociation of a molecule, *e.g.*, into atoms. Thus in the combination of hydrogen, H_2, and chlorine, Cl_2, in light to form hydrogen chloride, HCl, it was assumed that the primary reaction was $Cl_2 + h\nu = Cl + Cl$. Now the photochemical efficiency of the $H_2.Cl_2$ reaction is very great—it can amount to thousands of molecules of HCl per quantum absorbed. This was explained by the conception of secondary reaction chains (*see* subsequent section). Primary decomposition of molecules also implies a wave-length limit to a given photochemical reaction; because if the quantum, $h\nu$, absorbed be of less energy than the heat of formation of the molecule, it should be impossible to decompose it directly, and therefore, according to Einstein's principle, the relation of photochemical yield ϕ to the wave-length would have the form shown in fig 1.

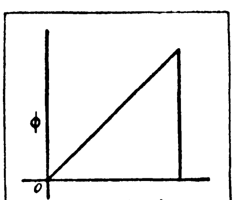


FIG. 1.—DIAGRAM SHOWING HOW PHOTOCHEMICAL YIELD SHOULD INCREASE WITH WAVE-LENGTH

Now cases are certainly known where the wave-lengths active in photochemical change are below the value corresponding to the heat of formation. In fact, the existence of definite photochemical spectrum thresholds has scarcely been demonstrated.

A difficulty of exactly the opposite kind for the primary decomposition of the molecule developed from the investigations of physicists on the energy required to make gas molecules fluoresce. It was shown that at low pressures a molecule of gas can take up many times its heat of formation without decomposing. For example, iodine, I_2, can absorb and re-emit as resonance-radiation an amount of energy five times its heat of formation. On the modern theory of atomic and molecular structure as related to the emission and absorption of light, named, after its principal founder, the Bohr theory (*see* ATOM), these results are explained as follows. The total internal energy of a molecule, however acquired (and understanding by a molecule a multinuclear structure) will consist of:

Energy of rotation + Energy of oscillation + Energy of electron displacements.

The whole energy, and the distribution of this energy, is governed by quantum rules, *i.e.*, it cannot vary continuously, but can only assume a series of finitely differing values, or quantum states. The gain of internal energy of an excited molecule consists primarily in the exaltation of the electron system to higher quantum states, when the oscillation and rotation energies are also altered by the coupling of their periods with those of the electron system. The rotational and oscillation energies are mainly responsible for absorption and emission of infra-red rays. At present there is but slender evidence for direct intervention of these in chemical reactions. A primary chemical decomposition, *i.e.*, one not involving collision with chemically indifferent molecules, might occur by such increase of rotational energy that the centrifugal force exceeded the chemical affinity. Similarly for an excessive increase of oscillation of the parts. Apparently the constitution of molecules is such that this cannot be effected either by direct infra-red absorption or by absorption in the bands corresponding to electronic displacements, but only at frequencies beyond the band spectrum. (A typical molecular band spectrum is illustrated in the article BAND SPECTRA, *q.v.*) The theory of such spectra is not yet entirely adequate to complete prediction of the distribution of energy in all cases. But certain conclusions are definite. The change in rotational energy on excitation is small enough to be negligible, so that it is quantum-coupled increase of oscillation energy that is critical for dissociation.

The Dissociation of the Molecule.—In the gaseous or independent state, molecules may be classed as heteropolar and homopolar or non-polar (*see* ELECTROLYSIS), the former having large electrical moments. In the homopolar molecules no such electrical dissymmetry appears. However, not only are molecules of all sorts of intermediate type known, but the polarity of one and the same molecule depends on its environment. If a heteropolar molecule, such as HBr, absorb energy, the increase of oscillation energy is small. An electron of the positive ion is raised to a higher quantum state, thereby inducing stronger, not weaker binding, and no dissociation, *e.g.*, into positive and negative ions, can be expected from the absorption of light. It is not impossible, however, that an electron should be removed from the anion by radiation, although spectra corresponding to the reaction

$$\underset{\text{Chlorine Atom}}{Cl} + \underset{\text{Electron}}{\odot} \leftrightarrows \underset{\text{Chloride Ion}}{\overline{Cl}}$$

termed *electron affinity spectra* are not yet known. In such case we should have dissociation of the molecule into a positive ion, a neutral atom, and an electron, thus:

$$(HBr) \rightarrow \overset{+}{H} + Br + \odot.$$

In homopolar molecules Franck suggests two types of linkage. In one, electrons are shared in common (covalency), *e.g.*, in H_2 and O_2; "such molecules cannot separate from the normal state adiabatically into two atoms, and the electron jumps associated with the formation and dissociation of these molecules cannot be produced by radiation processes but only through collision." In agreement with this no point of convergence of bands has been observed in the molecular spectrum of hydrogen. A second type of homopolar linkage is, however, of much smaller strength—sometimes termed van der Waal's forces, *i e*, akin to the attraction between gas molecules and the chemist's residual affinity operative in molecular association. Here the molecule may take up so much oscillation energy through absorption that it will separate into a normal and an excited atom. There is evidence that the halogen molecules belong to this class. The absorption

spectrum of iodine, which is approximately represented in fig. 2, indicates that the shorter the wave-length, the smaller the interval between the oscillation-quanta, until a real convergence limit appears at about 5,000 Å.U. with a strong continuous spectrum beyond. The Ångstrom unit, Å.U., $= 10^{-8}$ cm. $= 0 \cdot 1 \mu\mu$. Bromine and chlorine also show continuous spectra, of known wave-length limits, 5,200 Å.U. for Br_2 and 4,800 Å.U. for Cl_2. This con-

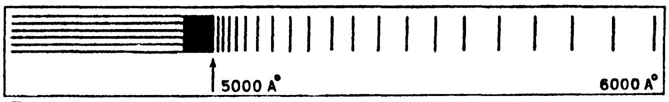

FIG. 2 —DIAGRAMMATIC REPRESENTATION OF A PORTION OF THE ABSORPTION SPECTRUM OF IODINE

vergence limit seems to be critical for dissociation of the molecule; and it may be assumed that *absorption of light of wave-length equal to or shorter than these convergence limits of the band spectra will dissociate the molecule into a normal and an excited atom.* Recent work indicates that the absorption spectrum of oxygen, O_2, is similar to that of iodine but the continuous spectrum lies at a much shorter wave-length. Furthermore, the ultra-violet absorption spectra of HBr and HI during photochemical decomposition were found to be continuous. Hence it is concluded that these molecules also are directly dissociated into atoms by light absorbed in this region.

Types of Photochemical Reaction.—On the basis of comparison of the absorption spectrum with actual photochemical behaviour, we have then a very important division of photochemical reactions into two classes. (This division was clearly suggested by J. Franck, "Elementary Processes of Photochemical Reactions," *Faraday Soc. Symposium*, but more explicitly developed by R. H. Gerke, *J. Amer. Chem. Soc.*, 1927, 49, p. 2671.) In one class, the molecule is merely converted by absorption of radiation into an "excited" molecule,

$$AB + h\nu \rightleftharpoons A^*B.$$

The resultant excited molecule may: (*a*) lose energy by radiation (fluorescence, resonance radiation), or (*b*) lose energy by collision with another molecule, in which case a number of things may happen. The most likely is conversion to heat, as energy of translational motion. The broadening of absorption lines in gases with pressure, and in solutions, the reduction of fluorescence by inert gases, are evidence of energy "damping" of this kind. Another possibility, however, is collision not with an indifferent molecule, but with an acceptor, *i.e.*, a molecule capable of reacting with the excited molecule, or of itself undergoing chemical change. In all cases where the excited molecule itself appears in the photo-product, we have what has been conveniently termed (R. H. Gerke, *loc. cit.*) the *excited reactant* type of photochemical reaction. Some examples are given in the following table:

Reaction	Absorbing molecule	Type of spectrum	Active radiations, Å.U.	Quanta absorbed per mol. of reaction	Heat effect of reaction
$O_2 = 2/3\ O_3$	O_2	Band	1,970–1,756	1·04–3·4	Endothermic
$NH_3 = 1/2\ N_2 + 3/2\ H_2$	NH_3	,,	2,260–1,515	2–10	,,
$O_3 = 3/2\ O_2$	O_3	,,	6,700 and u.-v.	.	Exothermic
$H_2 + 1/2\ O_2 = H_2O$ (dry)	O_2	,,	1,970–1,756	..	,,
$CO + 1/2\ O_2 = CO_2$ (dry)	O_2	,,	1,970–1,756	..	,,
$CH_3 \cdot CHO + 1/2\ O_2 = CH_3 \cdot COOH$	$CH_3 \cdot CHO$	,,	2,800–2,350	..	,,

Where, however, the excited molecule does not itself enter into chemical reaction, but colliding with another different molecule induces chemical change in this, we have an *excited sensitizer* or photocatalysed reaction. The first cases of gas reaction of this type were discovered by F. Weigert (1907), being a number of reactions in which chlorine gas in light produced decompositions or combinations without appearing in the products. A notable example was the sensitized decomposition of ozone by chlorine. Recent experiments on the excitation of mercury vapour in ultra-violet light have widened the field of these reactions and helped to clarify their nature. In experiments on the excitation of gas molecules or atoms by electrons of known velocity (voltage), it was found that for a certain velocity of the electron a bombarded atom became excited and emitted radiation of definite wave-length. The system of the atom plus electron lost kinetic energy just equal to the quantum radiated. But conversely, a slow moving electron colliding with an excited atom might gain kinetic energy, the atom becoming normal without radiating. Such collisions are termed "rayless collisions of the second kind." The same kind of rayless transfer of quantized energy was also found to be possible between atoms and molecules in gases. Cario and Franck showed that mercury atoms, excited by the resonance line λ 2537, could transfer their excess energy to hydrogen molecules, with production of "active" hydrogen, very possibly atomic hydrogen, according to the reactions

$$Hg + h\nu \rightarrow Hg^*$$
$$Hg^* + H_2 \rightarrow Hg + 2H.$$

A considerable number of such mercury sensitized reactions have now been investigated by H. S. Taylor and others. The intermediate "active" hydrogen has been caused to decompose ethylene, C_2H_4, carbon monoxide, CO, forming formaldehyde, solid polymers, and methane. Some of these excited sensitizer reactions are here tabulated:

Reaction	Absorbing sensitizer	Type of spectrum	Active radiation, Å.U.	Quanta of radiation per mol. reactant	Heat effect of reaction
$H_2 = 2H$	Hg	Line	2,536		Endothermic
$O_3 = 3/2\ O_2$	Hg	,,	2,536	.	Exothermic
$H_2 + 1/2\ O_2 = H_2O$	Hg	,,	2,526	..	,,
$N_2O_5 = N_2O_4 + 1/2\ O_2$	NO_2	Band	4,600–4,000	.	Negligible

In both these "excited molecule" reactions, the chemical yield on the photochemical equivalent basis will very probably not agree with the Einstein equivalence principle, because the excited molecule may lose energy either by fluorescence or by ineffective collisions. Yet the primary event, formation of an excited molecule, is itself regulated by the photochemical equivalence. If, however, the absorbed frequency is equal to or greater than the convergence limit of the band spectrum of the substance, absorption takes place with *primary decomposition:*

$$\text{Atom} + h\nu = \text{Ion} + \text{electron}$$
$$\text{Molecule} + h\nu = \underset{\text{(excited)}}{\text{Atom}^*} + \underset{\text{(normal)}}{\text{atom}}$$

and here the yield is in full agreement with Einstein's law. It appears therefore that when absorption takes place of frequencies still low enough for the atom or molecule to resonate, photochemical reaction need only follow indirectly. When, however, the radiation "note" is pitched too high for the system to resonate, the atom or molecule is shattered.

Chain Reactions.—In many exothermic photochemical reactions it is found that the photochemical efficiency may be manifold, up to 10^6 molecules per quantum absorbed. The most fully studied, though still incompletely unriddled, example is the union of chlorine and hydrogen in light:

$$H_2 + Cl_2 = 2HCl.$$

In the completest possible absence of water vapour, this reaction does not proceed in ordinary and ultra-violet light within the band spectrum of chlorine, but does so in ultra-violet light at

3,000 Å.U. In the first case, only an excited Cl_2^* molecule is formed, which is unable to activate hydrogen in absence of water. In the second case, primary decomposition into an excited and normal molecule is believed to occur

$$Cl_2 + h\nu = Cl^* + Cl$$

The chain reaction somewhat as proposed by Nernst probably follows:

$$Cl^* + H_2 = HCl + H$$
$$H + Cl_2 = HCl + Cl$$

In the presence of water vapour, even excited molecules can initiate chains of much greater length. This would signify that "activated molecules" or metastable molecular complexes must be formed of much longer life than the 10^{-8} second usually assigned to excited molecules.

The conception of reaction chains to explain high quantum yields was introduced by M. Bodenstein and developed by W. Nernst. In the type just instanced, implying a primary decomposition reaction, a free atom or group is produced. This reacts with one of the original molecules, forming another free atom or group, and so forth. The process is exhausted by the gradual recombination of the free atoms or groups with each other. In another type, an excited molecule is produced, which activates a molecule of reactant by collision. This activated molecule then forms another activated molecule of the product, and so on. There is therefore a succession of rayless transfers of energy, the chain ceasing again by dissipation of energy in fruitless collisions. It is very possible that in certain cases, particularly where water vapour plays a part, metastable intermediate molecules or groups are formed.

Photochemical Induction, Inhibitors and Water Vapour.—The classical investigations of Bunsen and Roscoe upon the photochemical union of chlorine and hydrogen revealed the existence of a "latent period," during which no combination occurred. They regarded this "induction" as common to all chemical reactions, as required for the overcoming of starting friction. Many explanations were offered of "photochemical induction" until D. L. and M. C. C. Chapman showed it to be due to the presence of specific impurities. These suspend or inhibit the reaction until destroyed by the light or the photochemical change itself. In the hydrogen-chlorine reaction, ammonia is an important inhibitor, as are the oxides of nitrogen. Oxygen again can function as an inhibitor, either by itself accepting hydrogen atoms, or by reacting with excited chlorine atoms. In many reactions, substances may act as negative photocatalysts simply by absorbing exciting radiation.

In certain gas reactions, water vapour may appear as a positive catalyst, as for example in the combination of chlorine and hydrogen in visible light. Explanations range from intermediate hydrates (containing active atoms) to facilitation of an action limited to a polar layer on the walls of the reaction vessel.

Photochemistry and Carbon Compounds.—The number of organic syntheses and decompositions capable of being effected by light has been greatly increased as more efficient sources of ultra-violet light become available. Most of these, however, remain quantitatively unprobed, and so far relatively few have become tools for organic synthesis. The most important investigations in this field at present are those concerned with the quantitative measurement and interpretation of absorption spectra (a notable work is V. Henri's *"Études de Photochimie,"* 1925), from which we may anticipate certain approximate inductions on the photochemical reactivity of specific groups (or specific linkages), such as $>C=O$, $>C=S$, $-C=C-$, $N\equiv C-$, etc., either singly, conjugated in chains or condensed. And this may yield a workable knowledge of relations between photochemical reactivity, unsaturation and the life-periods of free radicals. Among synthetic reactions, the photo-polymerizations of vinyl compounds are perhaps the most interesting, because of the relations of such bodies to organic high-molecular colloids, such as the rubber hydrocarbon $(C_5H_8)_x$, starch $(C_6H_{10}O_5)_m$, and cellulose $(C_6H_{10}O_5)_n$ and eventually proteins, $NH_2(CO{\cdot}NH)_mCOOH$.

There are two organic photolyses of quite dominating importance. These are the retinal process underlying vision, and the green leaf assimilation of carbon dioxide. The photochemical basis of vision consists in the bleaching-out of an organic pigment, "visual purple." This is regenerated in darkness by a secondary chemical process, which appears to be molecular in character. We can represent this process by the symbol

$$S \underset{\text{dark}}{\overset{\text{light}}{\rightleftarrows}} P + A$$

Photosynthesis.—The green leaf synthesis of starch, which is the basis of the great photochemical industry of agriculture, is generally emphatically termed photosynthesis. The riddle expressed in the crude equation

$$6(CO_2 + H_2O) = C_6H_{10}O_5 + 6O_2$$

Carbon dioxide + Water form Starch + Oxygen

is by no means solved. The *formaldehyde hypothesis* of Baeyer explains the production of carbohydrates (starches, sugars, cellulose) by a primary formation of formaldehyde

$$CO_2 + H_2O \rightarrow CH_2O + O_2$$

Carbon dioxide + Water form Formaldehyde + Oxygen

by light in the presence of chlorophyll, which is supposed to be followed by a biochemical or photochemical condensation of the formaldehyde

$$6(CH_2O) = C_6H_{10}O_5 + H_2O.$$

This theory has been strongly supported by B. Moore, D. Berthelot, and recently by E. C. C. Baly, and severely criticized by H. A. Spoehr, whose monograph "Photosynthesis" (*American Chem. Soc. Monographs,* 1925) furnishes a very complete study of the subject. The issue is of capital importance for chemistry, perhaps ultimately for the economy of mankind, since it is concerned with the basic process of food production. Baly and his co-workers claim that the reaction:

$$CO_2 + H_2O = CH_2O + O_2$$

can be effected, (*a*) by ultra-violet rays at 2,060 Å.U., (*b*) by sunlight in the presence of dyes such as Malachite Green. They also assert that the condensation of formaldehyde to reducing sugars can be effected by ultra-violet rays at 2,900 Å.U. More recently Baly has published further evidence supporting the production of alkaloids by direct photochemical synthesis *in vitro.*

Meanwhile the work of other investigators, notably O. Warburg, R. Wurmser and H. A. Spoehr, following the pioneer efforts of A. Brown and H. Escombe, has shown the actual photochemical efficiency of the chlorophyll sensitizer to be fairly high, perhaps up to 80% of an absorbed quantum being converted into stored chemical energy at moderate light intensities. *Chlorophyll,* the chemical constitution of which has been unravelled by the masterly work of R. Willstätter, undoubtedly acts as a photo-chemical sensitizer, like the dyes used in photographic processes (*q.v.*).

Industrial Prospects.—The total amount of solar energy incident upon the earth's surface is very great. Taking a *solar constant* of 1·5 calories per sq.cm. per minute, it can be calculated that onto every square mile of the Sahara Desert about 67 billion British Thermal Units of heat are given by the sun in a 6-hour day; the area of this desert is about 2,300,000 sq. miles. If, therefore, only a minute fraction of this heat could be utilized we should be able to realize the prophetic words of a great chemist (G. Ciamician): "The exhaustion of coal will not halt civilization, destined to advance as long as the sun shines. Then our sooty and neurotic age of coal will yield to a purer and calmer epoch, relying upon solar energy for a fortune and a progress without mischance."

PHOTOELECTRICITY. The photoelectric effect is the name given to the power shown by light, X-rays and γ-rays of causing a body to emit electrons, or negative electricity. Light, X-rays and γ-rays are all electro-magnetic radiations differing only in their wave-lengths, that of light being the longest; and it is the electric forces in the radiation, acting on the electrons in the atoms of the body, which communicate sufficient energy to the electrons to set them free from the atom, and even to give them very high velocities. The phenomenon is interesting and important from several points of view, of which the chief is that it represents one of the three fundamental methods of interaction between radiation and matter, the other two being resonance-absorption and scattering. The laws governing this phenomenon are simple to express although difficult to understand, and maintain their validity over an enormous range of wave-length. Ordinary light has a wave-length one million times as great as that of the short γ-rays, but yet the relation governing the speed of the ejected electron is the same in both cases.

The study of the photoelectric effect has raised many points of great interest in connection with our views as to the real nature of radiation, since it brings to light a behaviour apparently irreconcilable with the simple continuous wave-theory used to explain interference. While this disagreement still defies explanation, the effect is sufficiently understood to be of the greatest use in elucidating the structure of the atom. The reason for this lies in the fact that the action of the radiation on an atom is selective. While long wave-length light leads to the ejection of electrons from the outer portions of the atom, the much shorter wave-length X-rays and γ-rays interact chiefly with the innermost electrons. From the nature of this interaction it is possible to obtain information successively about the different electrons in the atom.

The photoelectric effect is not only important from the purely scientific standpoint, but also finds a most important practical application in the construction of the photoelectric cell, which is one of the most trustworthy methods existing for measuring the amount of energy in a beam of light. It has rendered possible the construction of accurate photometers for determining the density of photographic plates, and has given methods for measuring the amount of light emitted by extremely faint stars.

The action of the radiation being to cause the ejection of electrons from atoms, it will be seen that the primary questions regarding each individual process are how fast the electron is ejected and in what direction, and to this must then be added the question of how many electrons are set free each second when radiation of given intensity is incident on matter. More or less satisfactory answers can now be given to these questions, and the history of the subject is best described by reference to those researches which showed how the number and velocity of the electrons depended on the intensity and wave length of the radiation.

Historical and General.—The study of photoelectric effects started in 1887, when Hertz found that ultra-violet light falling on a spark-gap enabled a discharge to pass more easily than when the gap was not illuminated. A year later Hallwachs made the important observation that, while ultra-violet falling on a negatively charged body caused a rapid loss of the charge, no loss of electricity occurred when the body was initially positively charged. It was not very long before the cause of this behaviour was discovered, and in 1899 J. J. Thomson and P. Lenard showed independently that the action of the light was to cause the emission of negatively charged corpuscles identical with the cathode rays in a discharge tube.

In the following years a great deal of work was carried out on this peculiar action of light, and attention was first directed to the intensity of the emission and how it depended on the state of the surface of the metal and on the polarization of the light. In 1902 Lenard opened up a new method of investigation by directing attention to the velocity of the ejected electrons. He was able to show that the maximum velocity of the electrons was independent of the intensity of the light but did depend on the wave-length. He appreciated quite clearly the difficulties this raised in the way of any explanation, since the obvious suggestion of the ejection being due to a transference of energy from the light to the atoms of the metal by some resonance action was rendered impossible by its lack of dependence on the intensity. It was this work which formed the basis of Einstein's famous paper of 1905. Einstein suggested that the general phenomenon of the conversion of light could be better understood on the assumption that the energy of light radiation was not distributed continuously in space. As radiation spread out from a source he imagined it to remain localized in small bundles, or energy quanta, which became further and further apart as they receded from the source, whilst individually remaining unchanged. He pointed out that when an atom absorbed radiation the simplest assumption would be that a light quantum gives its whole energy to an electron. It was natural to associate the energy of the light bundles with the definite amounts of energy postulated by Planck in his quantum theory of black body radiation. Hence Einstein suggested that, at every act of absorption, the energy received by the electron was $h\nu$, ν being the frequency of the radiation and h a universal constant which should be identical with that occurring in Planck's formula for the black body radiation.

It follows therefore that the maximum energy of the electrons ejected by radiation of frequency ν is

$$h\nu - P,$$

where P represents any work that has to be done in removing the electron from the place where it absorbs to the place where it is observed. We may subdivide this further and write w for the work to remove the electron just clear of the atom, and P' for the work to remove the electron clear of the body as a whole. These quantities w and P' have different values and importance according to the region of wave-length concerned. P', the work to remove the electron clear of the body, is intimately connected with the work function occurring in Richardson's thermionic equation, and is negligible except in the case of visible light. The quantity w is far more interesting, and depends on the particular position in the atom from which the electron comes. It is a true atomic constant. Up to a certain point we may imagine the electrons in the atom to be arranged in shells, each shell characterized by a certain energy. To remove an electron from a shell and merely to bring it outside the atom with a vanishingly small energy will require the expenditure of a certain characteristic amount of work, w_1, w_2, w_3, etc., according to whether the electron comes from the first, second or third shell. We see, therefore, that on Einstein's hypothesis, light of frequency ν incident on a collection of such atoms would liberate several groups of electrons of different energies:

$$h\nu - w_1, \quad h\nu - w_2, \quad h\nu - w_3;$$

but that the innermost shells would be untouched if the energy of the quantum $h\nu$ were less than the characteristic energies of the shells w_4, w_5, etc.

It only remains now to write down the expression for the energy of the electron in order to obtain Einstein's famous equation. For low velocities this may be written $\frac{1}{2}mv^2$, but for high velocities near that of light the correct relativity expression must be used. This is

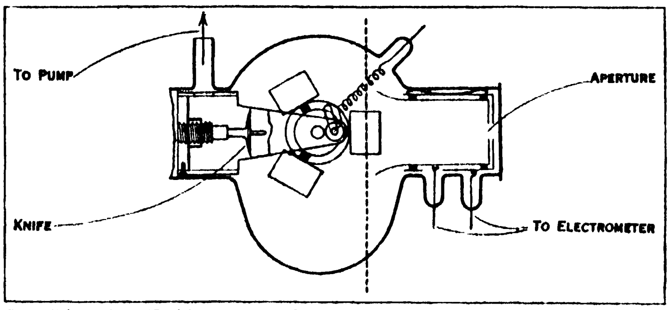
$$mc^2\left(\frac{1}{\sqrt{(1-\beta^2)}} - 1\right),$$

where m is the mass of the electron, c the velocity of light *in vacuo,* and β the velocity of the electron. It is frequently convenient to express this energy by giving the potential fall in volts V an electron β must pass through in order to acquire this energy. Then, if e is the charge on the electron in electrostatic units ($4{\cdot}774\times10^{-10}$), and since 300 volts equal one electrostatic unit of potential, we have finally

$$\frac{V}{300e} = mc^2\left(\frac{1}{\sqrt{(1-\beta^2)}} - 1\right) = h\nu - w.$$

The equation as written here is more explicit than that originally given by Einstein, and considerable research was needed to establish it, but essentially it was all implied in the original paper. The succeeding sections indicate the main steps by which this prediction was shown to be true and how its details were elucidated.

Proof of the Einstein Law for Light.—The law proposed by Einstein connecting the energy of the photoelectron with the



FROM MILLIKAN, "THE ELECTRON" (UNIVERSITY OF CHICAGO PRESS)

FIG. 1.—MILLIKAN'S APPARATUS FOR DETERMINING THE ENERGY OF PHOTO-ELECTRONS LIBERATED BY LIGHT OF KNOWN WAVE-LENGTH

frequency is noteworthy, not only for its simplicity but also because it introduced Planck's constant h into a fresh domain. It was seven years after Einstein had shown his theory agreed in its general lines with Lenard's experiments before it was established definitely by O. W. Richardson, K. T. Compton and also A. L. Hughes that the energy of the emitted electron did increase proportionately with the frequency, and that the constant of proportionality was approximately equal to the value of Planck's constant h obtained by other means. Subsequently Millikan carried out an extensive research which established the relation so accurately that it is now considered to give one of the most trustworthy values for h. This method is typical of the best method of investigation of the photoelectric effect of light and will be described in some detail. The apparatus is shown in fig. 1, and may conveniently be considered in two parts, as divided by the dotted line. Cast cylinders of the alkali metals (sodium, potassium, lithium) were mounted on an axle in a highly evacuated glass vessel. The actual experiment is carried out by the part of the apparatus to the right of the dotted line, light entering through the window, and falling on the metal surface. Previous work had shown that reliable results could be obtained only when the metal had a clean, fresh surface prepared *in vacuo*, and the apparatus on the left of the dotted line consisted of various devices by which the cylinder of alkali metal could be brought opposite the knife, which was then operated by an electro-magnet outside the tube so as to shave off the outer layer of the alkali metal, leaving a fresh uncontaminated surface. Supposing this to be done the cylinder was then rotated to be opposite the window and the actual experiment could begin. A beam of monochromatic light from a spectrometer passed through the window and fell on the prepared surface, leading to the emission of electrons which were collected by the gauze cylinder, on the right side of the apparatus, connected to a quadrant electrometer. If a small positive potential were then applied to the metal block, the electrons would arrive at the gauze with lower energies, owing to the retarding action of the potential. The maximum energy of emission could thus be measured by finding that positive potential V which just sufficed to prevent any electrons arriving at the gauze and communicating their charge to the quadrant electrometer. The maximum energy of the electrons is then Ve, where e is the electronic charge. Millikan showed to an accuracy of one half of 1% that, with each metal, the energy of the emitted electrons varied linearly with the frequency of the light, and that in each case the constant of proportionality was the same, and equal, within the experimental error, to the values obtained for Planck's constant by other methods.

Photoelectric Effect of X-rays or γ-Rays.—The essential distinction between the photoelectric effect of X-rays or γ-rays and that of light lies in the higher frequency of the former radiations and in the correspondingly greater energy of the quantum. The energy given to the atom is now measured in tens of thousands of volts or even hundreds of thousands of volts, and not in tens of volts as in the case of light. It is to be expected that different methods of investigation must be used to meet the changed conditions, but besides this there is a shift of the point of interest. The amount of energy transferred to the electron is so large that the energy lost in getting free of the body as a whole is negligible in comparison, but on the other hand the large energy of the quantum enables electrons to be removed from even the innermost orbits of the atom. Radiation of one frequency can thus give rise to a series of electron groups of different energies, according to whether they are ejected from the outer or inner orbits of the atoms. The electrons from the innermost orbits will have used up the greater portion of their $h\nu$, and will therefore emerge with the lowest velocities, whereas those from the outer levels will have energies close to that of the quantum. It will be realized that there is here an admirable method of investigating the inner structure of the atom. By studying the energies of the different groups of photoelectrons and finding how much less these energies are than that of the original quantum, we can ascertain the orbit from which each electron comes, and the general character of its interaction with light under given conditions.

The general type of apparatus which is used in these investigations is shown in fig. 2. The source of the photoelectrons may be either a thin foil on to which X-rays are fired from outside the box, or a wire coated with radioactive material, which, as will be described later, is a copious emitter of photoelectrons. Above the source is a slit which allows a beam of the electrons to pass. This apparatus is placed in an evacuated box between the poles of a large electromagnet, and on application of the magnetic field the beam of electrons is bent round into circular paths. By this process it will be analysed into its different velocities, since the fastest electrons will describe the largest circles, and the slowest electrons the smallest circles. A record of the velocity spectrum of the photoelectrons is obtained by a strip of photographic plate. This is frequently referred to as the focussing method since, as can be seen from fig. 2, the rays leaving the source within quite a large solid angle are concentrated in one spot on the photographic plate. A reproduction of a photograph was taken recently in this way by Prof. H. H. Robinson.

This type of apparatus does not give lines sharp on both sides but only on the high velocity side, and a series of such lines can be seen on the photograph. These show the various groups of electrons ejected from gold atoms by the characteristic K X-rays of

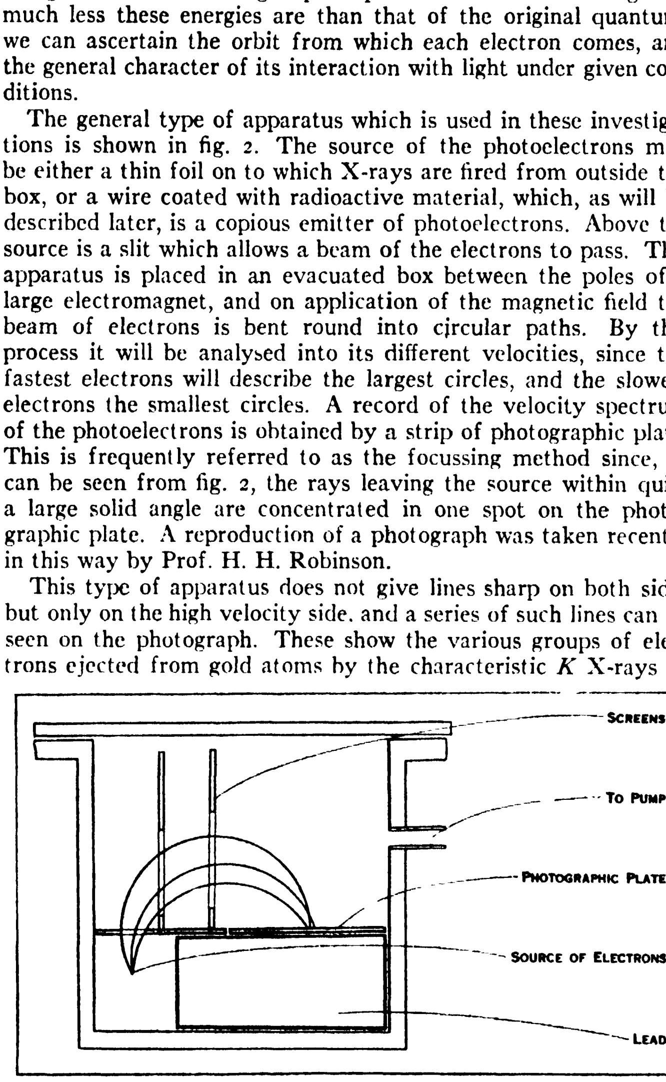


FIG 2.—FOCUSSING METHOD OF ANALYSING COMPLEX BEAM OF ELECTRONS BY REFLECTION IN UNIFORM MAGNETIC FIELD

copper (Cu K_α). On the original photograph it is possible to distinguish no less than 13 groups, some of which are partially superimposed. All of these are due to the absorption of the same frequency radiation, and the difference in the energies of the groups is due to the multiplicity of the electron levels in gold.

This method was first tried by Robinson and Rawlinson in 1913, and owes its development largely to M. de Broglie. Since the frequency of the X-rays used is known from crystal measurements, and the energies of the electron groups can easily be ascertained from the geometry of the apparatus and the value of the

magnetic field, it has been possible to verify Einstein's law with considerable accuracy. The accurate measurements carried out by Robinson have confirmed the truth of this equation to be at least one part in 300. It should, however, be emphasized that the importance of the method is that it provides an admirable means of investigating the electron levels in the atom, and from the intensity of the photographic traces it is possible to estimate the probability of absorption of the radiation by each of the separate levels.

Instead of using X-rays generated in the usual way, it is possible to employ the natural X-rays or γ-rays emitted by radioactive bodies during their disintegration. These are similar to X-rays, only in most cases the frequencies, and therefore the energy of the quantum, are much higher. It was by obtaining photographs by the use of these rays that it was first possible to demonstrate that the γ-rays were sharply monochromatic, and constituted a true characteristic spectrum of the nucleus. This method is particularly interesting in this connection since it forms the only practicable way of measuring the wave-length of γ-rays. The ordinary crystal methods of measuring the wave-length of X-rays are difficult to apply as the wave-length is so short, and before the photoelectric effect was understood only estimates could be made. By investigating the photoelectrons ejected from various metals by the γ-rays, Ellis was able to ascertain the particular portion of the atom from which the electrons were being emitted, and then a simple measurement of their energies, coupled with our X-ray knowledge of the atom, immediately yielded the $h\nu$ of the γ-rays.

An entirely different method of investigation is rendered possible by C. T. R. Wilson's cloud track apparatus in which, by a sudden expansion, moist air enclosed in a suitable chamber is put in a condition of supersaturation. The degree of supersaturation is so chosen that in the absence of any nuclei no condensation occurs. Immediately after the expansion a flash of X-rays is allowed to pass through the chamber, and condensation occurs on the ions that are formed. If suitably illuminated these water drops can be photographed. The X-ray beam was limited to a narrow pencil down the centre of the chamber and five separate photoelectrons were visible. Each of the tracks of these photoelectrons shows the history of a separate absorption of a quantum of energy $h\nu$ by the atom located at the head of the track.

The electrons are ejected with such a high velocity that they can penetrate a considerable distance through the gas. Their path is marked by the ions they form in their passage. In the case of electrons formed by X-rays of lower frequency the speed of ejection is less. This is shown in photographs which reveal the greater tortuosity of the paths and the greater density of the water drops along a track.

The Compound Photoelectric Effect.—This is differentiated from the ordinary photoelectric effect of X-rays by the fact that the absorption of the radiation by an atom leads to the ejection of two electrons, and not one as in the other case. Its existence, although previously suspected, was first clearly demonstrated by P. Auger using the Wilson cloud track chamber method. The gas in the chamber through which the X-rays passed consisted of a small percentage of a heavy gas, such as argon, mixed with hydrogen. The argon is found to be responsible for almost the entire X-ray absorption and the small stopping power of hydrogen allowed the ejected electrons to traverse reasonably large distances and give good tracks.

It might be thought that the double tracks of the photograph only show a normal photoelectric effect by two atoms so close together that the tracks appear to start from the same point, but these double tracks occur far more frequently than would be expected on a probability basis, and it is simplest to consider them to come from one atom by some slight modification of the usual process. It will be seen that the further facts support this hypothesis. If a series of such photographs are taken under exactly the same conditions, with the one exception that the voltage on the X-rays (*i.e.*, the frequency of the X-rays) is increased, it is then found that, while one member of a pair of tracks increases in length as predicted by Einstein's equation, the other shows no change. This must not be taken to show an exception to Einstein's equation but rather that this second track is due to some process in the atom, admittedly excited by the primary radiation, but yet not directly depending on its frequency. The first action of the radiation is to eject an electron from the atom in the normal photoelectric way, and the second track occurs because the atom is left in what is called an "excited state" that is capable of further changes.

In the article Atom it is explained how for numerous purposes we can picture the electrons in the atom arranged in a series of shells or groups, each characterized by a definite energy. The process of radiation is held to be due to the removal of an electron from an inner group and the subsequent filling up of the gap by one of the electrons previously in an outer group. Now in the compound photoelectric effect the primary effect of the X-rays is to remove an electron from one of the groups of an argon atom, and in the majority of cases this will be from the innermost or K group. The argon atom is now said to be excited in the K group, and a subsequent transition of one of the outer electrons into this vacant place will lead to the emission of one quantum of the argon K radiation. Sometimes this radiation escapes from the atom, but it may be internally absorbed and never escape at all. In this case the argon atom will emit a second photoelectron whose energy, and therefore length of track in the gas, is determined by the frequency of the argon K radiation and not by that of the incident X-radiation. It will, therefore, not change when the frequency of the incident X-rays is changed. It is possible to secure a second and even a third repetition of this interesting process thereby giving rise to the emission of three or four photoelectrons from one atom.

This phenomenon has been described as if an excited atom always emitted its surplus energy first in the form of radiation, but that, on occasion, this could be subsequently reabsorbed in the same atom. It is held by many authorities that it is rather artificial to imagine radiation to be emitted, apparently to exist independently of the atom, and then to be reabsorbed all inside the minute volume of the atom. It is maintained that it is simpler to state at once that an excited atom, that is an atom with greater energy than the normal, has at its disposal two distinct methods of getting rid of its extra energy, either by emitting a quantum of radiation, or by emitting an electron. There is no doubt that this is a difficult point, but a somewhat similar phenomenon occurs among the radioactive bodies, when, in the opinion of the writer, the evidence is strongly in favour of a true internal absorption of radiation.

The phenomenon of radioactivity is due to a disintegration of the central positively charged nucleus around which are the electrons forming the rest of the atom. Frequently accompanying the actual disintegration, which involves the emission of a material particle from the nucleus, either the α- or β-particle, there is also an emission from the nucleus of very high frequency radiation called the γ-rays. These are of the same type as X-rays, but of higher frequency. These γ-rays are quite frequently absorbed in the parent atom in their passage out from the nucleus through the electronic system, and give rise to high speed photoelectrons. As some radioactive bodies emit a considerable number of different frequencies, each of which can be converted in either the K, L, M, N, etc. levels, it will be seen that a great number of photoelectric groups are possible. These may be investigated by the magnetic spectrum method, previously described in the case of X-rays, and illustrated by fig. 2. In this case, however, since the radioactive body is at one and the same time both the source of radiation and of the photoelectrons, it is merely necessary to place a wire coated with the radioactive material underneath the slit to obtain results.

The radioactive body used was Radium B, and the radiations have an average frequency corresponding to about 300,000 volts. The great complexity of the spectrum may be seen from this reproduction which only shows a part of the spectrum; to obtain all of it different magnetic fields would have to be used. The sharpness and narrowness of the lines is noteworthy. The reason for this is that, in this γ-ray case, all the photoelectrons are due

to this internal absorption in the parent radioactive atom, and, since the radioactive material only forms the thinnest imaginable layer on the surface of the wire, all the electrons emerge with their full velocity. In the X-ray case, when there is external absorption, photoelectrons are emitted throughout the body of the source, and, while those coming from the surface will have the greatest energy and will form the sharp edge of the line, those liberated inside the material can also get out, but will lose a portion of their energy in the process. They thus hit the photographic plate nearer the source and produce a long tail to the line.

This case of internal absorption is to some extent analogous to the compound photoelectric effect with X-rays, and here there is evidence that we may regard the γ-ray in all cases to be emitted but sometimes to be reabsorbed. On the one hand is the entire lack of any evidence of any other form of interaction between the nucleus and the electronic structures, which makes it doubtful to assume it in this case. On the other hand it has been shown by Ellis and Wooster that this internal absorption appears to obey exactly the same relations as those found for normal external absorption. If this view be substantiated by future work, we have here an extremely interesting example of a photoelectric effect all occurring within the minute volume of an atom.

The Direction of Emission of the Photoelectron.—A matter of great interest is to ascertain how the initial direction of emission of the electron is associated with the direction of the electric force in the radiation. It is well established that radiation is some type of electro-magnetic disturbance propagated through space in which electric and magnetic forces at right-angles are associated, both also being at right-angles to the direction of propagation. (*See* ELECTRICITY.) It is to be anticipated that it is the electric force which acts directly on the electron and wrests it from the atom, so that we should expect the electrons to have at least a large component of this motion in the direction of the electric force. The effect of the magnetic force on the electron, when once it is in motion, will be to throw it slightly forward. However, it is scarcely to be anticipated that all the electrons will come out at exactly the same angle to the electric force, since there are many subsidiary effects which will tend to introduce variations and produce a distribution over a range of angles instead of one unique direction.

This phenomenon is most easily studied in the case of the photoelectrons liberated by X-rays and γ-rays, when the velocities are considerable and the electrons have sufficient energy to penetrate several centimetres of a gas. The most fruitful method of investigation is by the Wilson cloud track method, which has already been referred to. If a thin pencil of unpolarized X-rays is sent through a Wilson chamber and the tracks photographed, we can determine at once what is called the longitudinal distribution. The exact direction of the electric vector is always changing, but of necessity it must be always at right-angles to the direction of propagation. If the cloud tracks are photographed with a stereoscope camera we can count the fraction of electrons which are emitted with their directions initially within say 5° of the direction of propagation, between 5° and 10°, and so on, obtaining in this way a distribution curve. The general results are as would be anticipated. Very few electrons travel near the direction of propagation either forward or backwards, the greater number tending to go off more at right-angles in the direction of the electric vector. The distribution curve therefore shows a marked maximum for directions at right-angles to the direction of propagation.

However this is not all, there is a small subsidiary effect which seems to be of great importance. This maximum of the distribution curve is not exactly at right-angles to the direction of propagation, it is shifted a few degrees forward, so that rather more electrons go forward than go back. This becomes more pronounced as the wave-length gets shorter. While for light and soft X-rays it is not to be detected, it may amount to 10°, 20° or 30° for hard X-rays or γ-rays. The primary cause of this asymmetry is to be found in the magnetic forces in the wave-front, but a simple description can also be given on the light-quantum picture. Imagine a quantum of energy $h\nu$ impinging on an electron, being absorbed, and communicating all its energy to the electron. This quantum is not only characterized by its energy, it will also have momentum of amount $h\nu/c$. If we assume that the other causes responsible for the distribution would only produce a symmetrical spread about the direction of the electric vector, we can say that owing to the momentum of the quantum there should finally be an average forward momentum of amount $h\nu/c$. This does shift the maximum forward by about the right amount; but according to some new measurements by Williams there is not exact agreement—the predicted shift is not large enough. Either some other cause is at work or the electrons in the atom, which are moving forward at the instant the wave passes over them, have a preferential chance of absorbing. This is an interesting point and seems likely to shed fresh light on the details of the interaction of radiation and matter.

Another type of asymmetry has also been investigated. By suitable arrangements a beam of polarized X-rays can be obtained. Suppose this is travelling along the direction of x, and the electric vector in the polarized beam is parallel to the y axis. By taking Wilson cloud photographs close to the direction of the x-axis we can now find how the photoelectrons are distributed in the yz plane. As before a distribution is found, but this time, as would be expected, it is symmetrical. The maximum number occurs parallel to the electric vector and there appear to be very few indeed which come off at right angles to this.

Number of Photoelectrons Ejected.—The discussion so far given has centred round the elementary process of the conversion of a quantum and liberation of a photoelectron, and this process has been shown to be described completely by Einstein's equation. Thus, having treated what happens when a quantum is absorbed, the question now arises how often quanta are absorbed It is the essential peculiarity of the photoelectric effect that these two points can be separated so completely, the energy of the ejected electron depending only on the frequency and being entirely independent of the intensity of the radiation, whereas the number of electrons ejected is directly proportional to the intensity.

In considering the number of photoelectrons set free it is simplest to go at once to the conception of an absorption coefficient. Suppose I ergs per sec. are incident upon each square centimetre of a very thin slab of matter, of thickness δx, then the number δn of photoelectrons set free per second will be

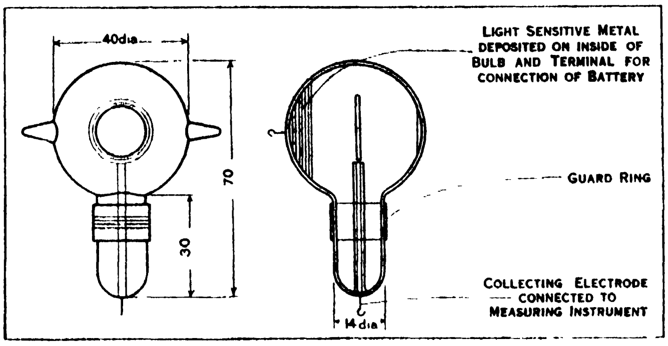
$$\delta n = \mu \frac{I}{h\nu} \cdot \delta x,$$

where μ is called the absorption coefficient and is a characteristic constant of the material and of the frequency of the radiation. If this is applied to a gas it will give exactly the number of tracks that would be observed by a Wilson cloud apparatus In the case of a solid it is usually rather complicated to deduce the actual number of electrons that emerge, since the scattering and absorption of the electrons liberated inside the solid are difficult to follow in detail

It is simplest to consider first the case of the X-rays and γ-rays, and afterwards the absorption effect of one particular set of electrons in the atom, say the K or L electrons. The total absorption of the material is then obtained by adding together the absorption of all the different sets of electrons in the atom. The first point to notice is that absorption, for example by the K electrons of tin, does not start until the frequency is increased to a certain limit. This limit which is characteristic for tin is determined by the condition that the $h\nu$ of the radiation shall be just equal to the work necessary to remove a K electron to the surface of the atom; *i e*, absorption commences with the production of photoelectrons of zero energy From this point onwards, when the absorption is a maximum, it decreases steadily at first about as ν^{-3}, and later, in the γ-ray region, rather less rapidly. The attempt to extend these results towards the region of visible light meets with considerable experimental difficulties, but recently approximate values for the absorption by potassium vapour in the near ultra-violet have been obtained, which may be considered as the extension of the preceding results.

The number of electrons ejected by light engaged the attention

of the early experimenters from rather a different aspect. The experiments were usually carried out with reflecting surfaces of the alkali metals, and an interesting dependence of the number of photoelectrons on the state of polarization of the light was observed. If the light was incident obliquely and was so polarized that the electric vector had a component perpendicular to the surface, the number of electrons ejected was found to be greater



BY COURTESY OF THE CAMBRIDGE INSTRUMENT CO

FIG. 3.—PHOTOELECTRIC CELL

than if the electric vector lay wholly in the surface This phenomenon was investigated in great detail by Pohl and Pringsheim, who found the variation of the emission with change of wave-length of the light when compared on the basis of equal amounts of incident energy. When the electric vector had a component perpendicular to the surface they found a maximum occurred at a certain wave-length, which was not present with the other type of polarization. This led them to effect a division of the whole effect into a normal and a selective effect, the latter showing the maximum.

The important bearing of this subject on the nature of light depends entirely on the surprising fact, expressed by Einstein's equation, that the velocity of the ejected electron is determined only by the frequency of the radiation, and is independent of the intensity of the radiation. This is entirely contrary to what we should expect from a wave motion, yet the phenomena of interference, and in fact the whole of ordinary optics, appear to show indubitably that radiation is a wave motion. This will be apparent if we imagine first a metal plate placed so close to an X-ray tube that the radiation is pouring on to it, and then removed so far away that the radiation is even difficult to detect. On the wave picture one would say that, in the second case, the electric vector in the radiation hitting the plate was very much weaker than in the first, and we would expect that not only would the number of electrons be less but also that the electric vector would be able to transfer much less energy to the electrons, and they would come out with much lower energies

Whilst the number of electrons is certainly less in strict proportionality to the intensity, the energy of the individual electrons will be the same in both cases. Weak or intense radiation, as long as the frequency remains constant, always gives the same energy to the electrons. This result is quite incompatible with our ordinary ideas of a wave motion, and the simplest way of expressing this is to notice how the alternative picture of light quanta explains the dilemma. If, instead of imagining the radiation to spread out from the source in waves, we imagine the energy to be emitted in bundles or quanta of magnitude $h\nu$ then with intense radiation there will admittedly be more quanta traversing a body, but even with weak radiation the few quanta which do arrive are still the same. They will naturally lead to the ejection of fewer electrons, but when a quantum is absorbed it always involves the transference of the same amount of energy, and the photoelectron will have the same energy as if the density of quanta were far greater. Great difficulties are raised by any attempt to explain interference by a light-quantum picture and the problem of reconciling these two different views has at present not been solved. A fuller discussion will be found in the articles QUANTUM THEORY and ATOM, where it is pointed out that probably both views are correct The point is that, if we insist on describing atomic processes in language and concepts used for large-scale phenomena, then inevitably a duality will appear. Radiation must sometimes be pictured as waves, sometimes as particles. How far-reaching is this duality may be seen in the fact that electrons, and other material particles also, behave sometimes in a manner only explicable on a wave basis.

Photoelectric Cells.—The practical application of photoelectricity to measuring light intensities is made by means of the photoelectric cell. In its simplest form this consists of a glass bulb silvered internally, and on this inner coating is deposited a very thin layer of some metal such as potassium. In the centre of the bulb is arranged a collecting electrode supported on a wire sealed directly through the glass, and metallic connection is made to the potassium in the same way. A diagram of such a cell is shown in fig. 3. The cell is sometimes suitably mounted in a light-tight wooden box. The silver is removed from a certain area of the glass so as to allow light to enter into the cell. The collecting electrode is seen at the bottom of fig. 3.

The whole apparatus can truly be described as a photoelectric cell, since, when light enters the bulb, electrons will be ejected from the potassium, which will charge up positively, and will be collected by the central electrode rendering the latter negative. To measure light intensities precautions must be taken to collect the whole of the electron stream liberated, since it is the number of electrons which is directly proportional to the intensity of the light. The method of doing this is to apply a negative potential to the potassium surface as shown in fig. 4, the collecting electrode being practically at the potential of the other end of the battery by connection through the measuring instrument. For considerable intensities of light this may be a sensitive galvanometer, but in most cases some type of electrometer, such as an ordinary quadrant electrometer or the special quick period quadrant designed by Prof. Lindemann, is preferable. The most sensitive arrangement is to measure the rate at which the electrometer charges up, *i e*, the rate at which the needle moves, but when it is possible the constant deflection method is far more convenient It will be noted that while one terminal of the electrometer is connected directly to the collecting electrode, the other is connected to earth, and the constant deflection method consists in connecting a very high resistance, of the order of 10 to 10,000 megohms, across the electrometer. The latter then measures the potential drop across this resistance due to the current through the photoelectric cell. An important precaution is to have a guard ring (*see* fig. 3), consisting of a ring of metal or silvering, in the position shown, and to connect this to earth. This prevents charge creeping over the surface of the glass from the high potential electrode to the measuring instrument. The general working of the cell is rendered far more regular by taking precautions

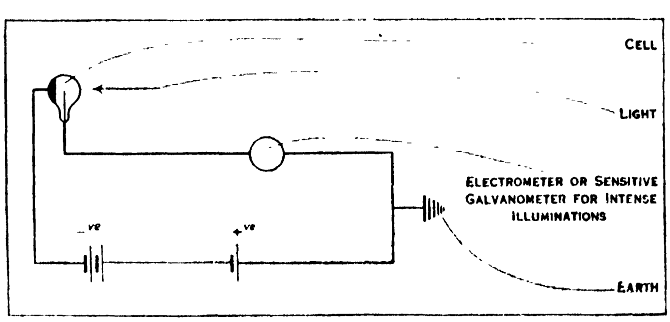


FIG. 4.—METHOD OF USING A PHOTOELECTRIC CELL

to keep it in a dry atmosphere, as a film of moisture on the surface of the glass renders it virtually a conductor.

While a photoelectric cell constructed in this way gives a qualitative measure of the light entering it, it is certainly somewhat insensitive, and great improvements have been effected by attention to two points. The first is the correct preparation of the light-sensitive surface—potassium in the case already described. It appears that the sensitivity can be greatly improved by the following process. The potassium is carefully purified by distillation, and is finally deposited by the same process inside the

cell. A little oxygen is then admitted, and a glow discharge passed for a few moments. The oxygen is then pumped out and the potassium is left in a very sensitive colloidal state. The second improvement is to admit a small amount of helium into the cell instead of leaving it completely evacuated. The electrons leaving the potassium surface and accelerated by the applied potential now cause ionization by collision, and a greatly increased current is obtained. The one objection is that the current now depends on the applied potential, as can be seen from fig. 5. It is usually safe to apply a potential of 200 volts, and at this point a change of 1 volt produces a change of about 1% in the current.

FIG. 5.—CURVE SHOWING HOW THE CURRENT GIVEN BY A GAS-FILLED PHOTOELECTRIC CELL DEPENDS ON APPLIED VOLTAGE

A matter of great practical importance in the use of photoelectric cells is that they are not equally sensitive to all wave-lengths. This can be seen from fig. 6, which shows in arbitrary units the photoelectric effects in potassium, rubidium and caesium cells for equal amounts of incident energy of different wave-lengths. The vertical scale is arbitrary in each case, and the curves do not show the relative sensitivities of the three types of cell. The ratio of the total sensitivities of potassium, rubidium and caesium cells as here constructed is about as 4:2:1, but the relative sensitivity for any particular colour depends on the wave-length; *e.g.*, for light of 6,000 Å.U., the order would be reversed, the caesium cell being most sensitive. A sodium cell can often be used with advantage for light of a shorter wave-length since its maximum occurs at about 3,400 Å.U. For ultra-violet work the envelope is usually of quartz, as glass begins to absorb strongly. It will be realized from these examples that a photoelectric cell cannot be used for comparing directly the intensities of two beams of light unless they are of the same colour, or, more accurately, of the same spectral distribution.

FIG. 6.—CURVES SHOWING HOW THE PHOTOELECTRIC CURRENT, IN POTASSIUM, RUBIDIUM AND CAESIUM CELLS VARIES WITH THE WAVE-LENGTH OF THE LIGHT (THE 3 CURVES ARE INDEPENDENT)

The uses of photoelectric cells are so manifold that a catalogue of them would be monotonous. Briefly they replace the human eye whenever quantitative measurements are needed; *e.g.*, they are frequently used to measure or compare the light arriving at the earth from stars; also, many photometers (*see* PHOTOMETRY) depend on their use. The density of a photographic plate may be found either by measuring the diminution in intensity of a beam of light passing through it, or alternatively may be put equal to the density of some standard plate when each produce the same weakening of the beam. In either case the essential is to have a quantitative measure of the intensity of a light beam, and for this purpose photoelectric cells are usually used.

PHOTO-ENGRAVING. A photo-mechanical process of making relief printing blocks in line and half-tone. The term "process engraving" is frequently used in Great Britain and covers the preparation of planographic and intaglio printing surfaces as well as the making of blocks for printing by typographic methods.

It is a strange coincidence that the history of the printing art—the art which secures records of the past and future progress and development of other arts and crafts—cannot record with any degree of accuracy its own inception, which fact also applies to photo-engraving, the most recent addition to the crafts included in the printing industry. The first etched line blocks were made by Gillot, a Parisian lithographer, in 1859, when he took impressions in a special ink from designs drawn on lithographic stones. These he transferred to a zinc plate, and, with an acid resisting ink, rolled up the design, placing the plate in a mordant which etched away the bare metal, leaving the parts protected by the ink standing in relief, and to him is ascribed the development of line blocks. By the same method, transfers from designs engraved or etched into plates (intaglio), wood-cuts, type or drawings made on transfer paper or drawn direct on to a zinc plate, may also be made into printing blocks. At the Paris Exhibition in 1867 Gillot received an award for his work, but it was not until photography was applied to the reproduction of illustrations that the fullest benefits of this speedy method of making printing blocks was reached. By photography an artist's drawing can be reduced or enlarged in proportion, a negative from the original drawing being made to the size required, and photographically printed on to the zinc plate, previously coated with a light sensitive solution. The photographic method was first employed in 1872 by the son of Gillot, and the development of this direct method of reproducing the original drawing soon caused the demise of the wood-cut.

The invention of the half-tone process has given rise to long and heated controversy between present-day authorities as to who first reproduced photographs and paintings by this method. The difference of opinion, however, is largely due to a technical definition of the word, "half-tone," and the particular method whereby the tones of an original picture were "broken up" in order that it may be printed. In early experiments various methods were employed to achieve the end desired. Sometimes a negative was made by photographing through a piece of gauze, or, photographic prints of lines were made on a negative. It is not known who first employed the cross-line screen. The method now used is probably the outcome of experiments conducted by a number of people.

Fox Talbot, of England, in 1852 suggested the "breaking up" of the tones of a photograph by means of a screen of ruled opaque lines, muslin, crêpe or gauze, and from that date experimenters in various parts of the world have been working on these lines, applying their own particular methods. The successful working of the process depends upon the use of a screen by which the tones of the original are represented on the photographic plate by means of "grain" or "dots" of varying sizes. In New York in 1875 W A. Leggo and his brother, Canadian lithographers, ruled lines on a piece of glass through blackened collodion films, sealing two of these (face together) with Canada Balsam; George Meisenbach, of Munich, patented a process in 1882, and to him is generally credited the invention of the half-tone process, he being the first to put the process to practical use; while Frederick Ives, an American, was producing satisfactory work in 1886 by the use of a sealed cross-line screen; and he, probably, is the "father" of the method which is now in common use. The Leggos' method, of making ruled screen, was improved upon by Louis Edward Levy in 1891. In this instance the lines were etched into glass and filled with a thick black pigment. Louis Levy and his brother Max were endeavouring to make cross-line screens in 1883.

The invention and development of this process, however, can probably be summed up by stating that Fox Talbot in England anticipated the half-tone process in 1852, although workers in other countries were working on similar lines, but it was not until the Meisenbach method was used that the process left its experimental stage. The characteristic of the latter method was to reproduce a picture represented by "dots," to achieve this Meisenbach used a single line screen which was turned round during the exposure. His process was introduced into England in 1882, and the printing plates made were commonly known as "Meisenbach Process Blocks."

THE MAKING OF BLOCKS

In making any type of block, if the reproduction of an original rawing is to be successful, attention must be given to every age of the work; the character of the drawing should be nsidered in relation to the special method by which it is to be produced. Originals in line, where light and shade are obtained varying thicknesses of the line, are reproduced by a line block. or this purpose the drawing is made in pen and ink, each line which must be solid and opaque, *i.e.*, the effect must not be tained by grey lines or "washes" but each line must be solidly awn in black ink.

Photographs, wash drawings and paintings are reproduced by alf-tone, *i.e.*, the tones of the original are reproduced by reticulting the subject by means of a screen which may be either grain cross-lined. When photographs, especially of a technical character, are to be reproduced, it is essential that "retouching" of the iginal be resorted to; this is of a highly specialized character, necessitating the emphasising of the parts which are to be specially rought out, throwing back the details which are not of such importance, and, not infrequently, eliminating the surroundings. This done by artists who use pencil, ink, and frequently, aerograph raying in the preparation of an original for reproduction by hoto-engraving.

The Camera.—A specially constructed camera is used, its ain features being its rigidity and long bellows to allow for enrgement or reduction. The front frame of the camera is firmly cured whilst the back frame containing the focussing ground ass moves in slots which keep it parallel with the front. The mera is supported on a frame on one end of which an upright oard is fixed. On this is placed the original to be reproduced; works in grooves so that it can be moved sideways to obin the correct position. On the front frame of the camera is a ction to which the lens is attached; this slides up and down to low for the centring of the copy. It is necessary that the copyoard and the camera move in perfect unison during exposure, nd precautions have to be taken to obviate movements in opposite directions through vibration.

Special lenses, too, are required, and those known as anastigatic are found best for photo-engraving. On the lens is a slot to which stops or diaphragms of peculiar shapes are inserted nd which act in the same way as the iris or circular apertures sed in ordinary photography. The stops used by photo-engravers ave an important function to perfom, since they determine the hape of the "dots" and influence the final results.

For all methods of direct printing the negative has to be reersed, *i.e.*, left to right. This is done by passing the rays of light rough a glass prism or mirror so that the image is first reected on to the prism and from thence through the lens. Another ethod, frequently used in America, is to make the negative withut the use of a prism and, after developing, strip the film and btain a reverse. This method is not possible, however, when aking negatives for colour printing. The reversing is necessary allow for a positive impression of the design to be printed upon ne paper.

When reproducing colour work there is an attachment whereby colour filters" are fixed to the lens. On the back frame of the mera are slots for carrying the dark slide which contains the hotographic plate. When half-tone plates are to be made the reen is placed in the camera in front of the dark slide.

Illumination.—In photo-engraving, great attention has to be iven to lighting to ensure that the copy is evenly and sufficiently luminated. Whilst daylight is most effective, it is not always ossible to use it, therefore artificial lighting has to be resorted ; the usual procedure is to suspend two arc lamps from supports, ne on each side of the copy-board, these being adjustable to eet the special requirements of the work to be reproduced.

Photographic Plates.—Either wet (collodion) or dry (emulion) plates are used, in certain classes of work the wet plate eing preferred by some photo-engravers.

LINE BLOCKS

When a negative of a line drawing which has to be made into a printing block has been obtained a photographic print from it is placed on to a piece of metal, usually zinc, which is first thoroughly cleaned by polishing with water and powdered pumice, a felt pad being used for the purpose. The plate is treated with a solution of alum and nitric acid and then coated with a solution, sensitive to light, made up of water, albumen, ammonium bichromate and liquid ammonia. The solution is carefully poured over the zinc plate and placed in a whirler which spreads the solution evenly over the surface. This is dried by heat. The negative is then placed film side to the coated zinc plate and put into a printing frame with a plate glass front, a close contact being essential. This is obtained by means of screws or by using a vacuum frame. The negative and coated plate (which are firmly secured in the frame) are then exposed to light (usually electric), the time of exposure varying from two or three minutes to ten minutes according to the quality of the negative and the intensity of the light. The negative and plate are then removed from the frame, and the metal plate, after being slightly warmed, is placed on a flat surface and rolled over with a special ink until it is evenly covered. It is then placed in a tray of clean water and the surface gently rubbed over with cotton wool. The albumen coating, where it has not been hardened by the action of light, is washed away leaving those parts which have become hard and insoluble by exposure to light adhering to the plate. When the clean parts of the zinc are thoroughly cleared, the plate is dried by heat and any defective line retouched, after which the plate is dusted over with a fine powdered resin which sticks to the ink providing a great resistance to the acid with which the plate is to be etched. It is then dusted with a soft hair brush to remove the surplus resin, and subjected to heat which melts the resin, or, as it is commonly called, "dragon's blood," so that it runs slightly down the sides of the lines. When the plate is cool it is ready for etching, *i.e.*, it is placed in a bath made up of two oz. of nitric acid and 60 oz. of water for the first etch; but before doing so the margins and back of the plate have to be coated with a varnish which prevents the acid etching away those parts to be left unetched. Whilst the etching is taking place the mordant is kept in motion. When this is done by hand the baths are rocked so that the solution flows to and fro over the face of the plate, which is brushed during the process to keep the metal clear of oxide; machines, however, are now generally used for this purpose, and the acid is sprayed by means of air on to the surface of the plate. When the plate has been a short time in the bath it is removed, washed and cleaned and lightly wiped over with a sponge containing a weak solution of gum arabic, after which it is rolled up with ink, dried by heat, and another dusting of resin applied in four directions so that each of the four sides of the lines will be protected from the acid which is apt to "underbite" the lines. The plate is again heated, causing the resin in the ink to melt and run down the sides of the etched lines, and the operation has to be repeated several times before the necessary depth is obtained.

The line process is occasionally used for colour work. The colours are generally made up of a number of "solid tints" or "stipple," the usual method being to take "setoffs" from the etched "key plate" and place them on to another piece of zinc, "stopping" out or painting those parts required for the particular colour in which it has to be printed. Where stipple is to be introduced, shading mediums are usually employed. These consist of a sheet of gelatine, with the design of the particular grain, dot, line or stipple, standing in relief. This is rolled over with transfer ink, and placed face downwards on the plate, which has been gummed over on those parts where the "work" is not required, pressure being applied by a roller or squeegee to those parts of the "setoff" from the key plate which have to be printed in the particular ink. Each colour requires a separate plate which is then rolled up, powdered and etched in the usual way.

Half-tone Blocks.—The half-tone engraving is the process by which full-tone subjects in monochrome and colour are reproduced. The negative is made in the usual way, but to provide the necessary reticulated surface the exposure is made through a screen. This may be composed of regular grains (mezzograph),

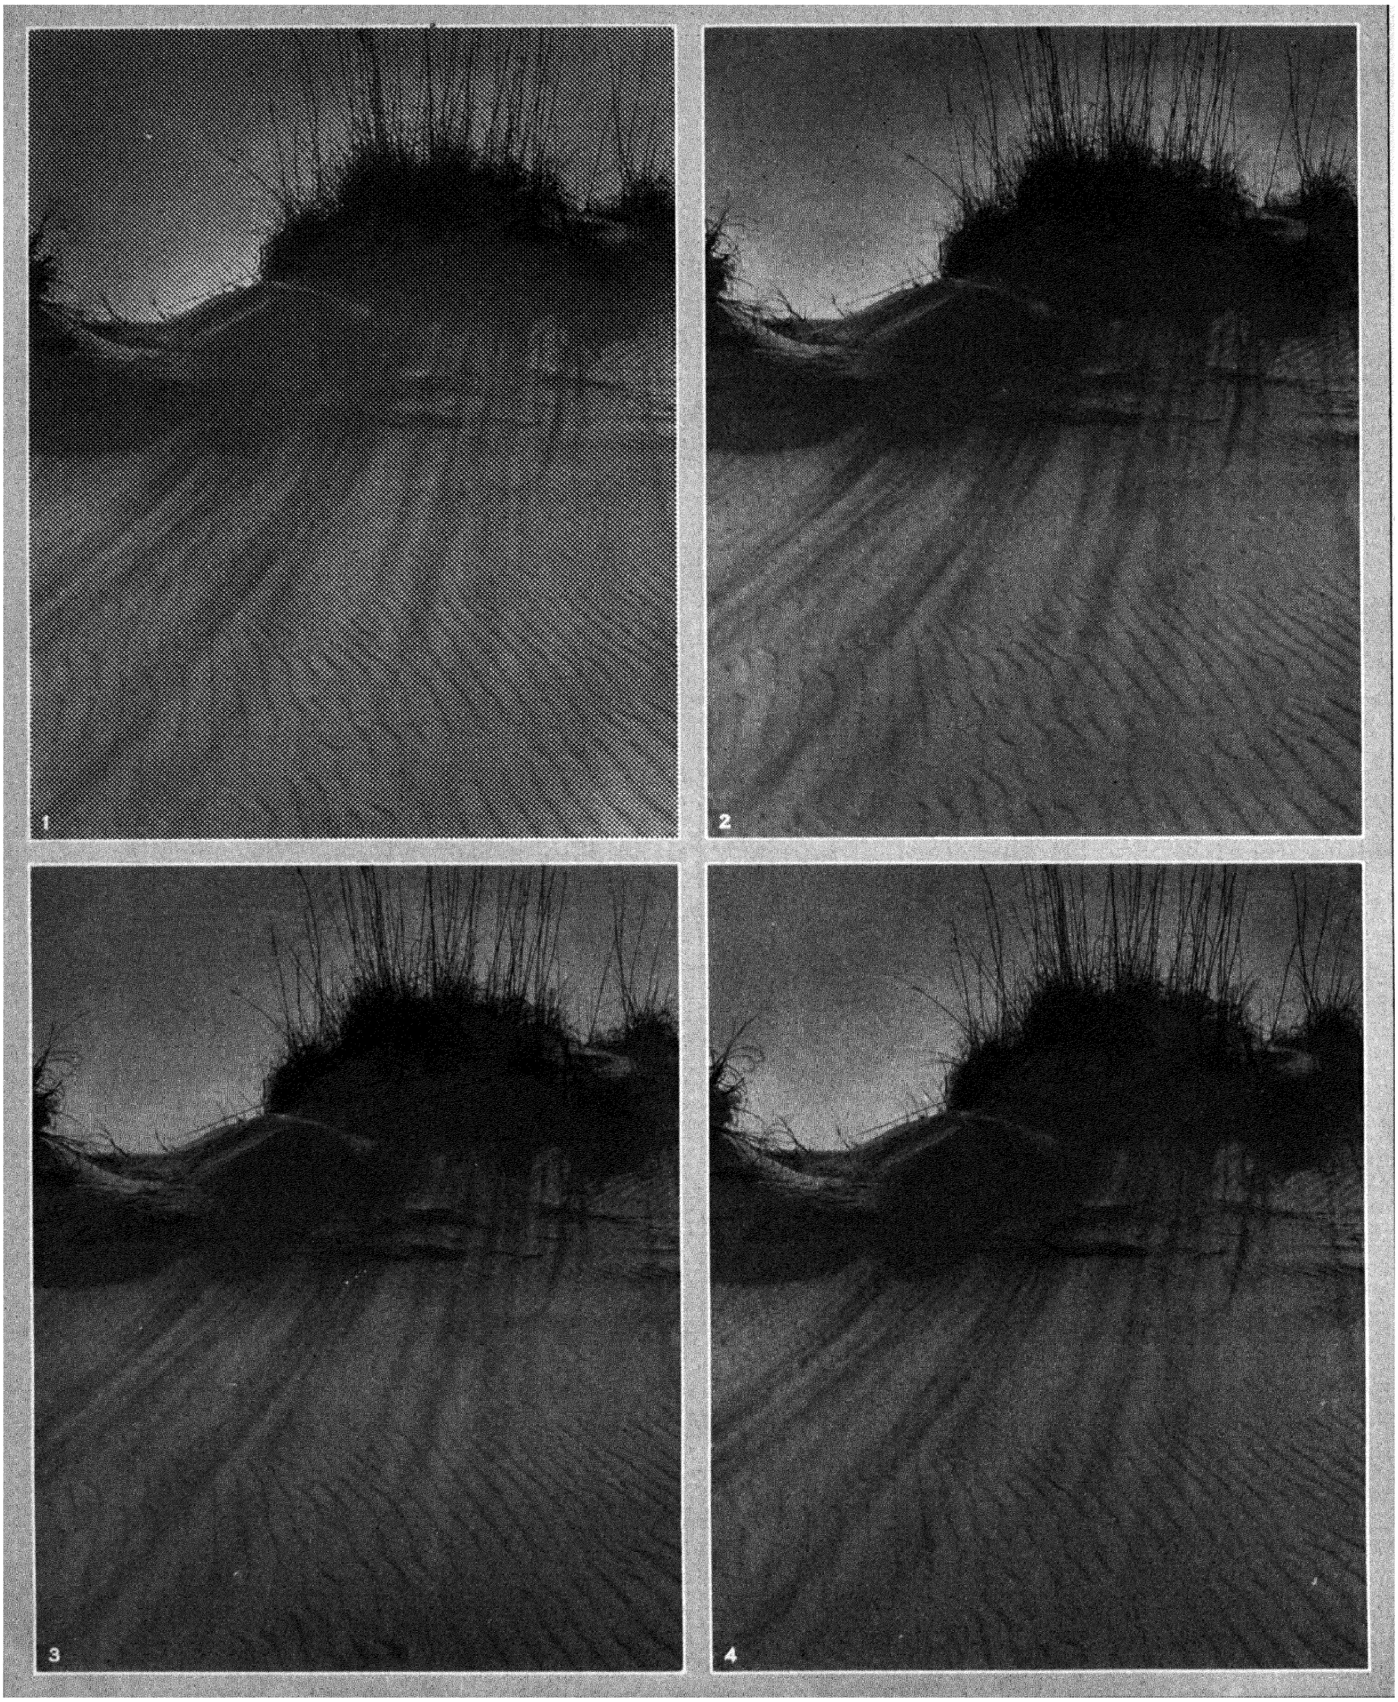
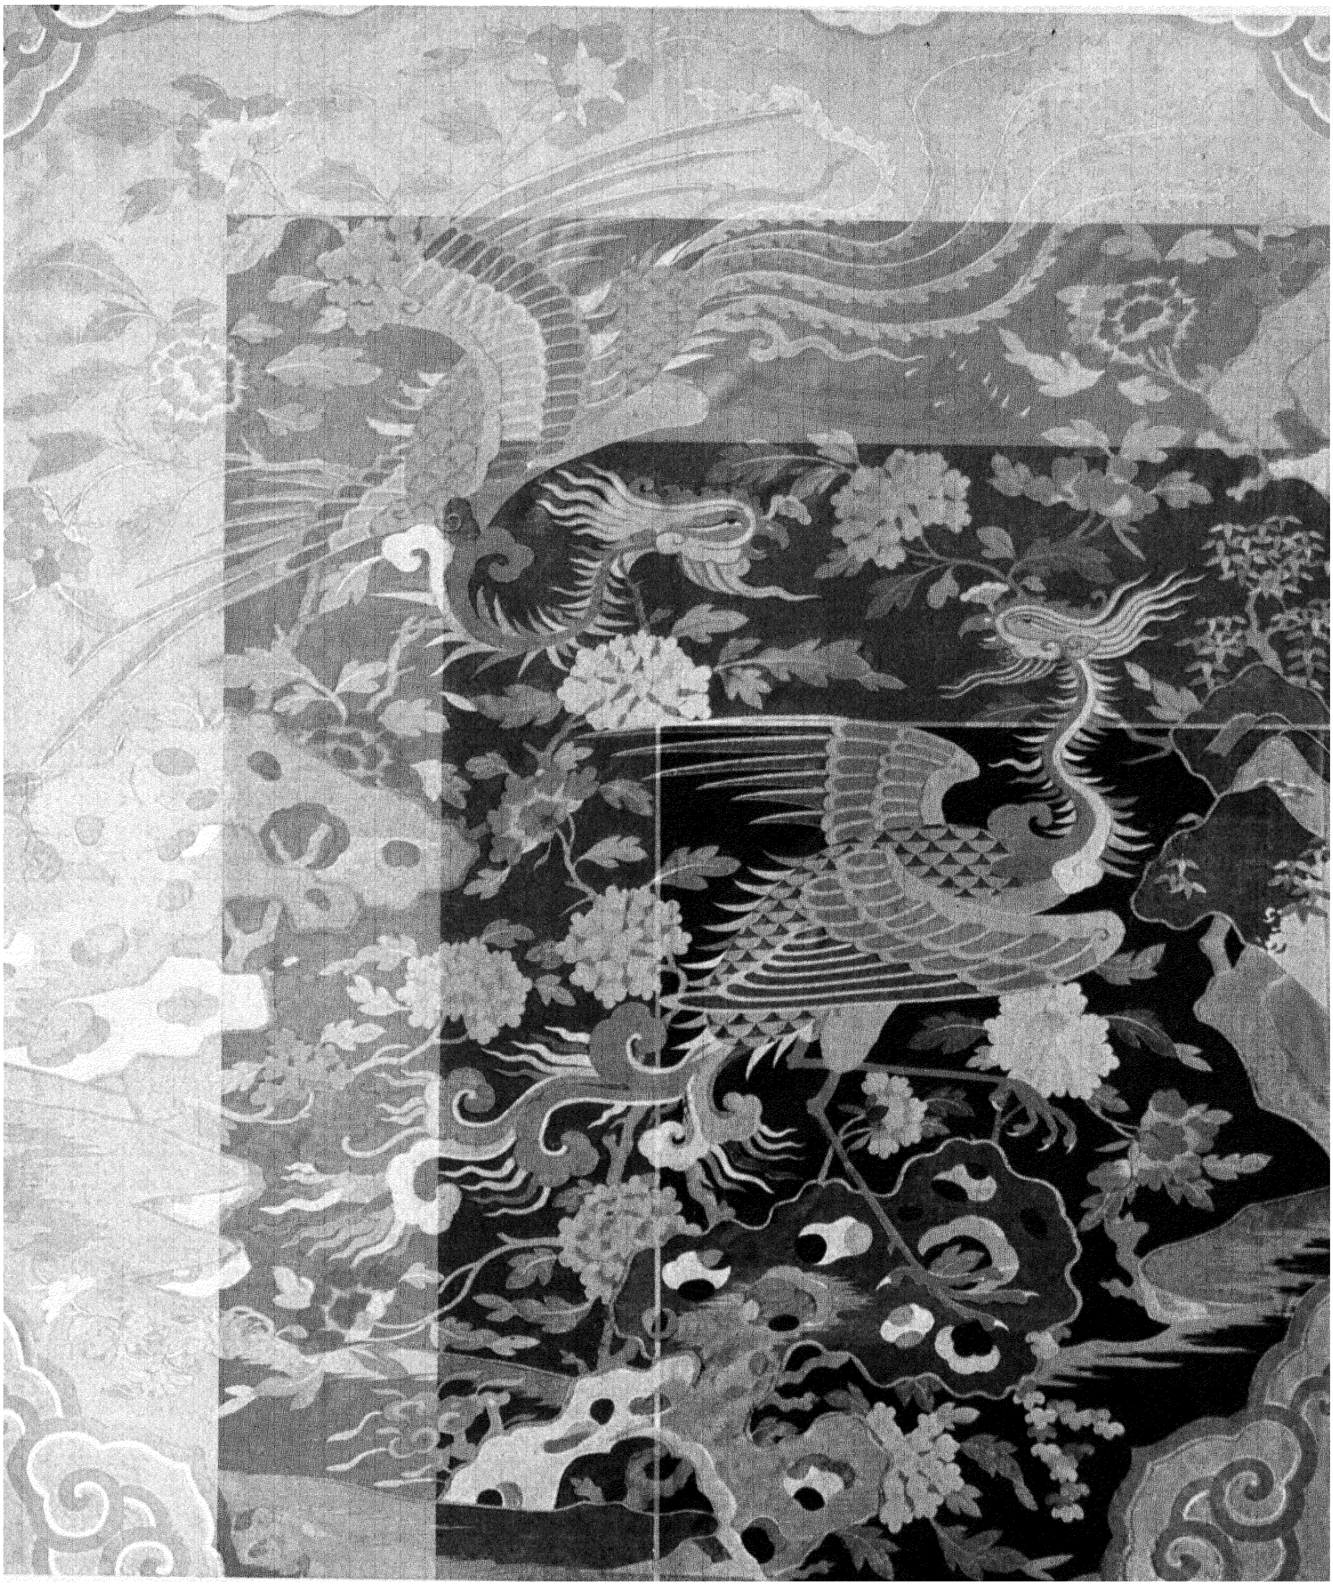
PHOTO-ENGRAVING

1. **Process camera**, showing construction peculiar to this type in which the camera is turned at right angles to frame axis so that image may be turned from left to right by means of prism shown in fig. 3
2. **Etching bath, rocking-tub type**
3. **Lens and prism** used when photographing a subject which has to be printed by **direct method**. The prism reverses the subject so that it appears the "right way" when printed
4. Highly magnified view of **halftone screen**, consisting of two sheets of polished glass on which lines have been ruled diagonally, filled with opaque material and sealed together
5. **Etching machine, splash type**, in which the etching solution is splashed against the plate by means of paddles instead of by rocking as in the tub type
6. **Vacuum printing frame**, so-called because the creation of a vacuum within exerts a uniform pressure on the negative and sensitized metal plate bringing them into close contact before exposure to light



EXAMPLES OF A SUBJECT REPRODUCED BY HALFTONE SCREENS OF DIFFERENT TEXTURES

1. 60 cross-line screen, used when printing on the cheaper grades of paper, such as newspapers and posters
2. 100 cross-line screen, used on machine-finished book paper
3. 133 cross-line screen, used on super-calendared and dull-coated papers
4. 175 cross-line screen, used when reproducing subjects containing fine detail printed on coated paper



THE PROGRESSIVE STEPS IN FOUR-COLOUR PRINTING

The colours used in four-colour printing are: yellow, red, blue and black. The four colours are separated out by photography, by the medium of colour filters, each filter being the complementary to the colour to be separated, viz: Blue violet for yellow printer; green for red printer; orange-red for blue printer and a light yellow for black printer. Photographic prints are made from the four colour negatives on copper plates; after which the copper plates are etched, and when the blocks (one for each colour) are superimposed one upon the other in the printing press the result is a reproduction of the original in all its combination of colour. In the above, from left to right, the large area is an impression from the yellow plate. Next area is the red plate printed upon the yellow. Third is the blue plate printed upon the yellow and red. The smallest area is the black plate printed upon the three colours. Regularly the four plates are all the same size. In the specimen shown here, successively smaller plates were used to illustrate the progressive printings

or, what is most general, a series of lines running across each other at right angles. The cross-line screen consists of two sheets of thin plate glass, ruled with diagonal lines of mechanical exactitude. These are engraved into the glass, each piece of glass being ruled at right angles to the other. The lines are filled with a black pigment, leaving transparent spaces between. The two sheets of glass are placed face to face and sealed, the black lines crossing each other and leaving square transparent openings through which the light passes before it reaches the photographic plate. If a cross-line screen is held up to the light it presents a "lattice work" appearance.

Half-tone screens are made in various "gratings" of rulings. These vary from 60 to 400 lines to the inch, though for half-tone blocks it rarely exceeds 200 lines. The different rulings are used to suit the grade of work to be reproduced and the class of paper on which the illustration is to be printed. When printing on cheap, coarse paper, such as "news," a 60-line screen is usually used. The more open the screen, the more brilliant and great a contrast there is in the reproduction, the easier it is to print. The closer the screen, the greater the detail in reproduction. Blocks made with fine screens require to be printed on a highly finished or coated paper. For ordinary "black and white" commercial work, screens from 120 to 150 are used, and for fine colour reproductions, screens from 150 to 200. The screen is secured in a holder and placed immediately in front of the dark slide holding the photographic plate. The screen distance—an important factor—can be adjusted to suit the particular work in hand. When the exposure is made and the negative developed, it will be found upon examination that the tones in the original are represented by a large number of dots varying in size according to the tones contained in the original.

The next operation is to place photographically a print from the negative on to a metal plate which, for half-tone work, is usually copper. The solution for coating plates for half-tones is different from that used for line work. It is composed of fishglue, ammonium bichromate and liquid ammonia, albumen occasionally being added. The copper plate has to be prepared by removing all grease and foreign matter. It is usual to heat the plate and rub it back and front with caustic potash, finishing off by polishing it with charcoal. The sensitive solution is then poured on the plate and placed in a whirler to distribute the coating evenly. The fishglue solution, or as it is usually termed, "enamel," forms an acid resist. After "printing down," the copper plate is placed in water coloured with an aniline dye, the enamel absorbing the dye. The plate is washed in water, after which the design becomes visible. It is then dried and subjected to heat, or, as it is called, "burnt in," the effect being to increase the resistance of the enamel to the etching fluid. The margins and back of the plate have to be painted with asphalt or shellac varnish to protect those parts from the acid whilst etching. The plate is then ready to be placed in the etching bath, which is made up of a solution of iron perchloride at a strength of about 40° Beaume. The plate is left in the solution for a few minutes and then examined to see if the etching is proceeding evenly over the whole surface.

The etching of the plate is continued until the fine dots in the higher lights are as small as it is possible to etch them, great care being taken that the acid does not underbite the "dots." When the etching of certain parts has reached the stage when it would be dangerous to proceed further, they are "staged," or stopped out with asphalt and varnish and the plate again immersed in the bath. A series of fine etching has then to be undertaken, *i.e.*, stopping out with an acid-resisting varnish those parts which have been etched to their fullest extent, and applying a series of local etchings for the purpose of putting "life" into the plate. This is done by saturating a fine brush with the etch and placing it on the area requiring such treatment. A proof is then pulled from the plate, compared with the original copy, and any necessary alterations made. When passed, the plate is "finished" and mounted on wood ready for the printer.

When a vignetted block is required, the design and close surrounds are protected with varnish and the extreme edges are treated with acid so that the "dots" on the latter are reduced to the smallest point, gradually increasing in size towards the design. In this way, graduated results are obtained until the dots merge into the white paper without showing a sharp edge.

When pencil drawings are to be reproduced, it is usual to make a "high light" negative, *i.e.*, the high lights in the drawing and the paper on which it is made do not show "screen." This is done in the making of the negative, one of two methods being usually followed:—(*a*) *direct*, when an over-exposed negative is made and certain stops used during the exposure which tends to make the "dots" in the high lights overlap and become solid, the other tones being brought back to their correct relation by manipulative development; and (*b*) *the indirect method*, entailing the use of three photographic plates: first, a continuous tone negative is made of the original, which can be retouched; from this a positive is made through a screen; and from the positive a negative is obtained with the "dots" eliminated from the highest lights, which include the paper on which the drawing has been made.

Combined line and half-tone blocks are frequently made for commercial purposes. This can be done either by making two blocks, one in line and the other in half-tone, cutting out the spaces in the line block and inserting half-tone plates which must be made to fit the space; or by making two negatives, one in line and the other in half-tone, stripping the films from the photographic plates and placing them in their respective positions on a piece of glass which constitutes the negative used for printing down on to metal. In this way the combined design is etched on one plate and at one operation.

Colour Work.—When reproducing colour subjects by the half-tone process the blocks are made in the same way as half-tones but the photographic plates must be colour-sensitive (panchromatic); and when making the exposure the light not only passes through the prism, lens and screen but also goes through what are known as "colour filters." These are optically flat coloured pieces of glass held in a frame attached to the lens and as the light passes through the particular filter, only certain rays of light reach the photographic plate. A special colour filter is used for each colour negative. Thus, a negative only records the colour and its component tints of one of the fundamental colours of the spectrum.

To make a negative for the yellow printing plate, a blue filter is used; for the red printing plate, a green filter, and for the blue printing plate, a red filter. The light, passing through the respective filters prevents the colours and tints not complementary to the inks in which the printing blocks are printed being recorded on the special photographic plate.

As in the production of the half-tone plate, the ruled screen is placed in front of the photographic plate, but for colour work, a circular screen, which can be set to different angles, is used for each of the colour negatives. The angles of the screen must be different for each colour to prevent a "pattern" or "moire" effect taking place when the three colours are superimposed in printing. One of the colours has the screen angle at 45° from the vertical, and the others 75° and 15° respectively. The negatives are developed, printed down on to metal and etched in the same way as when making a monochrome half-tone plate, but much fine etching, demanding great skill, has to be done in the production of colour subjects. The "fine etcher" must possess a good knowledge of colour and its analysis so that the final results approximate to the original painting. He has to endeavour to rectify the shortcomings of the means taken to dissect the colours of the original and the inability to obtain photographically a true rendering of the colour values on the negative. This he does by a series of fine etchings, stopping out certain parts and continuing the etching by local application. This operation may have to be repeated a number of times, and many proofs from the plates pulled before the desired results are obtained.

It is now usual to include a fourth colour when reproducing coloured subjects. This is usually printed in a grey or black; the "colour," however, is not dissected in the ordinary sense of the term, although an amber filter is used. The fourth plate represents the whole of the tones in the original in their proper relation

to each other, and becomes the key plate. The fourth printing allows for cleaner and more rapid working on the printing machine and at the same time provides a depth of colour and "quality" which, owing to the scientific shortcomings of the process, it is not always possible to obtain. The plates are finished off in the usual way, mounted on wood and sent to the printer along with a series of colour sheets which show the shades of colour used in the proving.

Half-tone colour negatives are made either by the *direct* or the *indirect* method. In the first instance, each colour negative is made in the same way as an ordinary half-tone negative but the exposure is made through a colour filter in addition to the screen, thus recording on the panchromatic plate one of the fundamental colours and its tints and constituting, when developed, one of the half-tone negatives from which a block will be made to print in a certain coloured ink. The *indirect* method entails the use of three photographic plates for each colour. The first exposure provides a continuous tone colour separation negative. This is obtained by making the exposure through the colour filter. This full tone negative can be retouched to assist in rectifying colour values. From this a positive is made through the screen and the printing down negative made by contact with the positive.

The half-tone process is applied to the preparation of printing surfaces for various methods of reproduction, including plates and cylinders for machine printed photogravure and photo-lithography. The preparation of the negative for the latter is similar to that followed when making half-tone blocks, with the exception that a negative which is to be used for printing by "offset" is not reversed. This is achieved by removing the prism from the lens. Extreme care has to be taken, when making a negative for intaglio and planographic printing, to see that the full range of tones are contained in the negative. It is not possible in these processes to re-etch the plates in the same way as the photo-engraver does when making relief printing blocks. The chief advantage of these methods of printing is that a rough surface paper may be used, and attempts are being made to produce relief printing blocks which will answer the same purpose.

The printing of these special plates may be briefly described as follows: A filler of chromium is electrolytically deposited on a sheet of copper. The chromium-coated plate is floated with a solution of albumen sensitized with ammonium bichromate. A high-light negative (the form of negative usually employed) is placed in contact with the sensitized plate in a pneumatic printing frame and exposed to light. After rolling up with litho ink, the plate is developed by washing in water and then dusted with finely ground bitumen, the ink and the bitumen combining during the subsequent process of burning-in to form an acid resist. The plate is then placed in a dissolving bath, the mordant being hydrochloric acid and glycerine kept at a temperature of 75° F. The action of the bath removes the chromium coating from between the "dots" or lines representing the design, and is continued until the bare copper plate appears, when it is transferred to a saturated solution of potassium cyanide. After a further washing in water, it is placed in a bath wherein silver is electrolytically deposited on the copper portions between the "dots." A sponge saturated with benzol is then used to apply a powder composed of mercury and chalk to the plate; this latter amalgamating with the silver produces ink-rejecting areas, whilst the benzol removes the bitumen resist.

The printing plate therefore consists of a chromium-covered surface which accepts the ink, whilst the spaces between the "dots" or lines comprising the amalgam of silver and mercury repel the ink as the inking rollers pass over the plate. The ink and rollers used for this process contain a small percentage of mercury. It is claimed that Pantone makes possible the printing of half-tone illustrations on any grade or finish of paper, the plates themselves being practically indestructible.

Another method of producing colour work from relief printing blocks to print on a rough surface paper is known as the "Blackmore Tintex Process." The plates for this process are "deep etched" in a special way.

It is probably along these lines that half-tone blocks for typographic printers will be developed. Since most people have a decided objection to a glossy paper, which reflects the light and strains the eyes, this will provide letterpress printers with a means of competing with rotogravure and offset printers in producing prints on a dull and uncoated paper in place of the highly finished coated paper which must be used if the best results are to be obtained from a half-tone block.

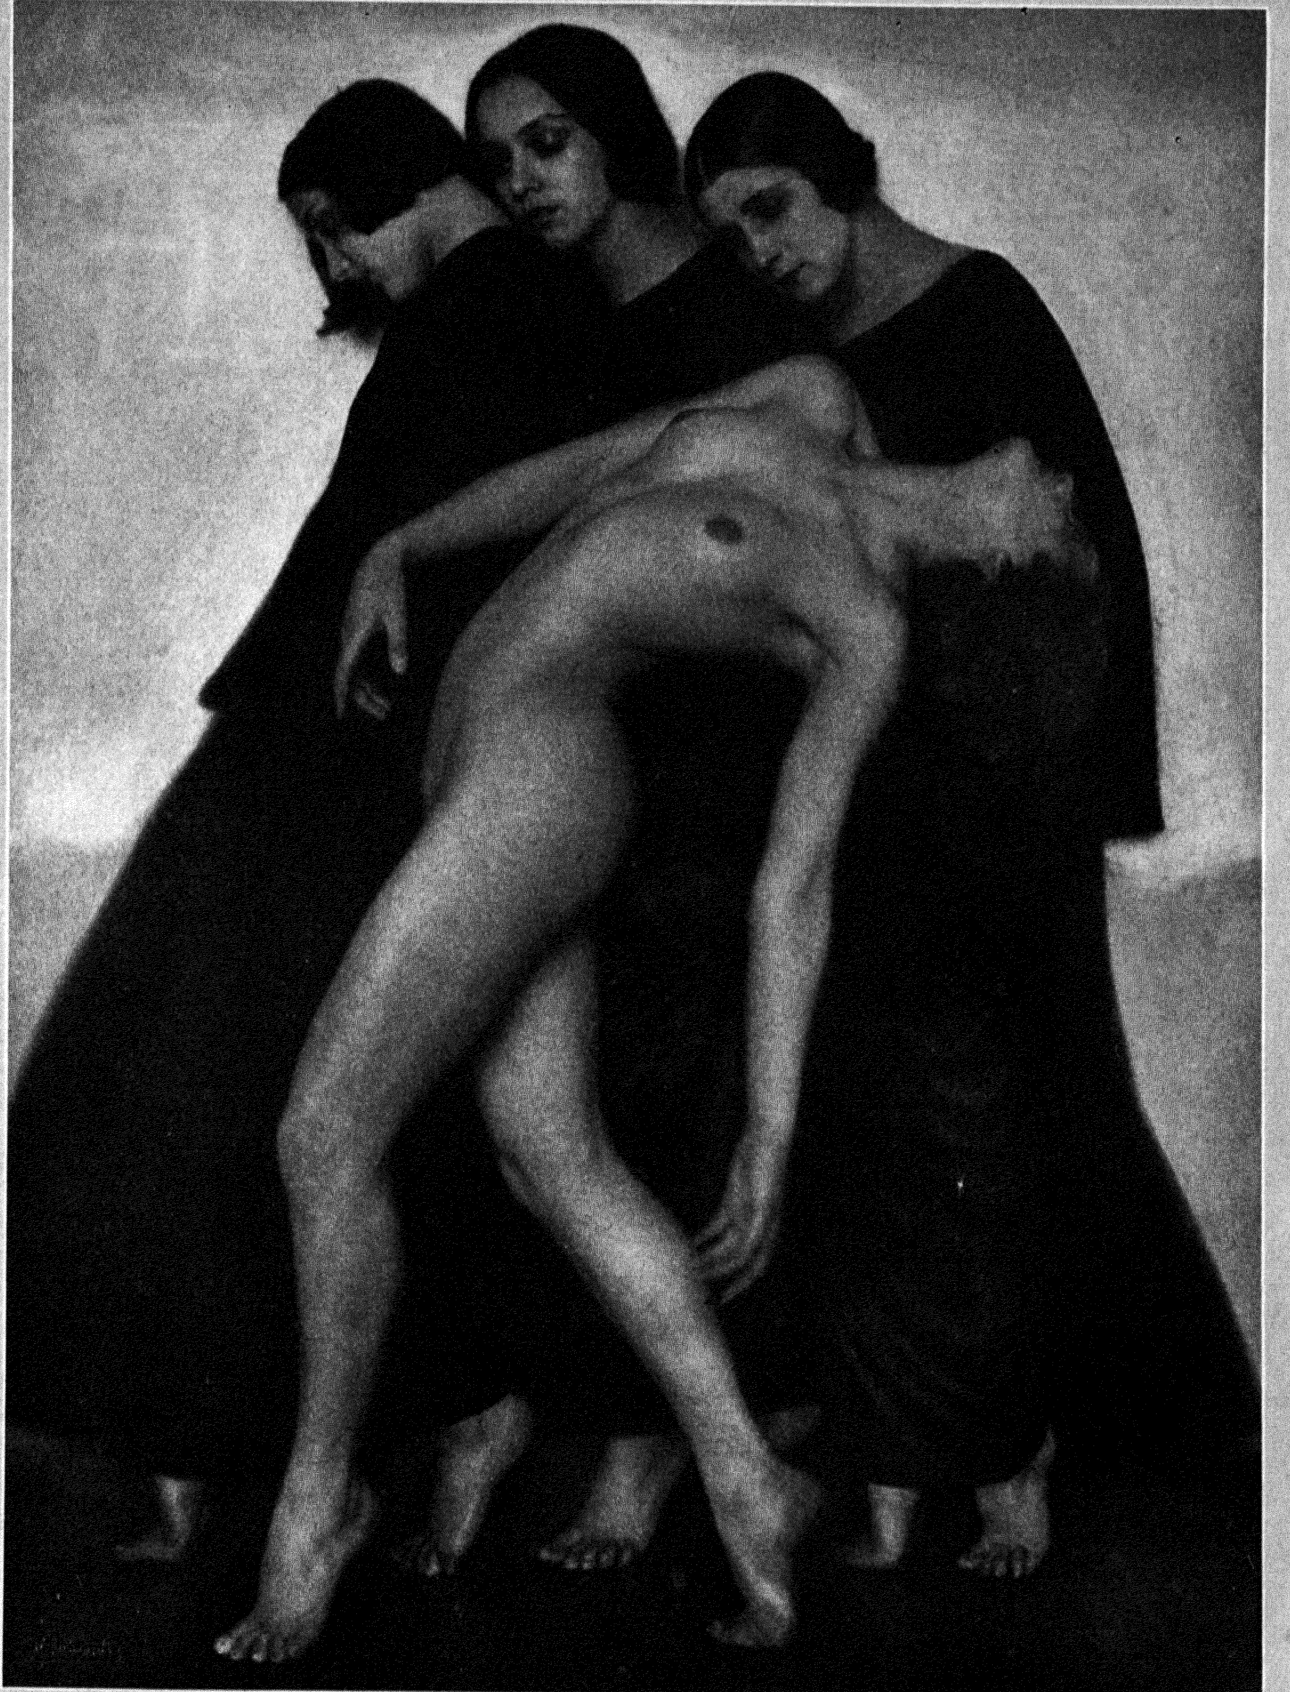
PHOTOGRAPHIC ART. The modern tendency in photography in the hands of both amateur and professional exponents is to employ the camera as a means of artistic expression. No consideration is being taken here of the widespread applications of photography in scientific and technical directions. (*See* PHOTOGRAPHY.) It is more in reference to its position in the realms of art that this article is written. The appeal to the eye is greater than the appeal to the emotions through any other sense, and in this respect photography occupies a unique position to-day as a maker of pictures. Many thousands of individuals in all parts of the world are producing photographs, with the ulterior object of their appeal to the eye as pictorial representations of incidents of interest. Unfortunately, a very large majority of those who use the camera are not artists; in this way the prestige of photography as an art is apt to suffer.

Photography can be regarded as an art in precisely the same way that any other graphic process can be regarded as an art when it is dealt with and conducted by an artist. The process is really a medium of expression, and the camera, lens and sensitive material merely the tools employed. The true artist who seeks to express himself can, within the limitations of his tools and material, do so in any medium that appeals to him for the purpose, and the measure of success that attends the result of a work of art is entirely the measure of the ability and inspiration of the artist. It is recognised that photography has limitations that are imposed by the apparatus employed. When these are recognised, the camera becomes a most facile instrument as a means of expression, and the main idea of picture making in photography is precisely the same as that which is put forward by the artist with any other medium. It is, in brief, that the individual with something to say is never inarticulate. He may find paint, or music, or the pen most responsive for his expression. Photography, with its remarkable ease of production, has solved the difficulty for many.

In 1840–1853, Daguerreotype and Calotype were very popular, and a Scottish artist, D. O. Hill, made a series of portraits in Calotype in 1844–1845, which are still regarded as remarkable examples of pictorial portraiture. (*See* PHOTOGRAPHY: *History*.) From that time onwards, a great variety of investigations and experiments were conducted in photography, and the work steadily progressed towards the simplification of methods. An outstanding development was the introduction of the gelatine process; dry plates were regularly used and the foundations of modern photography were laid. From this time onward the progress in both commercial and amateur photography became very rapid, as both the materials and the apparatus were being steadily improved year by year. Printing processes increased and cameras were simplified.

Colour Photography in Art.—The photography of coloured objects received attention in the early stages of the history of photography, when it was observed that the tones rendered in



BY COURTESY OF THE CAMERA CLUB

A PHOTOGRAPHIC STUDY IN MOVEMENT

A study by Dr. Rudolph Koppitz of Vienna; an important print, one copy of which has been acquired by the Tyng Foundation Trustees, for the permanent collection of the Royal Photographic Society. It is remarkably beautiful because of the strong massing of the figures, and for the rhythm expressed in the curved composition of the four heads, the sweep of curve of the body, and the pattern of the feet

A BRIDGE IN MONTENEGRO

A landscape photographic study by Alexander Keighley, Hon. F.R.P.S. Printing medium, bromoil. The well-chosen angle from which the old bridge is taken gives great depth of perspective to the subject. The background is well blended in, the reflections break up what would otherwise be a rather flat foreground. As a result of the low viewpoint, the stonework looms high enough to make th

monochrome on the photographic plate were not true comparative renderings of the originals, the blue end of the spectrum being rendered practically as white, and the red end of the spectrum practically as black. This irregular sensitiveness to different colours continued until Dr. H. W. Vogel found that the addition of certain dyes to the silver salt in the sensitive emulsion for plates made them more sensitive to yellow and red. This was the foundation of orthochromatic and panchromatic plates and films as they exist to-day. However, colour photography, that is, photography in natural colours, has proceeded on other lines, and may still be regarded as being in the experimental stage. (*See* PHOTOGRAPHY: *Colour Photography.*)

Processes in which coloured results have been achieved have also been arrived at in cinematography, as well as in printing processes, in which the colours have been entirely under the control of the producer of the print and can hardly be regarded as colour photography at all.

Printing Processes.—In recent times, printing processes have also been perfected and others have appeared in which personal control has placed great power in the hands of the worker for pictorial effects. In regard to the direct printing processes, one of the earliest silver methods in which the silver salts were incorporated with albumen, is no longer employed. Gelatine has taken the place of albumen and printing-out-papers have been of the variety known as gelatine-chloride. In these, chloride of silver and gelatine have formed the base of the emulsion coating the paper, the image has been printed out beneath the negative and subsequently toned. Still more recently, bromide and gaslight papers have been the most popular printing media, the former being paper coated with an emulsion of bromide of silver, and the latter with chloro-bromide of silver. Both of these are known as development papers, the image being latent after the exposure and has to be chemically developed to produce a visible image. Many varieties of chloro-bromide papers are in use to-day and are proving extremely popular printing media for pictorial workers, both amateur and professional.

On the "control" processes, gum-bichromate was popular for a period and is still used by some pictorial workers. In this process, paper is coated with bichromatised gum and a suitable pigment. After exposure under a negative, the parts that have not been acted on by light and rendered insoluble, are washed away in water. The personal control in the result is entirely in the hands of the worker, according to the desired result. To a certain extent this process is similar to the carbon process, in which pigment and bichromatised gelatine are coated on paper, and after exposure beneath a negative, the tissue is placed in contact with another support and the image developed in hot water by dissolving away the unacted-upon gelatine.

The most recent developments in control processes have been in oil and bromoil, the former being founded on the action of light on bichromatised gelatine, which is coated on to plain paper, exposed under a negative, and then soaked in water. The parts that have not been acted on by light absorb water in proportion to the light action. In this condition, those parts of the print which have been acted upon by light, and represent the shadows of the original subject, can be made receptive to an oily pigment when dabbed on with a suitable brush, and the picture thus built up in pigment. The original drawing of the photograph is retained, but the tone values are entirely under the control of the operator. In the bromoil process, a print on bromide paper is bleached in a solution in which bichromate salt appears, the bleached image taking on the same qualities when soaked in water as the printed bichromate image in the oil process, and pigment is applied in the same way.

The carbro process is a development of the carbon process in which the same principle applies, and both carbro and bromoil processes have become very popular among pictorial workers in photography, not only on account of the control in the final result that is placed in their hands, but from the fact that the prints can be made from enlargements on bromide paper made from small negatives.

In amateur work in particular, small negatives with subsequent enlarging on to bromide paper produce finished results, either in that process or in bromoil, that account for a large proportion of modern exhibition work. All the tendency to-day is towards simplifying and making smaller and more effective the apparatus for the pictorial worker. The portable hand-camera with speeded shutters, large aperture lenses, and high-speed plates and films have rendered the production of negatives of high quality possible for the multitude, while in the hands of the expert, the most perfect tools are available for use.

Controlled Processes.—The real factors that decide the success of a picture by photography are those which occur before the exposure is made and after the negative has been developed. The use of accurate apparatus, intelligently used with a knowledge of its limitations and with the employment of the right type of plate or film, is a matter within the scope of practically anyone. For the production of pictorial work which may rank as art, the mental outlook that precedes the taking of the photograph and the manipulative processes that occur in the making of the final print, will determine the artistic quality of the result. The selection of subject, choice of viewpoint and due consideration of the lighting effect are three elements of picture making, where the trained artist has the advantage, and it is in these respects that the photographer who is an artist can make the most of his subject, using the apparatus thereafter merely as a recording instrument to secure in a fraction of time the picture that has been visualized. The photographer, therefore, who is by instinct an artist, or who has had an art training, is more likely to make photographs that can rank as art than the snapshotter without these qualifications. After the plate has been exposed and the negative developed, it is in the production of the final print that the artist again finds scope for individuality. The same negative mechanically printed, on the one hand, or treated with care and thought by an artist to produce a beautiful picture by a controlled process, on the other hand, can be two widely different things. It does not necessarily mean from this that controlled printing processes employed indiscriminately, and without very definite knowledge of the final result required, will produce a picture; there is much evidence to the contrary. But many of the finest pictorial results by photography that rank high in pictorial art have been produced by one of the various controlled processes when employed by a worker who is an artist.

Bromoil Process.—Of these processes, probably the one most widely employed at the present time is the bromoil process. Bromoil has much in its favour for every worker who desires to express individual feeling and control in a pictorial photograph, and has the great advantage that, unlike many other photographic processes in which considerable control is possible a finished print on a large scale can be made with perfect facility from a small negative taken with a pocket camera. The artist, therefore, who is equipped with a small but reliable camera, and a knowledge of the picture he requires, can produce with its aid exhibition pictures of large dimensions impractical before the introduction of the bromoil process.

In the bromoil process the original negative, which should be of good quality, with the correct range of tonal values, is enlarged to the desired size by one of the ordinary methods of enlarging on to ordinary bromide paper. This enlarged bromide print then forms the basis of the bromoil print. The print, after developing, fixing and washing, is treated with a special bleaching solution which has the quality of converting the black and white silver image in the gelatine of the bromide print into a bleached image with, at the same time, a tanning action on the gelatine. This tanning action is in direct ratio with the tones of the original image. Thus, the darkest part, or shadows, of the picture become the parts that receive the greatest tanning action, the half-tones less in proportion to their strength, and the high-lights very little, or not at all. The subsequent pigmenting of the image with a greasy ink is regulated by the absorption of water in the gelatine. Where the image has been tanned or hardened by the action of the bleacher, there is not much absorption of water; whereas in the high-lights where the tanning action has not occurred, a considerable amount of water is absorbed, and those parts in turn

reject the application of the greasy pigment, whereas the hardened portions, or shadows, will "take" the pigment, and so on through the entire range from darkest shadow to high-light. The pigment is applied with a specially made flat-topped mop-shaped brush with a dabbing action, and the image is built up in pigment in any colour and any strength, according to the desires or ideas of the artist. The original outline of the image is retained, but the tones are entirely under the control of the worker. One may thus lighten shadows or darken high-lights, according to taste, and as it is largely in the matter of tonal values that many photographs suffer in quality, the amount of control that such a process places in the hands of the artist is considerable.

The working details of the above bromoil process are as follows:—The original bromide print, which may be an enlargement or made by contact, should be on any good quality bromide paper that is suitable for the process Most manufacturers of bromide paper now market a special "bromoil" paper, as some papers are "over-coated," or for other reasons are unsuitable. The print, fully developed and thoroughly fixed and washed, should be of good quality, and preferably fixed in a plain (not an acid) fixing bath of hyposulphite of soda. It may be bleached wet as soon as the washing is concluded, or it can be dried before applying the bleaching solution

The following is a good formula for the bleaching solution —

Copper sulphate	1 oz.
Potassium bromide	1 oz.
Potassium bichromate	60 grains
Hydrochloric acid	6 minims.
Water	20 oz.

For use, one part of this solution should be diluted with three parts of water. To bleach the print it should first be placed in water for a minute until limp and the surface evenly wetted, the water poured off and the bleaching solution poured evenly over the print. In from three to four minutes, the black and white image is converted into a faint brownish image. When fully bleached, the print should be thoroughly washed for a quarter of an hour and then fixed for ten minutes in a plain hypo bath, containing 2 oz. of hypo to 20 oz of water This is followed by a final washing of a quarter of an hour The bleached, fixed and washed print should then be dried, and although it is possible to proceed with the pigmenting immediately after washing, better results are obtainable by first drying

To prepare the bleached print for pigmenting it should be soaked in water at a temperature of 65° Fahr. for about half an hour. This will permit the gelatine to absorb water in inverse proportion to the shadows of the original image The print, after soaking, is placed on a pigmenting pad consisting of several thicknesses of wet blotting paper laid evenly on a hard surface such as a sheet of glass. The wet pigmenting pad is necessary to keep the print in the correct moist condition during the application of the greasy ink.

The wet bleached print is now carefully blotted with fluffless blotting paper until surface dry, and the image will be observed in the gelatine in very slight relief. The high-lights which have absorbed most water have a distinct shine, while the shadows are matt in appearance. The pigments employed are specially prepared for the purpose and are similar in character to ordinary artists' oil colours, but are much stiffer. They are obtainable in practically any colour and in different degrees of hardness, but a very hard or stiff ink can be softened by using the medium sold for the purpose or "megilp." The brushes are also specially made for the process and are approximately in the shape of a horse's hoof, with a slightly domed surface, and are usually made of fitch (pole-cat hair) It is possible to use brushes made of other hair and even of hog hair, but these are generally too coarse for fine work. One or two large brushes and some small ones are necessary for different parts of the work To apply the pigment a little of the colour should be taken from the tube and spread on a piece of glass or similar hard surfaced palette. A medium sized brush, which should be held lightly in an almost vertical position, is dabbed on the pigment and the dabbing continued on the palette until an even film of colour has been spread. The brush is then dabbed on to the surface of the prepared print, where it will be found that the pigment will adhere to those parts which formed the original image, whilst the high-lights reject the ink. From now onwards, the process is a matter of application of the pigment to the surface of the print, building up the image tone by tone until the complete picture is made visible in pigment. A certain amount of practice is necessary and desirable before the correct action for applying the pigment is acquired; but when it has been acquired, the pigmenting of a comparatively large print becomes a simple matter that is entirely under the control of the worker, who is thus able to reconstruct the subject with stronger tones where required, or high-lights filled in where necessary. A slow pressing action of the brush will tend to add more colour, while a quick hopping action will remove it. The colour should always be applied freely, and by continuing to work on the surface the texture will become finer until the right depth of tone is reached. Stronger shadows are produced by using a harder ink, which will tend to produce contrast, whilst softer inks should be used to tone down high-lights, and to make a more even tone over the entire picture. The pigmented print should be allowed to dry naturally in a warm atmosphere, and the surface should not be touched until the pigment is hard, when final spotting and cleaning up can be undertaken

Bromoil Transfer Process.—A further development of the bromoil process, producing final prints of great beauty in pigment on plain paper, is bromoil transfer. This, as its name implies, consists of transferring the pigmented image to another base of selected paper In this case the pigmented print, while still wet, is placed in contact with the new base, and between suitable supports (thin metal plates), is passed through a roller press under considerable pressure, similar to an etching press If the paper is in proper condition the pigmented image is transferred from the bleached bromide print to the new base. If the transferred image is not sufficiently strong, the original print can be repigmented and a supplementary pull made for strengthening the transfer, care being taken to secure correct registration Pictures produced in the bromoil transfer process are thus in permanent pigment on a permanent base, and comparable in the method of production with pictures in other graphic media in which an inked-up plate is pulled in a press.

Process and Expression.—Apart from the progress in processes, apparatus and materials, the individual side of photography has grown even more rapidly, but it must be admitted that, as in all other realms of art, the individual with strong personal proclivities in regard to the rendering of any particular subject matter, is always independent of the process The peculiar advantages of photography for recording incidents, textures and subjects, beautiful *per se*, should have more than a passing claim on the attention of all who may regard it solely as a means of expressing artistic thought There is, nevertheless, a tendency nowadays to confuse the process with the expression To the artist, the latter is the first consideration; the photographer who is not an artist is concerned chiefly with the process, and it is with this clear division of interest that one has an opportunity of comparing results. To know the man is frequently to know his work, but on the other hand, the product does not always betray the man The imitative faculty which the fatal facility of the camera has so readily engendered, renders the simulation of an accepted convention a matter of ease for the unoriginal. The same facility has, however, the saving grace that it enables the beginner with something original to say, to express himself nearly as well as the expert with but a few stock phrases.

The great increase in the number of photographers, both those who are attracted merely by the ease with which a picture is made, or the artists who have pictorial intentions, has been productive of vast numbers of photographic pictures; yet the original workers in the art who have produced the best pictures at various times remain pre-eminent. The multiplication and simplification of photographic processes have done much to smooth the path for the modern worker, and if a photographic exhibition of fifty years ago, or even a quarter of a century ago, could be reconstituted and

A SEA BANQUET

A seascape by F. J. Mortimer, F.R.P.S., a leading English photographer. Printing medium, bromide. There is a fine blending and graduation of the perturbed sea and the stormy sky. The flock of birds is caught at such a point that it forms a sweeping curve guiding the eye to the crest of the highest wave, the picture's intended centre of attention. The movement of the wings of gulls is beautifully expressed in the clattering of those in the foreground and the easy sweep of the gliding birds in the background

a material holder to carry sensitive plates or film, and a connecting shield to protect the sensitive material from light other than that which comes through the lens. This is generally extensible and then takes the form of a *bellows*. (*See* fig. 2.)

The cameras used for various purposes are discussed under the section *Apparatus*.

Positive materials may be used for transparencies, in which case they are *lantern slides* on glass or *positive films* (especially for motion picture photography [*q.v.*]). These materials are prepared in exactly the same way as negative materials, the emulsion being modified to give the results desired. Usually, however, negatives are printed upon sensitized *paper*. Printing papers at the present time are generally coated with a sensitive emulsion prepared either with silver bromide, *bromide papers,* or with silver chloride, *gaslight* or *developing-out* papers.

Until recently, the most usual types of sensitive paper were prepared with an emulsion containing free soluble silver compounds and were printed under the negative in strong light until the image was complete, *printing-out papers*. No development was required with these papers, which are, however, almost obsolete now except for the preparation of *proofs* submitted by professional photographers to customers.

Many other varieties of printing processes are known and some are still being used to a limited extent.

HISTORY

Photography was discovered by no one man. It was the outcome of the early observations of the alchemists and chemists on the action of light, a subject that belongs strictly to the domain of photochemistry (*q.v.*). Although the blackening of silver salts was known in 1565, it was not until 1727, when J. H. Schulze, of Germany, used a mixture of silver nitrate and chalk under stenciled letters, that it was definitely recognized that this darkening action was due to light and not to heat. These experiments were important in that, in conjunction with those of K. W. Scheele, 1777, they led to the experiments of T. Wedgwood with silver nitrate on paper and leather in 1802, which were reported to the Royal Institution of London with the suggestion that silver chloride was more sensitive. These were practically failures because of the very long exposures required, and no means were then known of removing the unaffected material and thus stabilizing the image against light.

Camera.—Leaving for the time being the question of the sensitive salts, we may turn to the evolution of the camera. This was the outcome of the old camera obscura, the invention of which is usually ascribed to Baptista Porta, 1553, though its principle had been indefinitely described by Alhazen, 1100; Roger Bacon, 1267; and others. Leonardo da Vinci, who died in 1519, described and pictured a camera obscura in an unpublished manuscript. In 1550 J. Cardan suggested the use of a speculum or concave mirror in front of the instrument, and D. Barbaro, 1568, proposed convex lenses and the use of a diaphragm to secure greater sharpness of the images. E. Danti, 1573, corrected the reversed image by means of a mirror behind the lens, a device still in use. F. Risner, who died in 1580, described in his works published in 1606 the methods of enlarging and reducing, and a portable box in lieu of the cumbrous fixed hut in use until then. Porta in his second edition, 1589, of which an English translation was published in 1658, was the first to introduce the use of the convex lens in the camera. Kepler, the famous astronomer, in his work on optical astronomy, 1604–1611, described the use of a concave lens behind the convex to obtain larger images, and thus anticipated the telephoto lenses of the present day. In J. Zahn's book, 1665, there was described a portable camera obscura with two or three lenses, to secure greater brilliancy of the image, and side wings to shield it from extraneous light; thus with the reversing mirror he antedated a type of modern camera. At the beginning of the eighteenth century the portable camera obscura had become a regular article of commerce and was used to obtain sketches from nature.

The Beginnings of Photography.—A. Senefelder discovered lithography in 1796, but, though it was introduced in Paris in 1802, it was not until 1813 that it became a success and a fashionable hobby. From this date until 1817 J. Nicéphore Niepce was engaged in an examination of the French natural stones to find one suitable for the process. Since he was unable to draw, his son, Isidore, undertook this work, and when the latter was called for military service, Niepce was impelled to produce the images automatically. In conjunction with his brother Claude, Niepce first essayed photography with silver chloride on paper. The light-sensitiveness of iron, manganese, acids, and other compounds was tested, stone, metal, and paper being used as supports. Finally, guaiacum resin was tried and then asphaltum, or bitumen of Judea, which had been in common use as an etching ground since the days of Rembrandt. This, becoming insoluble in its usual solvents by the action of light, gave not only a resist for the etching of metal plates but also transparent images on glass. A successful result was obtained in 1822, and thus it may be said that the first permanent photograph was made in that year by Niepce.

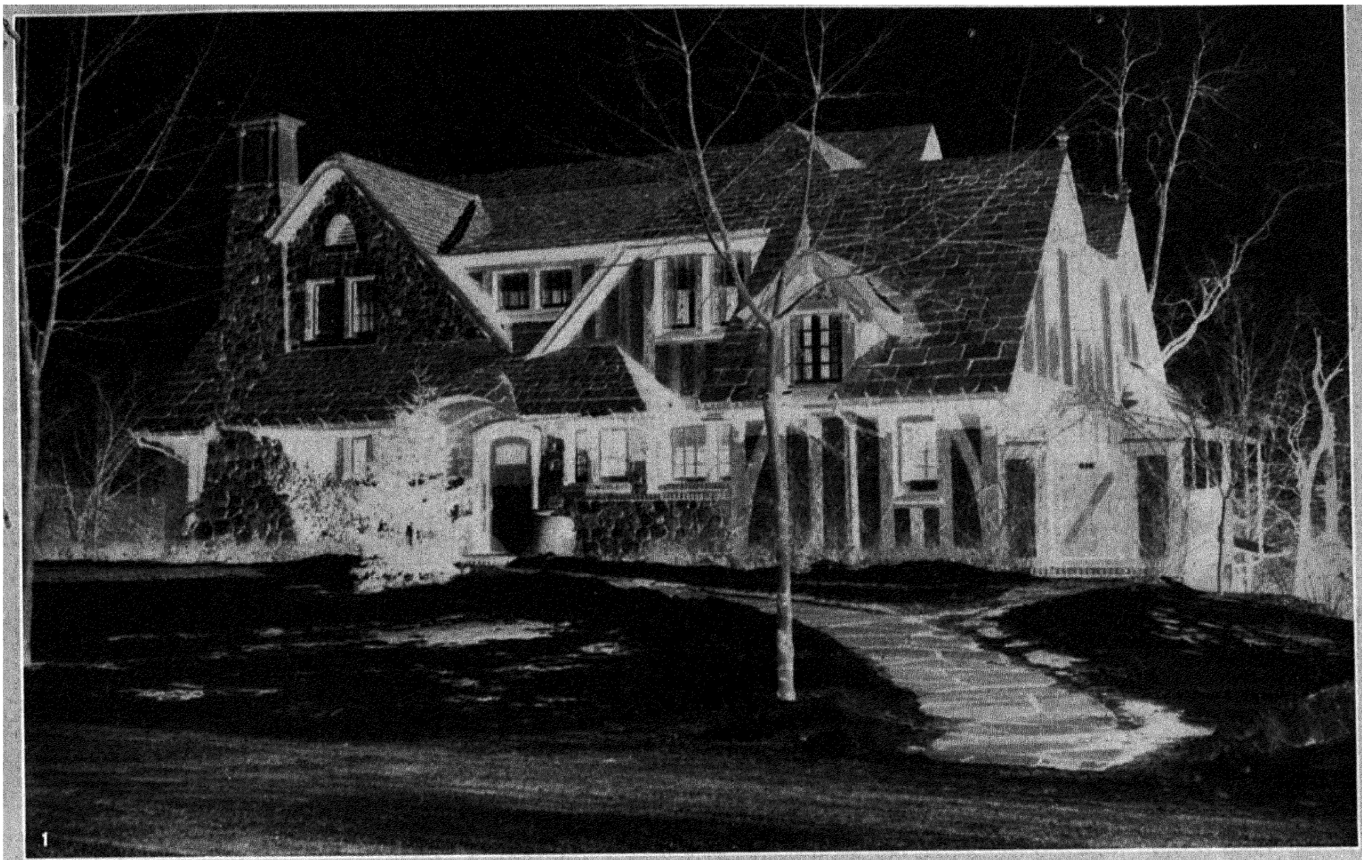
The next three years were required to perfect the process of heliography, as it was called, and in 1826 an etched metal plate was sent to M. Lemaitre, of Paris, to be printed. In order that the pictures should be more distinct, they were exposed to the vapors of iodine. The highlights of the plates consisted of hardened bitumen; the shadows, of the bare metal; thus the contrasts were very poor, which led to the use of tin instead of copper. Lemaitre suggested silvering copper plates. These two facts are of importance in the subsequent history.

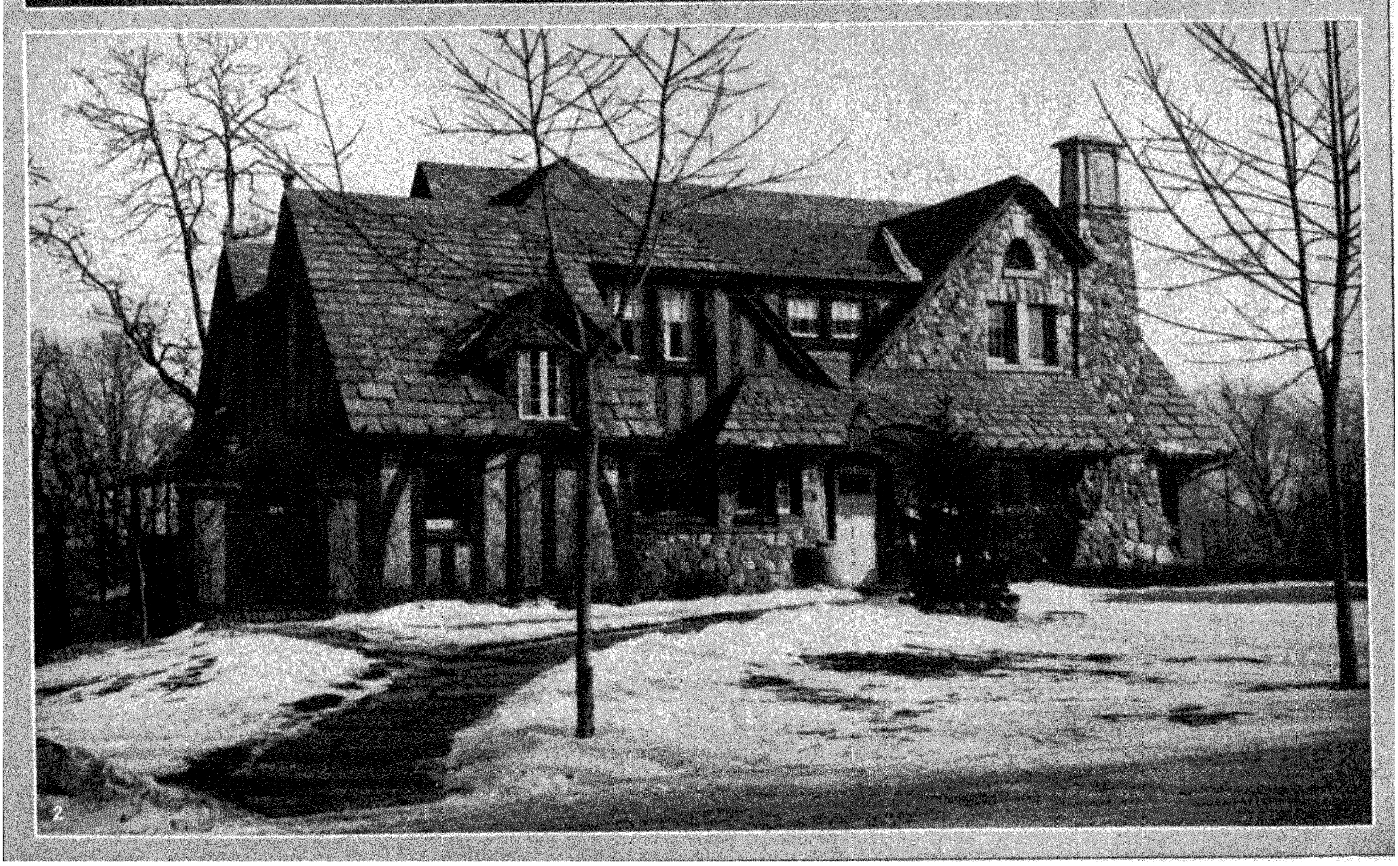
Daguerreotype.—In 1826, Daguerre, a painter who had experimented with silver salts, heard of Niepce's work and approached the latter as to the formation of a partnership. This was consummated in 1829. The work which Daguerre had done with Niepce had drawn their attention to the light-sensitiveness of silver iodide, and Daguerre discovered accidentally that the effect produced by exposing an iodized silver plate in a camera would result in an image if the plate were fumed with mercury vapor. The inventions of Niepce and of Daguerre were published to the world simultaneously by the French Home Minister in a bill presented to the House of Deputies proposing a national reward to the inventors. A full description of their methods was presented on August 19, 1839, at a meeting of the Academy of Arts and Sciences.

The introduction of the Daguerreotype process was attended by complete success. The process required much care and skill. A silvered copper plate was buffed and burnished to a high degree of polish. It was then iodized by careful fuming with iodine, and later (1840) resensitized with bromine, and then given an exposure the duration of which was of vital importance. At first, exposures of minutes in bright sunlight were necessary, but later exposures were secured in a few seconds under favorable conditions. The development was effected by placing the exposed plate over a cup of mercury heated to about 75° C. The image was then fixed with a solution of thiosulphate of soda and toned by treatment with gold chloride. The results obtained were excellent when all the operations had been carried out correctly, and the process flourished, especially for portraiture, until it was superseded by the wet collodion process in 1851.

Calotype.—A preliminary notice of Daguerre's success was made by Arago to the Academie des Sciences in Paris on Jan. 7, 1839. This caused Fox Talbot, an Englishman, to write to Arago claiming priority in regard to the obtaining of a picture in the camera, and having rendered it permanent. Talbot began his experiments in 1834, using the camera obscura with silver chloride and common salt or potassium iodide as fixing agents. A communication was made to the Royal Society of London on Jan. 30, 1839. But not until a month later did he disclose his working method, which then involved silver iodide with excess of the nitrate, and fixation with sodium thiosulphate. The solvent action of this for silver salts had been discovered by Sir J. W. F. Herschel in 1819. Talbot's process was called "Calotype," and the light image was developed with gallic acid, the action of which had been discovered independently by the Rev. J. B. Reade, but had not been published by him.

The developed image on a sheet of Calotype paper was the





EXAMPLES OF NEGATIVE AND POSITIVE PHOTOGRAPHIC PRINTS

exact reverse, as far as light and shade were concerned, of the original image. Such a picture was termed by Sir J. Herschel in 1841 a "negative." Since paper is a semi-transparent substance whose transparency could be increased by waxing or oiling on the side opposite to the image, Talbot was able to obtain true copies or positives of any negative by simple contact printing upon another piece of sensitized paper. Talbot's process should be considered as the first stage in the real line of photographic development, the notable inventions of Daguerre and Niepce being merely bypaths whose chief importance was the mental stimulus they gave to photographic evolution. The disadvantages of Calotype were the somewhat long time required for printing and the structure of the paper.

Herschel suggested the use of glass plates and the deposition of silver chloride thereon. In 1848 Niepce de Saint-Victor, the nephew of Nicéphore Niepce, suggested albumen as the vehicle for the sensitive silver iodide. This process, called "Niepceotype," held its own until 1851, when Scott Archer, an English architect, published his wet collodion process, which is still in use in photomechanical establishments.

Collodion Process.—Collodion, a solution of nitrocellulose in alcohol-ether, was first prepared by Maynard of Boston for medical purposes. Schönbein, the Swiss chemist, discovered nitrocellulose in 1846. To a solution of pyroxylin in ether and alcohol, Archer added a soluble iodide, usually with the addition of a little bromide, and coated a clean glass plate with the iodized collodion. In the darkroom, the iodized collodion was sensitized by immersion in a bath of silver nitrate and formed silver iodide with excess of silver nitrate. The plate was exposed wet in the camera, developed by pouring on a solution of pyrogallol containing acetic acid, and fixed with a strong solution of thiosulphate of soda for which cyanide of potassium was later substituted. Archer's collodion process was not patented, and in three or four years it displaced both Calotype and Daguerreotype.

The necessity for preparing the plates immediately before exposure and developing them immediately after considerably limited the practice of photography. Spiller and Crookes suggested bathing the prepared plates in a solution of a hygroscopic salt, so that they could be kept some time both before and after exposure. This was followed by the use of hygroscopic substances of all kinds.

Collodion Emulsion.—In 1864, B. J. Sayce and W. B. Bolton described the preparation of an emulsion of silver bromide in collodion. With this preparation, the nitrates—the by-products of the formation of the silver halide from the nitrate and alkaline halide—were left in the emulsion. In 1874, W. B. Bolton showed that it was possible to wash these nitrates out, and his methods are still followed.

Collodion emulsion was a practical advance on wet collodion but involved no improvement in the matter of sensitivity. Fundamental contributions to this were made by the introduction of alkaline development by Major Russell in 1862. A considerable increase of sensitiveness was obtained with collodion emulsion, but the full fruit of this was reaped only with the introduction of gelatino-silver bromide dry plates.

Gelatine Emulsion.—In 1871, Dr. R. L. Maddox made an emulsion of silver bromide in essentially the same manner as that used for making collodion emulsions but he replaced collodion by gelatine. The matter was followed up by other experimenters, among whom may be mentioned J. Burgess and J. Kennett. Kennett placed on the market a dry, washed emulsion which photographers could dissolve in warm water and use as a coating on glass and thus produce their own plates.

A great amount of experimental work was at once commenced on gelatine emulsions, the records of which filled the photographic journals between 1873 and 1885. The by-product salts were removed by washing. Abney recommended the use of iodide in small quantity with the bromide and found that this made it possible to obtain faster emulsions with less fog. Digestion, or "ripening" as it was called, came into use—long digestion at low temperatures being suggested by Bennett—in 1878, and digestion with ammonia was used in 1876 by J. Johnson and in 1879 by Monckhoven, who employed precipitation in ammoniacal solution as the basis of a process of manufacturing dry plates.

In 1877, the commercial plates of the Liverpool Dry Plate Company, Wratten and Wainwright, and B. J. Edwards were introduced, and by 1879 comparatively rapid dry plates were available on the market similar in type to the slower varieties of plates used to-day.

After this period, amateurs gradually ceased their researches, and mass manufacture became general. Considerable increases in sensitiveness were made between 1890 and 1900, but since the latter date there has probably been little advance in the maximum sensitiveness that can be obtained, although materials of high sensitiveness are made with much greater regularity and with greater uniformity than was the case formerly.

It is interesting at this point to record the advance made in photography in terms of the relative sensitivity of the process.

Process	Date	Time of exposure
Heliography	1827	6 hr.
Daguerreotype	1839	30 min.
Calotype	1841	3 ,,
Wet Collodion	1851	10 sec.
Collodion Emulsion	1864	15 ,,
Gelatine Emulsion	1878	1 to $\frac{1}{200}$ sec.
Gelatine	1900	$\frac{1}{1000}$ sec.

Colour Sensitivity.—The silver halides are sensitive chiefly to the blue, violet, and ultra-violet rays; hence, all other colours are reproduced as dark greys or blacks. In 1873, H. W. Vogel of Berlin discovered that the addition of certain dyes to the emulsion or immersion of the coated plates in a solution of dye increased the sensitiveness to the less refrangible colours.

Following this, Waterhouse found that eosin sensitized collodion emulsion, and shortly afterwards Clayton and Tailfer found that eosin would sensitize gelatine emulsions. They obtained a patent for its use in England and France, and their plates were placed on the market under the name of "isochromatic" plates. In 1884, eosin was replaced by erythrosine, which was found by Eder to be a better sensitizer, and since that date erythrosine has been used almost exclusively for the use of the so-called "isochromatic" or "orthochromatic" materials. In 1902, Miethe and Traube of Berlin found that ethyl red, an isocyanine dye, gave strong colour sensitiveness as far as the orange of the spectrum, and in 1905, Homolka, working at the Hoechst Dye Works, discovered Pinacyanol, a dye of structure somewhat similar

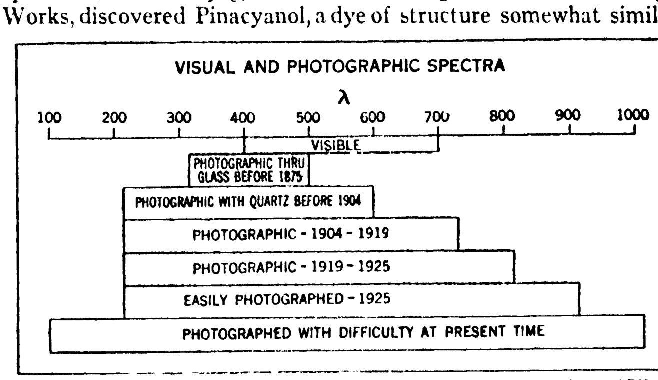

FIG. 3.—PROGRESS IN THE COLOUR SENSITIZING OF PHOTOGRAPHIC MATERIAL

to ethyl red but which sensitizes very powerfully throughout the red.

It was now possible to make "panchromatic" plates, which would photograph the entire spectrum without difficulty, and such plates were placed on the market in 1906. Further advances in colour sensitizing during recent years have extended the photographic spectrum into the near infra-red, and the accompanying figure illustrates the advance made since 1875 in widening the spectral range. (*See* fig. 3.)

Film.—The weight and fragility of the glass support led to attempts to replace it by lighter and flexible substitutes. In 1884, the film roll system of photography was invented by W. H. Walker, the emulsion being coated on paper, and a machine for

continuously coating photographic paper in long rolls was patented by George Eastman in 1885. The sensitized paper was loaded into a roll holder which could be attached to the back of a camera in the same position as a plate holder. At first, the paper was waxed to reduce the printing time, but later a stripping film was used, this consisting of a temporary paper base coated with soluble gelatine, which in turn was coated with a gelatine emulsion.

This stripping film was used in the first portable roll film camera marketed in 1888—a box type camera with two rolls, a supply spool and the wind-up spool. The pictures were circular, about two inches in diameter, and the operator had merely to point the camera and press the button. When the film was used up, the whole camera was returned to the manufacturing company, who developed and printed the pictures and reloaded the camera.

Eastman made experiments to produce a flexible film from collodion, but the ether-alcohol solutions would give only films which were too thin to be of practical use. Finally the use of wood alcohol as a solvent for nitrocellulose was discovered, and a flexible film base was marketed in rolls in 1889. In the same year, J. Carbutt introduced emulsion coated on flexible sheets of plastic nitrocellulose compound cut from blocks. The new flexible film was applied at once by Edison to the photography of motion pictures.

In 1891, daylight loading film was made. The film was wound on a wooden core inside a light-tight box and black cloth leaders were attached to the ends of the film. Later, the film was wound inside a protective sheet of black paper leaving sufficient overlength to permit loading of the camera without fogging the sensitive film. This was further modified in 1903, when a non-curling film was produced by coating the back of the film with plain gelatine.

In 1913, roll film packing was further modified by spooling the film in a thin and translucent red paper, the film being protected from light by the use inside this of "carbon" paper similar to that used for duplicating on a typewriter. After exposures are made, the photographer can write on the red paper with a stylus through an opening in the back of the camera. The pressure of the stylus removes some of the opaque black carbon from the sheet, so that on exposure to light the film is exposed along the tracks of the writing, and the image develops with the negative and serves for its identification.

In 1895, positive film was introduced for the printing of motion pictures, the film used previously being of the negative variety only. In 1909 slow burning motion picture film was first made by the substitution of cellulose acetate for cellulose nitrate as the plastic used in the preparation of the base.

Another method of packing films was invented in 1903 and was introduced on the market under the name of "film packs." These are now used mostly in cameras of the type originally designed for employment with dry plates. They have the advantage of not requiring a special roll film back. During the last ten years flat cut films have replaced plates to a considerable extent in professional photography, although large numbers of plates are still used in that field.

In 1917, X-ray films coated on both sides with emulsion were introduced. Owing to the transparency of the material to the X-rays, this enables double the density to be obtained, and the use of this film is now general throughout the world, it having almost entirely replaced plates in radiographic work.

In 1923, motion picture film 16 mm. wide on cellulose acetate base was introduced packed in such a manner that it could be loaded into small motion picture cameras without the use of a darkroom. This film was designed for finishing by a reversal process, in which the first negative is removed by a bleaching bath, and a positive is then printed on the remaining silver bromide. In France a similar film was made 9½ mm. wide. The introduction of this film has led to a great advance in amateur cinematography.

Developing Agents.—In the Calotype process gallic acid was used as the developer for the latent image, but in 1851 Regnault of Paris and Justus Liebig simultaneously discovered the more energetically-acting pyrogallol, which actually allowed shorter exposures to be given. This was used also at first for wet collodion, though it was later replaced by an iron salt, and for dry collodion plates. Until 1861, free silver nitrate was an important ingredient of developers; but in that year Wardley proved that pyrogallol alone could be used. C. Russell and J. Leahy independently announced alkaline pyrogallol development, the former suggesting also an alkaline bromide as restrainer. Even after the introduction of the gelatine plate, pyro-ammonia was the only developer used until 1884, when the alkaline carbonates became general. In 1880 Abney discovered the developing properties of hydroquinone. C. Egli and Arnold Spiller recommended the use of hydroxylamine in 1884. In 1888, M. Andresen of Berlin patented the use of paraphenylene diamine, paratoluidine diamine, and xylidene diamine as developers. In 1891, he patented the use of paraminophenol and its derivatives, especially monomethylparaminophenol, known under the trade name of "metol."

Printing Processes.—In turning to the positive processes, the first was with silver chloride and excess of silver nitrate on plain paper, which gave prints with a rather sunken appearance, the image being more or less buried in the fibres of the paper, and daylight was essential for printing. Blanquart-Evrard, in 1847, suggested the use of albumen to keep the sensitive salt more on the surface. In the same year, Romieu proposed salting with a mixture of alkaline bromides and chlorides containing gelatine and subsequent floating on silver nitrate solution. A few years later, the first coat of albumen was coagulated and a second applied, which gave a more brilliant glossy surface. The colour of prints obtained on these papers was an unpleasant foxy colour, and to darken this an acid was added to the fixing bath, thus causing sulphur toning. Le Gray, in 1850, proposed the use of a gold salt to improve the colour, and an alkaline gold bath was recommended by Waterhouse in 1858. De Caranza, 1856, recommended the use of platinum in lieu of gold. Albumenized paper made in this way and toned with gold remained the standard photographic printing medium until 1890.

A. Gaudin had suggested an emulsion of silver chloride in collodion for printing-out. This was revived by Wharton Simpson, in 1865. Paper thus prepared was introduced commercially by Obernetter three years later. Humbert de Molard, 1855, proposed to precipitate silver chloride, wash and suspend it in solution of starch or gelatine and paint the mixture on to paper. The same process was revived by Smith and Palmer in 1865 and by Abney in 1882. From this date, gelatino-chloride or printing-out paper came into general use, and eventually completely displaced albumen. Printing-out papers are still much used in Europe, chiefly collodion papers containing a gold salt that obviates the necessity of toning, but in America their use is limited to the production of rough proofs. Commercially they have been superseded by development papers.

Silver bromide with excess silver nitrate was used by Fox Talbot, and J. W. Swan in 1879 patented the use of paper coated with silver bromide emulsion not containing excess silver for development. It did not, however, come into general use until marketed by Eastman and by Just in 1883. Eder and Pizzighelli published, 1881, an exhaustive paper on gelatinochloride of silver with development, and the former, two years later, described a chloro-bromide emulsion. Chloride developing paper was introduced by Marion in England under the name of "Alpha" in 1889, and by Baekeland in America as Velox. Year by year since then the use of this paper has increased, special types, including a great variety of surfaces, being used for amateur and professional work.

Non-silver Printing Processes.—Robert Hunt was the first to utilize the light-sensitiveness of ferric oxalate in combination with a platinum salt in the hopes of obtaining images in that metal. But the process was a failure because he did not recognize that the ferrous salt, formed by the action of light, must form a complex salt in order to reduce the platinum salt to the metallic state. W. Willis in 1878 introduced the first workable platinum process. The great advantage of this process is that the pictures are permanent, as platinum is one of the most resistant of all metals. A modification of the process enables a platinum deposit of a sepia colour to be obtained, and for many

years sepia platinotype was the favourite printing process for results of the highest quality. The high cost of platinum and the ease with which development papers are worked has recently decreased the use of the process.

Vauquelin in 1798 had discovered the light-sensitiveness of silver chromate; Suckow, in 1832, observed that the bichromates were reduced by light in the presence of organic matter. Mungo Ponton, 1839, used paper treated with potassium bichromate. Becquerel, 1840, and Hunt, 1843, made improvements; but Fox Talbot first pointed out, 1852, that bichromated gelatine became insoluble in light, and this was patented as a resist for photogravure, for which it is still used.

Pretsch, Poitevin, Testud de Beauregard, Garnier and Salmon, and Pouncy, 1859, devised carbon processes, in which carbon itself in a finely divided state was used as the pigment in bichromated gelatine. But they failed to recognize the important point that, as the light acted first on the outer surface of the gelatine, those parts underlying the half tones and highlights would still be soluble; hence, on developing with warm water, they would have no anchorage to the support and would be washed away. J. W. Swan in 1864 patented the production of carbon or pigment prints by the transfer of the exposed pigmented tissue to a temporary support, on which it was developed from the back. Practically, his process is in use to-day, and its long scale of gradation, the possibility of using pigments of any colour, and the great stability of the pictures are much in its favour, though the necessity of day or arc-light for printing is against it.

T. Manly, 1905, patented a pigment process in which a developed silver print was squeegeed into contact with pigmented tissue saturated with potassium ferricyanide and bichromate. These salts migrated to the silver image, bleached it, and the reduction products wandered back to the tissue, rendering it insoluble in ratio to the amount of silver in the picture, as though the tissue had been exposed to light under the negative. A modification of this, known as "Carbro," was introduced some years ago.

In 1905, G. E. Rawlins reverted to an old process suggested by Mariot in 1866. Gelatinized paper is sensitized with bichromate, dried, exposed under a negative, freed from excess salt, and inked up with a greasy ink, which adheres to only the light-affected parts. Somewhat similar is the bromoil process first suggested in 1907 by E. J. Wall and worked out by Welborne Piper. This utilizes the principle stated by Howard Farmer in 1889 that finely divided silver imbedded in gelatine reacts with bichromates and renders the contiguous colloid insoluble. A bromide print is treated with a hardening and bleaching solution, fixed, washed and dried, then soaked in water, and inked up with a greasy ink, which takes only on those parts where there was silver. These processes have been used particularly by artistic workers, because there is complete control over the gradations and tones of the pictures, and any coloured ink may be used.

There is practically no advance to be recorded in the iron printing processes, which are chiefly used for architects' and draughtsmen's plans, since Herschel's introduction of cyanotype in 1842. G. Kögel has patented, however, the use of diazoanhydrides, nitro- or sulphonic derivatives of naphthalene, for paper that may be used for the same purpose; this process is known as "Ozalid." The advantage of it is that as the image is developed and fixed by gaseous ammonia there is no distortion caused by a wet treatment.

THE BRANCHES OF PHOTOGRAPHY

Amateur Photography.—The use of photography for making personal records has extended very greatly since portable cameras and sensitive materials were introduced, and the tendency is continually towards a simplification of the work to be done by the user and a diminution in the amount of expert knowledge required to get good results. This has resulted in the establishment of commercial firms to develop and print photographs made by the amateur, so that the great majority of photographs are now taken by those whose knowledge of the subject is limited to that necessary for making the exposures. The cameras used are chiefly of the folding type using a cartridge of film and are often of very small size.

The film can be loaded into the camera without the use of a darkroom and removed after exposure for development. For development, the films are hung by clips in deep tanks. They are printed by artificial light upon gas-light or developing-out papers, which are made in different degrees of contrast to suit the negatives obtained. As a general rule the photographic dealers will deliver prints from an exposed roll of film within two days. Enlargements are made upon bromide paper, frequently by means of enlarging cameras in which the focus is automatically maintained correct while the scale of magnification is varied. (*See* Plate III., fig. 5.) In addition to roll films, films in packs are largely used, each separate unit having a tab of paper attached to it by which it can be withdrawn after exposure. A small number of cameras still use plates or flat cut films in suitable holders.

Photographers who prefer to develop their own films usually employ a so-called "developing tank." (*See* Plate II., fig. 1.) The film is placed in a wooden changing box, in which it can be wound up with a light-tight flexible apron on to a spool. This spool together with the film is then transferred to a metal tank fitted with a light-tight lid, in which the film is developed.

When a darkroom is employed, the duration of development can be determined by one of three methods:

(1) By observation; the development is carried on until the strength of the image is judged sufficient. This requires much experience and is not to be recommended.

(2) By factorial development; this system was introduced by Alfred Watkins of Hereford, England. The number of seconds that elapse from immersion in the developer to the first appearance of the image is noted. This time is then multiplied by a certain number called the "developing factor," to arrive at the total time of development. The factor depends upon the material used and the composition of the developer. The method gives good results in the hands of an experienced worker.

(3) Development for a fixed time at a definite temperature. This method possesses the maximum of advantage and reliability. It is always used when negatives are developed in tanks and has largely displaced the other methods.

Printing can be done either in a printing frame or with a small printing box in which the negative is placed on a sheet of glass, the paper placed on it, and a platen then brought down which secures contact and simultaneously lights an electric lamp under the negative. A grade of paper suitable to the contrast of the negative is chosen, and exposure is judged from the density of the negative

Almost all the cameras used in amateur photography are designed primarily for use in the hand and are only occasionally used upon tripods. In addition to the small portable cameras, many amateur photographers use reflex cameras and folding cameras fitted with focal plane shutters. (*See* PHOTOGRAPHY: *Apparatus*.)

Advanced amateur photographers have contributed very much to the development of photography. They were among the first to employ colour sensitive plates, to use lenses of special types, such as telephoto or extremely wide aperture lenses, to study the printing processes, and to develop the artistic use of photography. (*See* PHOTOGRAPHY: *Pictorial*.)

Professional Photography.—The earliest photographic portrait appears to be the Daguerreotype taken of his sister by J. W. Draper of New York in 1840. The sitter was made up with white powder and photographed in full sunlight, an exposure of 5 minutes being given. The Daguerreotype process came into general use for portraiture, the plates being protected by glass in small leather cases, and these represented the common form of portraiture until the wet collodion process was introduced in 1851.

The early collodion portraits consisted of a glass negative developed so that the silver deposit was white and backed with a black varnish or material so that they appeared as positives resembling Daguerreotypes. They were sold in cases exactly

resembling those used for Daguerreotypes and are often mistaken for Daguerreotypes at the present time. They are properly known as Ambrotypes.

It was not until about 1860 that Ambrotypes were supplanted by albumen prints made from collodion negatives, these being made generally in two standard sizes—the carte-de-visite and cabinet. These were preserved in albums, and the period when the family album was in common use represented that of greatest prosperity for the professional photographer. These portraits were taken in glass covered studios arranged to supply the maximum of daylight. Elaborate backgrounds were used, and studio accessories of ornate and artificial type were commonly employed. Retouching on the negative was used often to an excessive degree, this being necessitated both by the vanity of the sitter and the pronounced ultra-violet sensitiveness of the collodion plate. In considering the evolution of portrait photography, it should not be forgotten that as early as 1843 D. O. Hill in Glasgow had used the Calotype process to make portraits which in dignity and artistic quality rival any that have ever been produced.

The "album" period lasted after the introduction of the dry plate, and modern photographic portraiture may be held to have had its beginnings only about 1900. The albumen process, however, was superseded by shiny, purple, gold-toned printing-out papers.

The modern development of portraiture has been influenced largely by "home portraiture" and by the use of artificial light in the home or elsewhere. The first arose from the entry into the profession of artists, usually without studio experience, who believed that they could obtain more characteristic portraits in the everyday surroundings of patrons, and of experienced photographers who operated over a wide field without the need of maintaining an expensive studio. This type of photography has become very successful, especially in the United States.

Artificial light was introduced primarily to make the photographer independent of the vagaries of the weather. Since the use of artificial light made any large room suitable for use as a studio, and the influence of home portraiture encouraged the replacement of artificial backgrounds and accessories by the natural surroundings of a room, the studio has lost much of its artificial character.

In a reaction from the elaborate backgrounds of the '90s, many photographers employed almost perfectly plain backgrounds for portraiture, these being conspicuous in the work of Hollyer, Craig Annan, and Furley Lewis in England, of Hofmeister and Perscheid in Germany, and of MacDonald in New York.

At the present time portraits of the better class are usually supplied of large size, 6×8 in. and upwards, and in folding mounts which protect the surface of the print.

In the United States negatives are taken very largely on flat sheets of portrait film, developed in tanks in a vertical position, and printed either by contact on developed chloride papers or by enlargement on bromide or chloro-bromide papers. The use of enlargement for making portrait prints has increased greatly recently owing to the introduction of automatically focusing projection printers. In Great Britain printing is done chiefly by contact on bromide paper and on the more sensitive grades of chloro-bromide. Retouching is still used very largely in portraiture, but the increasing use of panchromatic materials will undoubtedly diminish its extent in the future.

In addition to the high grade professional portraiture discussed here, there is a very large industry in the supply of cheap portraits to the masses, especially in the large cities and the pleasure resorts. The negatives are taken by artificial light on strips of film or in a camera so arranged that several can be taken on one plate and are printed as rapidly as possible on strips of paper which are usually cut to the size of post cards or even smaller. A still cheaper grade of portrait is produced by the "ferrotype" process on dry collodion coated on black japanned metal, this being the modern representative of the Ambrotype process. Similar pictures made with wet collodion have survived from 1860 as "tintypes."

A recent introduction consists of an automatic apparatus by which on the introduction of a coin into a slot a series of photographs are taken and finished by a reversal process, a strip of positives on paper being delivered to the customer in a few minutes.

Commercial Photography.—In addition to portraiture the professional photographer has been accustomed to make miscellaneous photographs of buildings, machinery, or articles of merchandise which might be required for commercial purposes, but in the last 15 years this branch of photography has developed so greatly that it has become the work of a specialized group of "commercial photographers," and except to a small extent it is no longer carried on by portrait photographers.

The work of the commercial photographer is of the most varied character, but it may be divided into three sections according to whether the photographs are intended for use as a record, often necessary in engineering and construction work, to replace samples for the salesman to carry in soliciting orders, or for use in advertising. In the second field the photographs are often coloured by hand, a process which is almost obsolete in other branches of photography but which is rendered necessary by the absence of any cheap and satisfactory process of natural colour photography upon paper. Photographs for use in advertising may be designed either to represent the article, as in those employed for catalogue illustrations, to show the actual use of the article in the hands of the consumer and thereby to create a desire for it, or merely to attract attention. This field of commercial photography gives great scope for artistic composition and has developed very greatly of recent years.

Two characteristics of commercial photography are its use of suitably trained models, who are chosen with the greatest care, and the employment of special means for the photography of coloured objects.

Panchromatic materials and light filters were adopted by commercial photographers as soon as they were available, and a thorough understanding of their use is essential to satisfactory work at the present time. The apparatus used in commercial photography is remarkable chiefly for its adaptability and portability; it is necessary to photograph all kinds of objects in all sorts of places, and only a small portion of the work can be done in the studio.

Commercial photography is growing very rapidly, and there is little doubt that it will continue to grow for a number of years.

Applied and Scientific Photography.—Photography is used in science and industry primarily to make a record which can then be studied and measured. It can also be used to facilitate the copying of documents, etc., photographic methods having the advantage of accuracy and speed. For this work a so-called "Photostat" camera is used in which a roll of paper is employed on which the document is recorded. (*See* Plate III., fig. 2.) The result is in the form of a negative and for many purposes these negatives are satisfactory; if positives are required, the negatives are re-photographed in the same camera.

In addition to its use in libraries, and so forth, for circulating extracts from books or copies of letters and other documents, photographic recording is now used very largely for the preparation of legal records, especially in connection with real estate. For such purposes a special "ledger" paper is used coated with emulsion on both sides, so that the photographs can be bound into books in the minimum space.

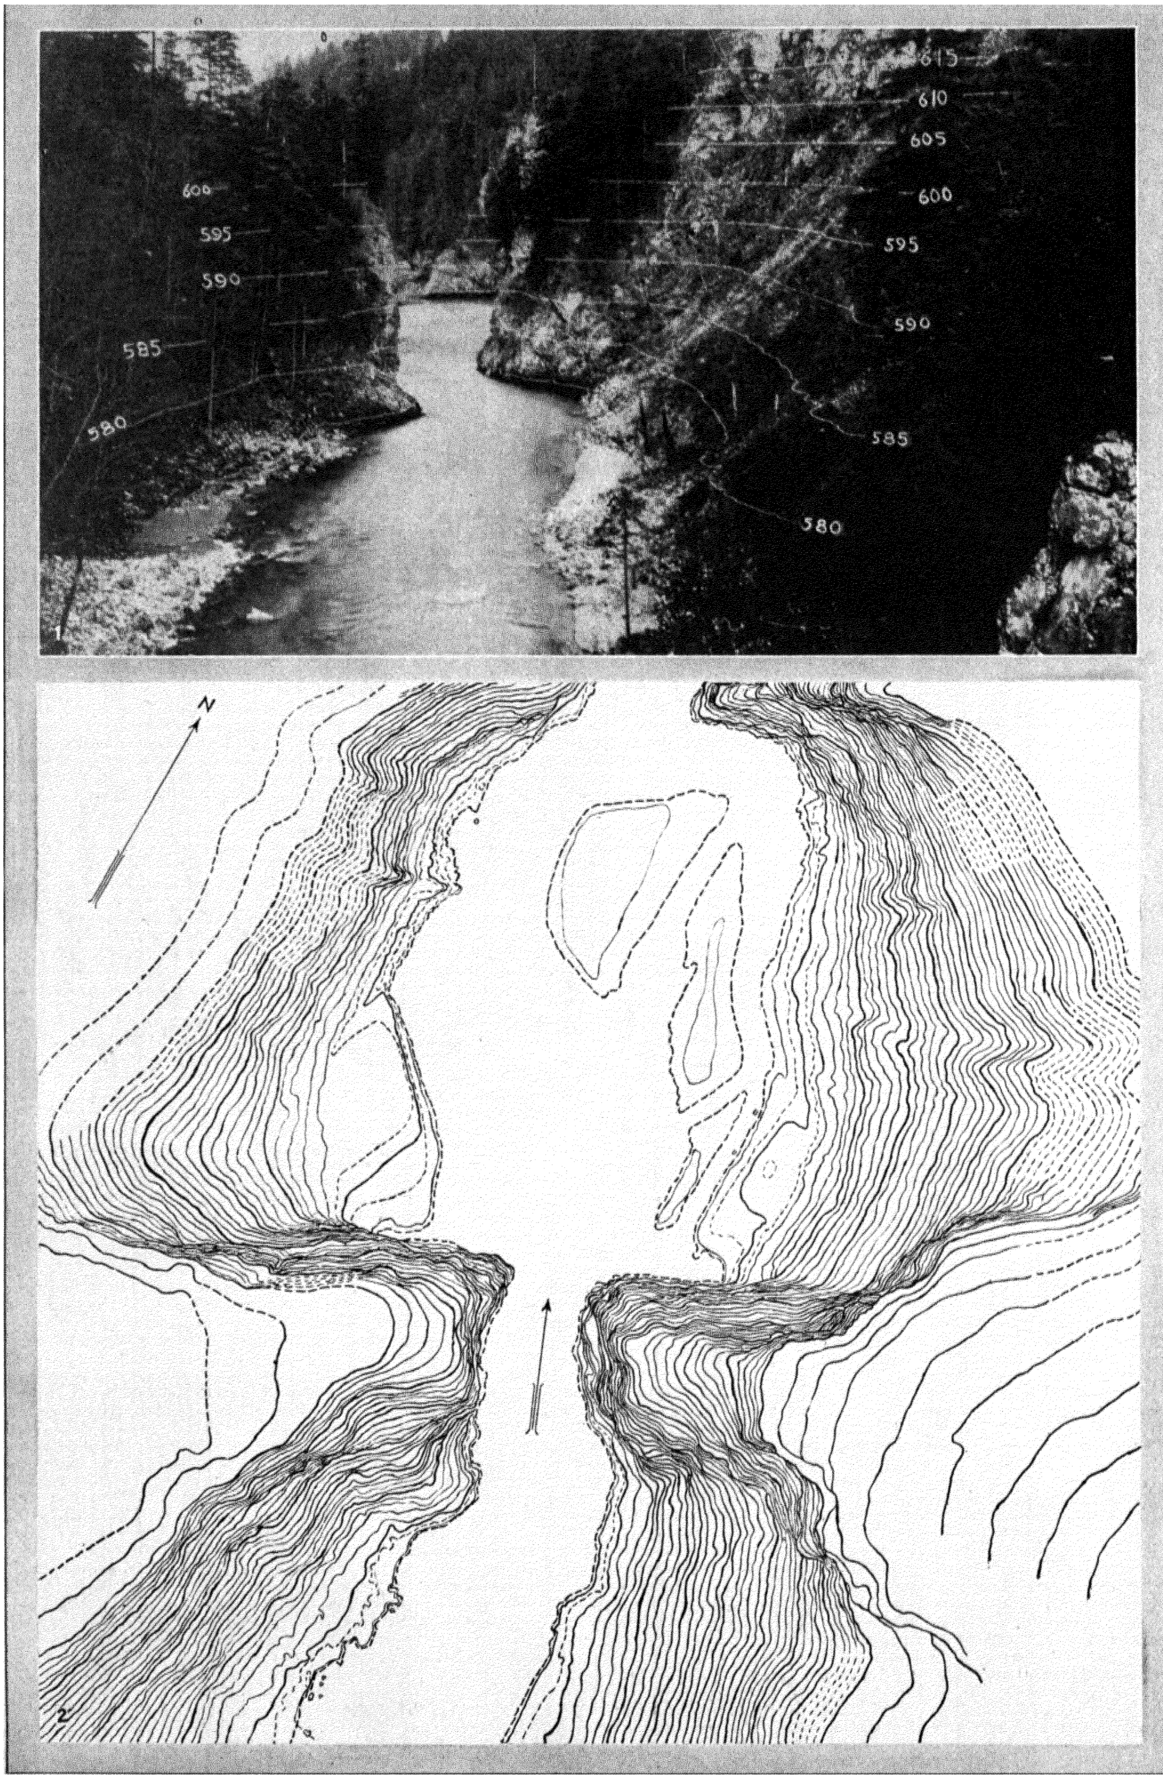
For the photography of ancient documents, T. Svedberg has made use of ultra-violet light, by means of which he has found it possible to decipher palimpsests.

Another application of photography to recording is that of the so-called "Factograph" camera. (*See* Plate III., fig. 3.) This camera includes a spool of sensitive paper on which the record can be made, a lens and lighting box being placed in front of it so that when the camera is pressed down on an object to be photographed lamps supplied by dry batteries will illuminate it and the object will be in focus on the paper. Perhaps the most important application of the Factograph camera is to the reading of telephone meters.

Another special device carrying out the same idea is that due

CAMERAS FOR SPECIAL TECHNICAL WORK

1. Hythe Gun Camera for training aviators in the use of the machine gun
2. Photostat Camera for the reproduction of documents
3. Factograph Camera for photographing meters
4. Zeiss Phototheodolite for surveying by photography
5. Autofocus Enlarger
6. Photograph of a wedge spectrum taken on plates sensitized with Dicyanine, Kryptocyanine and Neocyanine



PHOTOGRAPHY USED IN SURVEYING

One of a series of photographs taken with a phototheodolite, and a contour made from them

to G. L. McCarthy, who has designed a camera intended to photograph upon a strip of motion picture film all the checks passing through a bank. This camera, which is known as the "Recordak," provides a permanent record which greatly diminishes the risk of fraud.

Special cameras have also been designed for photographing the inside of rifle barrels in order to study the erosion of the bore, for lowering into oil wells in order to photograph the shaft, and for use with cystoscopes to photograph the interior of the body. All these cameras involve the optical principles of the periscope (*q.v.*).

An interesting application of photography is the so-called "gun camera" designed by the Royal Air Force in 1916 and used for the training of military aviators. (*See* Plate III., fig. 1.) With this camera, which resembled in shape a machine gun, an aviator in training engaged in mock combat photographed his adversary, and on development the film showed the accuracy of his aim. In later models a time record was included, so that it was possible in a mock duel to determine which of the two "shot" the other first.

The greatest application of photography is, however, to general recording. The use of photography for recording the movement of physical instruments is mentioned as early as 1876 in Tissandier's handbook of photography. As a rule, any physical instrument can be made to record photographically. Thus, a galvanometer reflects a beam of light by means of a mirror, the movements of which are controlled by the current in the instrument. If the light is allowed to fall on a photographic material which is moving, a record will be obtained. Convenient cameras for this purpose use plates allowed to fall at uniform rates or rotating drums covered with paper or film.

A very wide application of photographic recording is found in the oscillograph, which is used for many purposes in addition to its primary one of recording the wave form of intermittent or alternating electric currents.

The electrocardiograph is an oscillograph adapted to the recording of the very weak currents produced by the heart.

The applications of photographic recording are innumerable; its use for magnetographs and seismographs should, however, be mentioned. (*See* fig. 4.) When the mirror is attached to a diaphragm, sound can be recorded and analysed. (*See* MOTION PICTURES.)

In connection with science, photography is used (1) for recording visible images; (2) for integrating radiation over long periods; (3) for detecting invisible radiation; (4) for measuring the intensity of radiation. Classes 1 and 2 covering the recording of visible images whether for a long or a short time cannot, of course, be separated and cover between them by far the most important applications of photography.

Astronomical Photography.—One of the branches of science to which photography is of the greatest importance is astronomy. At the present time visual observation in astronomy has been replaced almost entirely by photography. A photographic plate is used in the focal plane of the telescope, and the observer's work is reduced to directing the telescope towards the object to be photographed and correcting any irregularities in the driving clock, which would produce a shift in the position of the image upon the plate.

In the case of reflecting telescopes, the photographic focus is, of course, identical with the visual focus, since mirror systems do not involve chromatic aberrations, and for this reason as well as because of their lower cost, all modern telescopes of the largest size are of the reflecting type. A certain number of refractors have been made with photographic correction of their lenses, but most of the large refractors are corrected only for visual rays, and with these photography is done on green, sensitive plates through a strong yellow filter, so that the record is made by green light.

Stellar positions are now determined entirely photographically, the micrometer eyepiece no longer being used. In this connection, the astrographic chart should be mentioned. (*See* ASTRONOMY.) A notable advance made possible by photography is the accurate determination of the parallaxes of the nearer stars. The number of stars observable has been greatly extended by photographic means, the 100 in. reflector at Mount Wilson recording stars of the twenty-first magnitude; that is, about one million times fainter than the faintest stars visible to the naked eye. And it may be confidently anticipated that the projected 200 inch reflector, when completed and used photographically, will make a proportionate increase.

Spectroscopy.—In spectroscopy (*q.v.*), visual observation has also been replaced by photography. The ease, indeed, with which the ultra-violet and violet parts of the spectrum could be photographed has led perhaps to an undue amount of attention being concentrated on those regions. The photography of the longer wave-lengths of the visible spectrum became possible only after the discovery of the isocyanine and carbocyanine dyes, at the beginning of the twentieth century. Dicyanine made possible the photography of the extreme red but has now been replaced by Kryptocyanine, while a new sensitizer, Neocyanine, makes possible photography in the near infra-red up to 900 $m\mu$. (*See* Plate III. fig. 6.)

In the ultra-violet, ordinary photographic plates are satisfactory down to 230 $m\mu$, but below this the absorption of the gelatine becomes serious. V. Schumann first investigated the short wave-length region from 120 $m\mu$ to 200 $m\mu$ by means of plates prepared with a minimum of gelatine. Recently, satisfactory photographs have been made in this region on ordinary plates sensitized with fluorescent bodies, such as paraffin oil.

Photomicrography.—The application of photography to

microscopy covers a wide range. Small cameras are fitted to ordinary visual microscopes and used to make records of value chiefly for reference. In a more elaborate apparatus, a camera on a stand is swung over the vertical microscope, but for serious photomicrography, it is usual for the camera and microscope to be mounted on large stands or preferably on one rigid optical bench together with the illuminating system.

Recently, special photomicrographic apparatus has been built, in which the ordinary microscope is replaced by a part of the optical bench itself, such apparatus being particularly designed for the photomicrography of metal specimens.

For many years, the highest powers of the microscope were used only for the examination of bacteria and of test objects, such as the minute structure of diatoms, but the demands of the metallurgists and of research bacteriologists are now reaching to the utmost limit of the resolving power of the microscope.

Since resolving power is limited by the wave-length of the light used, photomicrography with ultra-violet light is now of value. It was used with remarkable results by Barnard in his study of micro-organisms connected with cancer and is also being applied to the study of the minute structure of metallic alloys. Apparatus for this purpose designed by A. Köhler was introduced by Carl Zeiss in 1914.

In the photography of stained specimens the control of the colour of the light is of great importance, and for this purpose sets of light filters have been designed by means of which stains can be photographed by light exactly complementary to that which they transmit. The maximum contrast is thus obtained.

Phototopography.—Col. Laussedat of the French army was the pioneer in the application of photography to surveying, and since photographic surveying is more suitable for mountainous countries, it is in the Alpine regions of Europe and the mountain chains of Canada that the largest areas have been surveyed photographically. Dr. Deville, late surveyor-general of the Dominion of Canada, studied the subject very exhaustively and wrote a number of books on the subject, and the Russian surveyors have also used photographic methods on a large scale, especially in their surveys of Siberia.

In order to make a photographic survey, two photographs are taken of the same area from different known positions which are plotted on the map. Lines are then drawn from the positions to each identifiable point on the map and object in the photograph until the complete survey is accomplished, this plotting being done after the manner of a plane table survey but with the advantage that the detailed plotting is done in the office and is therefore independent of the weather, the only work done in the field being the photography. The cameras used for the purpose are of rigid construction and have levelling mounts so that they can be levelled precisely. Elaborate photo-theodolites have been devised for the purpose, notably a beautiful instrument designed by Zeiss, but simpler cameras are also quite satisfactory provided that they are rigidly made. (*See* Plate III. fig. 4.) No considerable area can, of course, be mapped without a skeleton of positions determined relatively to each other with precision, and the primary triangulation is therefore made over the area to be mapped, other points then being interpolated from the photographs.

Another method of photo-surveying is by the use of the principle of stereoscopy. Two photo-theodolites are put at the opposite ends of a measured base and exposures made in which the same objects are included. From the photographs distances can be measured by the use of the stereo-comparator designed and perfected by Prof. Pulfrich of the optical research establishment of Carl Zeiss at Jena. A notable advance in this field of stereoscopic photo-surveying was made when Captain von Orel of the Austrian army developed the stereo-autograph, which is a three-dimensional pantograph which can be used in conjunction with a stereo-comparator and will plot a map directly from the photographs. Stereo-photo-topography is now the most advanced of photographic methods of survey; its accuracy is high, and it is very rapid. Its drawbacks are the high cost of the instruments, the necessity for base measurement, which is not always easy, and the considerable weight to be transported. (*See* Plate IV.)

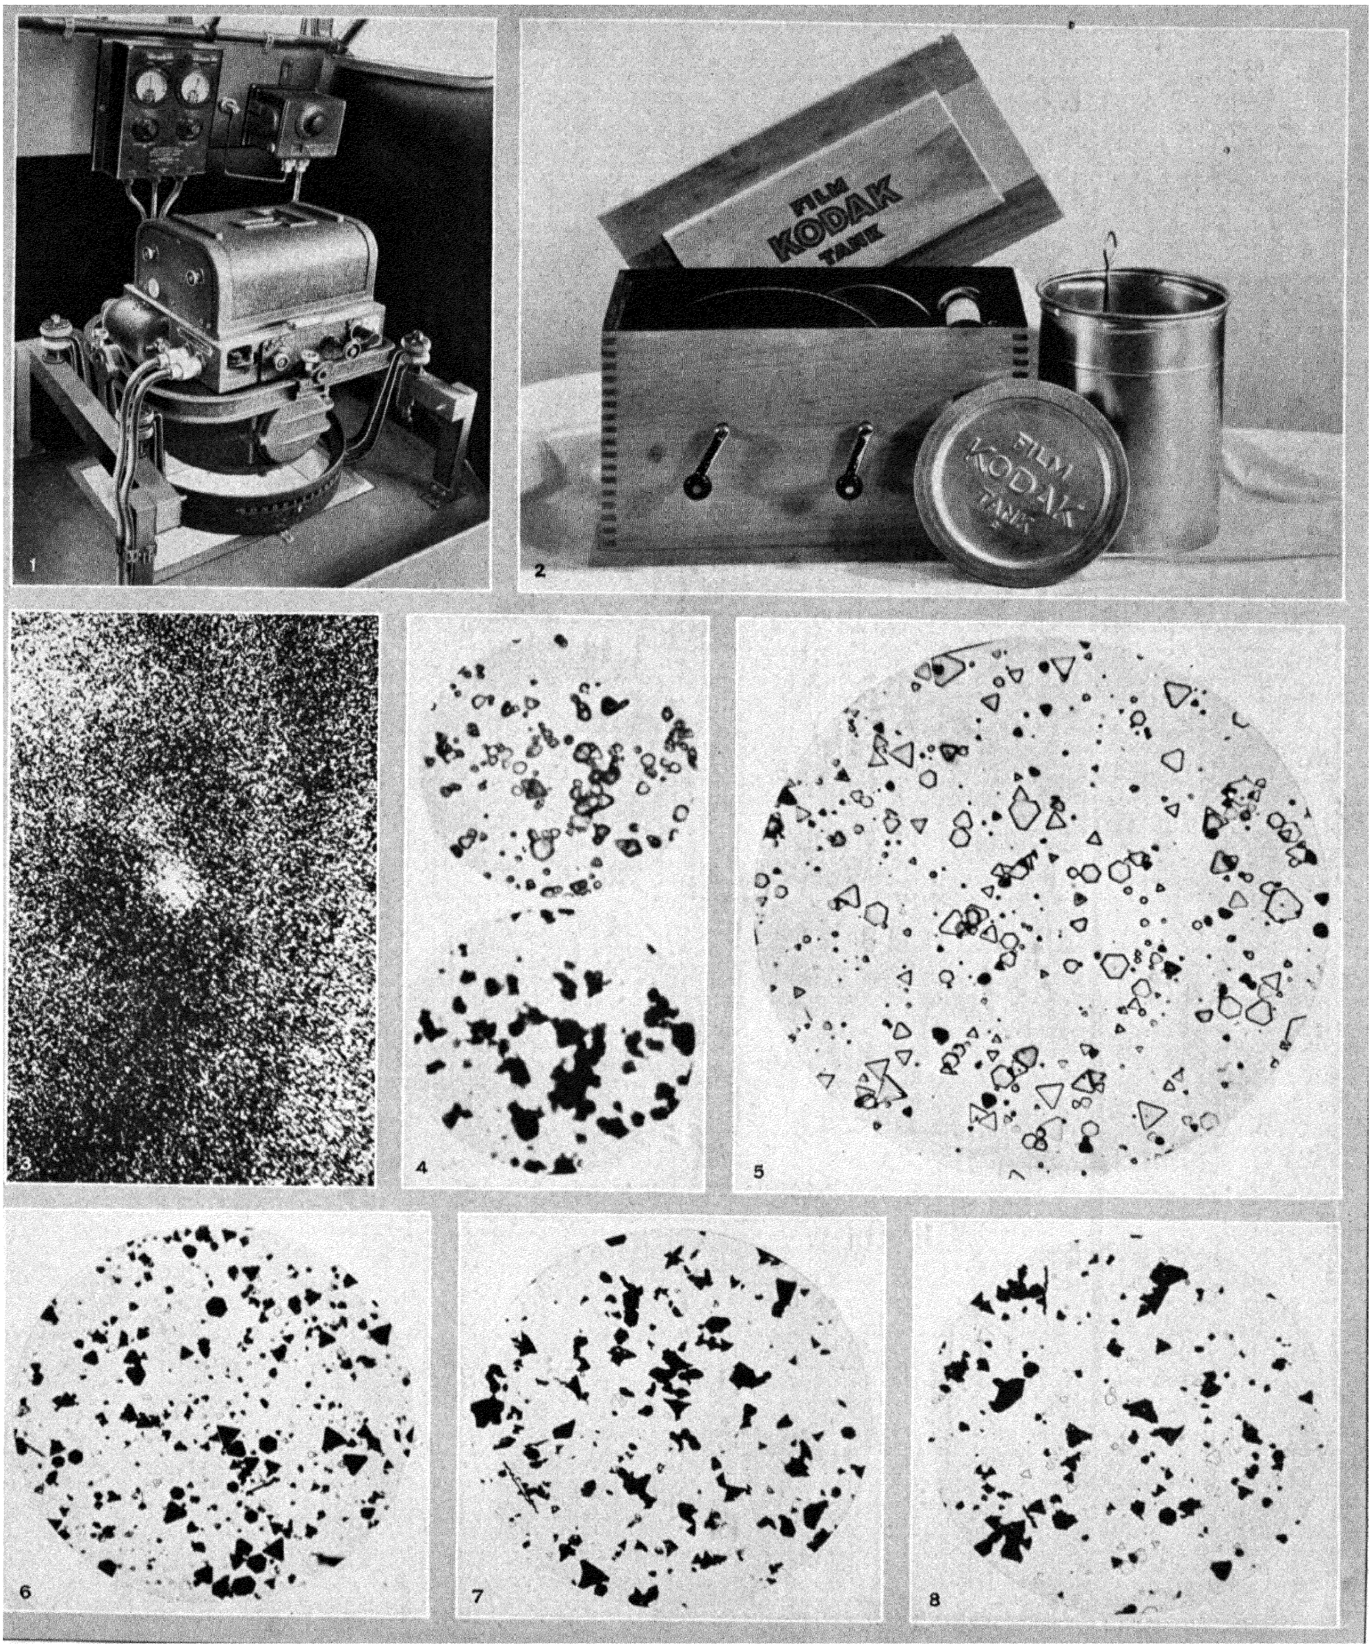
Aerial Photography.—Photography from the air is utilized for military purposes as well as for surveying. Its use during the World War was very extensive, thousands of negatives being taken every day by the armies. The first aeroplane cameras were modifications of standard cameras with usually a focal plane shutter, and the material was generally plates carried in holders and later in magazines adapted for quick changing. Hand-operated cameras using magazines were later developed and were used largely in 1916 and 1917. Later, semi-automatic plate cameras were designed in which the observer released the shutter while the mechanism operated the changing of the plates. In the last years of the war these cameras were made of very considerable size and weight, sometimes as many as 50 plates 18 cm. × 24 cm. in size being carried on a camera at one time. Towards the end of the war film cameras were developed carrying rolls of film giving 100 exposures 18×24 centimetres. The great advantage of such cameras is, of course, the light weight of the material used. In 1918 entirely automatic film cameras were made, the changing of the film and the exposure being carried out by means of a motor, either electrical or driven by the wind. (*See* Plate V. fig. 1.) Automatic film cameras are used almost exclusively in the United States while plate cameras—either automatic or hand-operated—are still employed by the European air services. But the general adoption of film cameras for aerial photography may be confidently expected, since with recent improvements their superiority is marked.

From the photographic point of view the most important phenomenon encountered when working from a great height, as in an aeroplane, is the scattering of the light by the atmosphere, an effect which is generally known as haze. Since this scattering is greater for shorter wave-lengths of light, it can be eliminated to a considerable extent by the removal of the blue light and by the use of only longer wave-lengths. In order to accomplish this, the materials used are generally sensitive to red light, and filters can be used with satisfactory results as to exposure; under such conditions great penetration through hazy atmosphere is possible. Excellent photographs have been taken from the greatest height which an aeroplane can attain.

While aerial photography is an immense aid to the military both for the detection of enemy operations and also for the preparation of maps, its application to precision surveying is subject to limitations. It is not possible to note with sufficient accuracy the height and angle of the aerial camera for a map to be made without correction for errors, and consequently aerial surveying requires the provision of bases of known position on the ground which can be included and used to scale and correct the photograph. This limits its use in surveying (*q.v.*) since such measured bases are not always available. Nevertheless there are many purposes for which aerial surveying is very well adapted. A fire survey of a city can be made with sufficient accuracy by aerial photography at less than one-tenth of the cost of a corresponding ground survey. This makes it possible to repeat the fire surveys of rapidly growing cities at much more frequent intervals than could be done otherwise. Surveys of lakes and forests can be carried out by the aeroplane rapidly and with sufficient accuracy for many different purposes. (*See* ARCHAEOLOGY; SURVEYING.)

Radiography. (*See* RADIOTHERAPY; RÖNTGEN RAYS.)—In this branch of photography very special conditions of work are involved. From its introduction in 1896, when X-rays were discovered by Röntgen, the field of radiography—almost entirely in connection with its medical application—has grown until at the present time approximately as many negatives are taken by means of X-rays as are made in portrait studies.

The earlier radiographs were made on plates of the same type as those used for portraiture; improvements were made by the introduction of large quantities of silver salt into the emulsion, while later attempts were made to load the emulsion by the addition of salts of other metals in such a way that the absorption of the X-rays would be increased and high sensitiveness obtained. There is reason to believe that these attempts were based on an incorrect understanding of the laws of the absorption of the



PHOTOGRAPHIC APPARATUS AND MATERIAL

2. Roll film developing tank
3. Grain structure of an image
4. Silver-bromide grains, before and after development
5. Crystalline grains of silver bromide in an emulsion
6. Silver grains produced by development with hydroquinone
7. Silver grains produced by development with metol
8. Silver grains produced by development with diaminophenol

X-rays. A considerable advance in the technique was made when double-coated film was introduced, a special X-ray emulsion being coated on both sides of the film, so that the image was formed half on the front and half on the back. It is customary to use such films in combination with one or more, generally two, so-called intensifying screens. These intensifying screens consist of a layer containing calcium tungstate coated on a suitable support. The calcium tungstate fluoresces under the influence of the X-rays, transforming a portion of the X-rays into light which is active photographically. The general method of working, therefore, is to expose the film in a cassette; that is, a holder in which the film is pressed into contact with an intensifying screen on each side.

One of the great difficulties in obtaining radiographs of good quality, especially when photographing through portions of the body of considerable thickness, is the presence of scattered radiation or secondary X-rays produced by the scattering of the primary X-rays in the tissues. Measurements have shown that the scattered radiation generally accounts for as much as three-fourths of the entire density of a radiograph taken through the body, and since this scattered radiation does not contribute to the formation of the image, it naturally produces a great lowering of contrast and general loss of detail and quality. The best method of eliminating this is the use of what is known as the "Potter-Bucky" diaphragm, which consists of a grid formed of strips of lead foil pointing toward the source of the X-rays. This diaphragm is placed between the subject photographed and the film. In order to prevent its forming shadows, the diaphragm is moved during exposure, and under these conditions the strips of lead cut out much of the scattered radiation, which is not proceeding from the source of X-rays but is scattered in all directions, and thus enable the image to be formed to a much greater extent by the direct X-rays coming from the focal point (*See* fig 5)

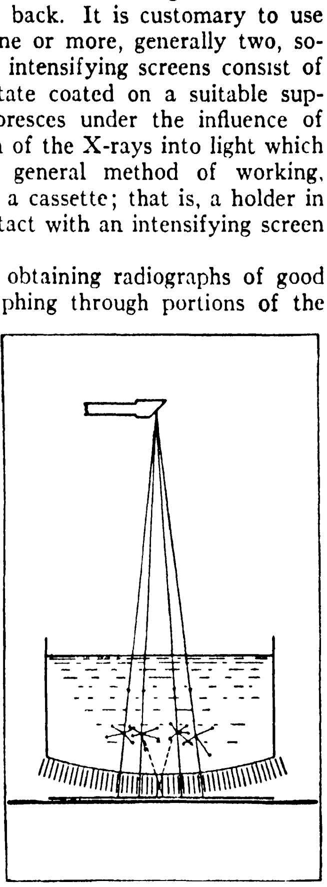

FIG. 5 —DIAGRAM SHOWING USE OF POTTER-BUCKY DIAPHRAGM

For dental work the film is supplied in special packages to be held inside the mouth usually with a backing of lead foil to stop secondary radiation and to enable the package to be moulded to the shape of the mouth Dental radiography has been extended very rapidly, and radiographs of the teeth are among the most valuable guides to the operations of the dental surgeon

(C E. K. M.)

THEORY OF PHOTOGRAPHY

The Sensitive Material.—If a photographic negative be examined under a microscope, it will be seen to consist not of a continuous homogeneous surface but of discrete, small silver grains occurring chiefly in clumps. (*See* Plate V., fig. 4.) These silver grains are derived from the structure of the original sensitive emulsion. This is shown in Plate V., fig. 3, where we see that the developed grains correspond in general form and position to the undeveloped silver bromide grains from which they were produced.

If the emulsion is removed from a sensitive film and spread out under a microscope in a thin layer, it will be seen that the silver bromide is in the form of crystals, these being usually flat crystals, generally hexagonal or triangular in shape. (*See* Plate V., fig. 5). These crystals are very small, $\frac{1}{10,000}$ in or less across; there are great numbers of them in a film, several thousand million in a square inch, and their size depends upon the way in which the emulsion was made.

If an emulsion is made by adding a solution of silver nitrate to one of bromide in the absence of gelatine, the silver bromide formed will settle out in coarse flocks, but if a small quantity of gelatine be added to the solution, the silver bromide will be precipitated in a much finer form and will remain in suspension. In making an emulsion, therefore, gelatine is added to the bromide solution, and the mixture is brought to the proper temperature, then the silver nitrate solution is added, and the whole is heated.

When first mixed, the emulsion by transmitted light appears of a deep ruby colour. As heating is continued, the colour changes, becoming finally a bluish gray. Examination of the precipitate by means of X-rays has shown that the silver halide is crystalline from the beginning, the changes in colour and absorption being due merely to an increase in the size of the crystals. As this increase in size proceeds, the emulsion gains in sensitivity, but the chief increase in sensitivity occurs after the bulk of the gelatine has been added After the emulsion is set it is cut up by squeezing it through a sieve and then washed to remove the soluble salts. It is then further ripened to obtain the sensitiveness required

The sensitiveness obtained depends to a very large extent upon the particular kind of gelatine used, some gelatine giving high sensitiveness, while other samples, apparently of the same chemical and physical properties, will not give good sensitiveness however long the heating is continued As will be shown later, this has been found to be due to a small impurity carried in the gelatine

The crystals in an emulsion vary very greatly in size, their size and distribution being controlled by the conditions under which the emulsion was precipitated and digested. The sizes of grains which occur in an emulsion are directly connected with photographic properties of that emulsion

When the grains cover a wide range of sizes, the emulsion is suitable for making negatives; it usually has a high degree of sensitiveness and a low degree of contrast When, on the other hand, the grains are small and uniform, the emulsion has a high degree of contrast and a lower sensitiveness, such emulsions being used for positive film or lantern slide making

If we suppose that the same amount of photo-chemical product (latent image) makes either a large or a small grain developable, then, other things being equal, the larger grain contributes a larger amount of silver to the image and thus gives more density for the same amount of light action than a smaller grain For this reason alone, emulsions containing large grains would be more sensitive than those containing small grains, but experiment has shown that this is not the only factor and that larger grains require less light action to become developable than small grains Further, it has been shown that the seat of this sensitiveness is concentrated in specks in the grains, and the sensitiveness of the grain depends upon the presence and the number of these sensitive specks

Being different in nature from the silver bromide itself, it was suspected that the specks were derived from the gelatine, since some gelatines give emulsions which are much more sensitive than others A material was extracted from gelatine which was identified by Dr S E Sheppard with allyl mustard oil, which in ammoniacal solution becomes allyl thiocarbamide. Allyl thiocarbamide reacts with silver bromide, and the compound of the two in alkaline solution produces silver sulphide, so that the sensitizing specks may be ascribed to the presence of minute traces of silver sulphide on the surface of the silver bromide grain The ripening process characteristic of the preparation of gelatine bromide emulsions may therefore be ascribed partly to the development of grains of larger sizes from those of small dimensions and partly to the production of the sensitizing specks of silver sulphide on the surface of the grain.

The exact action of light upon the silver halide and the nature of the product which renders the grains developable is not well understood, although recent work is tending to define the issue and to suggest that we are not far from the complete solution of the problem. The exposed silver halide, which changes to silver in development, is known in photography as the "latent image," and the problem of the nature of the latent image has been a

subject of speculation from the earliest days of the science.

The theories put forward as to the nature of the latent image may be roughly divided into chemical and physical:

The physical theories include theories of disintegration and of depolymerization as well as theories of the formation of the image without involving any assumption as to its actual nature, such as the theories of molecular strain and of photo-electric emission of electrons.

The latent image has certain definite chemical properties. It is normally stable, since it has been known to persist for many years. Its fundamental property is that of facilitating the deposition of silver in a reducing agent, such as a developer. It can be destroyed by powerful oxidizing agents, such as chromic acid or acid permanganate. These properties seem to call for the existence of some definite chemical individual, and it would appear, therefore, that the latent image must consist of some reduction product of silver bromide. Those which have been suggested are silver sub-bromide and metallic silver.

The existence of silver sub-bromide is doubtful; the formula $AgBr_2$ has been proposed but it has never been prepared in a pure state. All attempts to prepare it have resulted in mixtures or solid solutions of silver bromide with metallic silver. While the theory that silver sub-bromide was the material of the latent image was accepted for many years, it is now generally agreed that the image consists of metallic silver in very small amounts formed by the reduction of silver bromide.

When light falls upon a crystal of silver bromide, therefore, it produces a small quantity (perhaps a few hundred or a few thousand atoms) of silver, and provided this speck of silver is of sufficient size it will act as a nucleus and will render the crystal developable. The production of the silver appears to be greatly facilitated by the existence on the crystal of small specks of foreign material, presumably, from Sheppard's work, silver sulphide. The mechanism of this action is still under discussion.

Dr. Sheppard and his colleagues have developed a theory which they term the "concentration speck theory," according to which the action of the sensitizing speck is to concentrate the energy falling upon the silver bromide and enable silver to be liberated at the boundary of the speck.

F. C. Toy and A. P. H. Trivelli have suggested independently that the chief action of light is to increase the conductivity of the silver bromide, and Trivelli suggests that an electrolytic action then ensues as a result of which metallic silver is deposited in contact with the silver sulphide speck.

K. C. D. Hickman and others have postulated that a sensitizing speck must be an acceptor for the halogen set free, and many mechanisms have been suggested for the reaction.

Development.—In the process of development, the bromine is removed from the crystals of silver bromide, which are transformed into coke-like masses of metallic silver. With some developers, the silver takes the form of the silver bromide grains, while with others the grain is entirely broken up and distorted and is merely replaced by an equivalent amount of metallic silver. (*See* Plate V., figs. 6, 7, 9.) There are many chemicals which will reduce silver bromide to silver, but in order to act as a developer it is necessary that the solution should have the power of turning exposed silver bromide into metallic silver and should not be able to act on unexposed silver bromide, since if the solution acted on the unexposed as well as the exposed grains, the whole film would darken, and we should not get an image at all. Only a very limited number of substances have the power of distinguishing between exposed and unexposed grains of silver bromide, and there are therefore only a few substances which are suitable for use as developers. With the exception of ferrous oxalate and one or two other inorganic compounds which have fallen into disuse, all the developing agents used are phenolic or amino compounds derived from benzene or naphthalene.

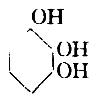
The chief developing substances are pyrogallol, or *pyro* as the photographer calls it; hydroquinone; and methylparaminophenol, which is known under trade names such as "metol" and "elon." All of these developing substances are chemically related to benzene.

It was shown by Lumière and Seyewetz and by Andresen that in order to be practically useful developers must contain at least two hydroxyl groups or two amino groups or one hydroxyl and one amino group attached to the benzene nucleus in the para or ortho position; meta compounds have no developing power.

The three developing agents chiefly used are thus hydroquinone,

which is para-dihydroxybenzene and is made by the oxidation of aniline and the reduction of the quinone formed; metol or methylparaminophenol,

which can be produced by the methylation of paraminophenol or by various other less direct reactions; and pyrogallol, trihydroxybenzene,

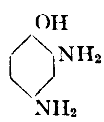


which is produced by the distillation of gallic acid.

In addition to these three, there are a large number of similar compounds which can be used as developing agents and for which advantages are sometimes claimed. In all probability, however, the three compounds given above will supply all the needs of the photographer.

Two compounds which have some wide use, however, are paraminophenol,

which is intermediate in its properties between methylparaminophenol and hydroquinone; and diaminophenol, or amidol, which is used for the development of papers.



With the exception of diaminophenol, these compounds are unable to reduce silver bromide in neutral or acid solution, and in order to make a developing solution, alkali must be added to the solution of the developing agent. In the case of the aminophenols the developing agents are used in the form of salts of the bases; thus, metol is the sulphate of paraminophenol, and it is usual to employ the chloride of paraminophenol and of diaminophenol. Enough alkali must therefore be added initially to liberate the base itself, which is usually insoluble in water, and to redissolve it as the alkaline phenolate. The most convenient alkali is sodium carbonate, and a typical developer would thus consist of pyrogallol with sodium carbonate added to it. As is well known, however, alkaline pyrogallol absorbs oxygen from the air very rapidly and would soon darken and lose its developing power. In order to make the developer keep, a small quantity of sodium sulphite is added to the solution. The sulphite protects the developer from oxidation and thereby enables it to retain its full developing power, although the sulphite, when used alone, possesses no developing power whatever.

The essential constituents of a developer, therefore, are the developing agent—pyro or hydroquinone or metol; the alkali, which is generally sodium carbonate; and the preservative, which is sodium sulphite. In addition, it is usual to add a small amount of alkaline bromide, which will act as a restrainer and prevent

the development of unexposed silver bromide, giving rise to what is known as "fog."

The various developing agents behave somewhat differently. Suppose, for instance, that we make up two developers, one with hydroquinone and the other with metol, and start to develop a film in each at the same time. In the metol developer the image will appear very quickly, and will appear all over the film at the same time, the less exposed portions which, of course, were the shadows in the picture, appearing at the same time as the highlights. On the other hand, with the hydroquinone the image will appear more slowly, and the most exposed portions, or the highlights, will appear first, so that by the time the shadows have appeared on the surface of the film the highlights will have acquired considerable density If development is stopped as soon as the whole image is out, the negative developed in metol will be very thin and grey all over, while that developed in hydroquinone will have a good deal of density in the highlights. Thus, of these two developers we may say that metol gives detail first and then slowly builds up density, while with hydroquinone the detail comes only after considerable density has been acquired It is for this reason that these two developing agents are used in combination; the hydroquinone gives the density and the metol the detail, and together they make a satisfactory developer.

These differences in the behaviour of developing agents are due to a property of the developer which is commonly known in photography as the *reduction potential*

The reaction of development may be represented by the following general equation:—

$$NaR + AgBr \rightleftharpoons Ag + NaBr + R'$$

The sodium salt of the reducing agent symbolized by R reacts with silver bromide and forms metallic silver, the oxidation product of the developing agent, which is symbolized by R′, and sodium bromide

The reaction will go in either direction according to the driving force available, and, in practice, quinone, the oxidation product of hydroquinone, together with sodium bromide, will bleach a silver negative, transforming the metallic silver into silver bromide. Now, the driving force in the direction from left to right depends upon the reduction potential of the developer. This is opposed by the reaction in the opposite direction, which is dependent on the concentration of soluble bromide and of developer oxidation product in the solution, so that if the bromide be increased, the rate of the reaction will be lowered It is thus possible to measure the reduction potential of a developer by the effect of potassium bromide on development, as was originally suggested by S E Sheppard A careful study of this was carried out by A H Nietz, who gives what are probably the most reliable data for the developers as follows —

Developer	Relative energy
Ferrous oxalate	0·3
p phenylene diamine hydrochloride (no alkali)	0·3
p-phenylene diamine hydrochloride (alkali)	0·4
Hydroquinone (standard) .	1·0
p-phenylglycine	1·6
Hydroxylamine	2·0
Toluhydroquinone	2·2
p-aminophenol (hydrochloride)	6·0
Chlorhydroquinone	7·0
Dimethyl p-aminophenol (sulphate)	10·0
Monomethyl-p-aminophenol (sulphate)	20·0
Diaminophenol	30–40

The most widely used developer for negative making is pyrogallol Owing to the fact that the pyro is changed during development into a substance having a yellow colour, some of which remains associated with the silver in the image, pyro tends to give a slightly yellowish or brownish image, which has very much greater printing power than the plain silver image. The yellowish stain is prevented from forming by sulphite, so that the more sulphite there is in a developer, the less colour the deposit will show. Pyro is, therefore, used only for the development of negatives, prints on paper or positive films in motion picture work being developed with metol and hydroquinone.

When a film is developed, it is only the grains of silver bromide which have been changed by the action of light that are affected by the developer. The grains that have not been changed are not affected.

At the beginning of development, there are a great many exposed grains ready to be developed, and then as development

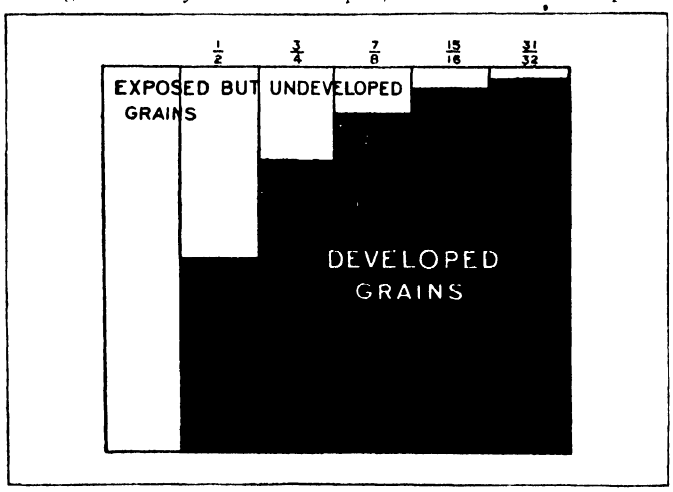


FIG 6.—DEVELOPMENT OF EXPOSED GRAINS IN A FILM WHICH IS HALF DEVELOPED IN ONE MINUTE

1st column, at beginning; 2nd, after 1 minute; 3rd, after 2 minutes; 4th, after 3 minutes; 5th, after 4 minutes; 6th, after 5 minutes

proceeds, these exposed grains are turned into grains of black silver, so that the number of developable grains decreases during development until at last there are no developable grains left, all those which can be developed have been acted upon, and the development of the image ceases The rate at which the grains develop depends upon the number of exposed but undeveloped grains left, and as the grains are developed and the number of undeveloped grains remaining becomes less, fewer and fewer grains develop in each minute, until finally it is not worth while to prolong the development in order to get any more density. (*See* fig. 6)

The growth of the image during development is referred to as a growth of density; that is to say, the density is a measure of the number of grains of silver which are produced at any given point because these grains of silver, after the film has been cleared by the fixing bath, obstruct the passage of light through the film

The density of an image is measured in units which are based on the amount of silver which will let through $\frac{1}{10}$ of the light, so that if only $\frac{1}{10}$ of the light falling on the negative gets through a certain part of it, that portion of the negative is said to have a density of 1 Similarly, when only $\frac{1}{100}$ of the light incident is transmitted, that part of the negative is said to have a density of 2 The blackest part of a negative may have a density of perhaps 2, the middle tones 1 or less, and the shadows, perhaps $\frac{1}{10}$ (*See* fig 7)

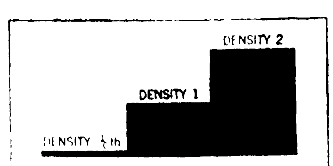

FIG 7—DENSITIES OF VARIOUS PARTS OF A NEGATIVE

1st division, shadows; 2nd, halftones; 3rd, highlights

The difference of density between the darkest portion and the lightest portion of the negative is called its *contrast*

Since the contrast depends chiefly upon the density of the highlights, it grows during development just as the density does (*See* fig. 8.) It grows rapidly at first, when there are many grains to be developed, and then more slowly until, finally, when the exposed grains are all developed, the negative will not give any more contrast however long development may be prolonged, and a continuation of development will result only in the production of fog The final contrast which can be obtained depends upon the kind of emulsion used. The fast emulsions, such as the negative emulsions, give moderate contrast, but the slow emulsions,

such as those used for copying purposes or for making lantern slides, are especially made to give great contrast when development is prolonged. (*See* fig. 9.)

The temperature coefficient of development is about 2 for 15° F, although it varies somewhat with the developer. Thus, if the development time at 65° be 4 min., it will be about 2 min. at 80° F, and about 8 min. at 50° F. Tables and curves showing

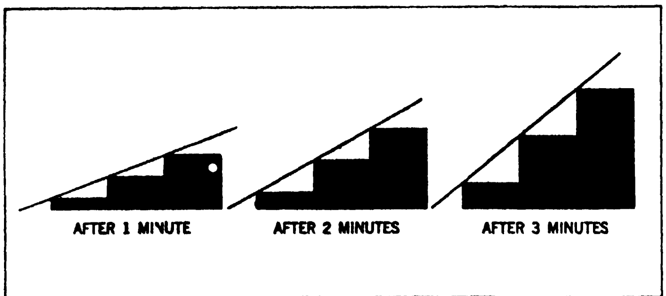

FIG. 8.—THE GROWTH OF CONTRAST DURING DEVELOPMENT

the relation between the time of development and the temperature are in common use in photography (fig. 10), which shows a curve supplied for use of X-ray workers giving the time of development for a standard developer at various temperatures.

After Processes.—After development, the undeveloped silver bromide is removed by immersion of the negative or print in what is called the "fixing" bath. There are only a few substances which will dissolve silver bromide, and the one which is universally used in modern photography is sodium thiosulphate, $Na_2S_2O_3$, which is known to photographers as hyposulphite of soda, or more usually as "hypo"—the name hyposulphite of soda being used by chemists for another substance.

Wet collodion plates were fixed by means of cyanide, which is a very active solvent for silver halides, but its poisonous nature and its tendency to attack the image has led to its disuse with gelatine plates. Sodium thiosulphate dissolves silver iodide only very slowly, and cyanide is therefore still used by photo-engravers who use the wet collodion process.

If free acid is added to a solution of thiosulphate, it is decomposed and sulphur is precipitated. This can, however, be prevented by the addition of sulphite. An acid fixing bath, therefore, is preserved, from decomposition, by sulphite which also serves to prevent the oxidation of developer carried over into it. The developer which is carried over into the fixing bath is, however, alkaline, and consequently a considerable amount of acid is required in a fixing bath which is used for any length of time, since if only a small amount is present, it will soon be neutralized by the developer carried over. For this reason the acids used in a

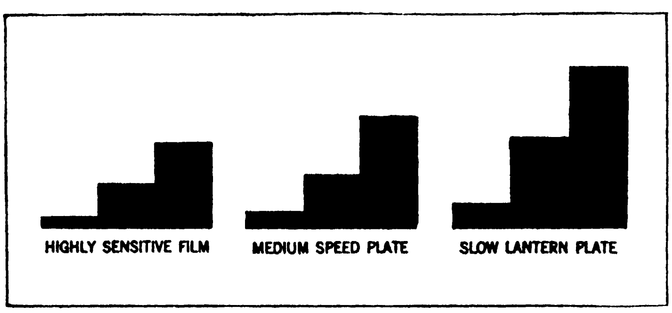

FIG. 9.—THE GREATEST CONTRAST WITH DIFFERENT EMULSIONS

fixing bath are those which are "weak," so that a large amount of acid can be added without raising the acidity of the bath to a level at which sulphur is precipitated; the best acid for the purpose is acetic acid. The commonest hardening agent is potash alum, and a typical fixing bath therefore contains 20% to 30% of its weight of hypo, about 1% of anhydrous sodium sulphite and of potassium alum, and 3% of 28% acetic acid.

The rate of fixing depends upon the concentration of the hypo and on the temperature. It increases to a maximum with about 40% hypo and decreases with stronger solutions owing to a decrease of the swelling of the gelatine and consequent difficulty of penetration.

A very important operation in photography is the washing of the negatives and prints in order to remove from them the chemicals of the fixing bath. If an exhausted fixing bath has been used, silver compounds will be present during washing, and it is most important that they should be removed by complete fixation.

The rate of washing depends largely upon the rate of diffusion of hypo out of the film into the water, provided the water in contact with the material is continuously removed. In washing,

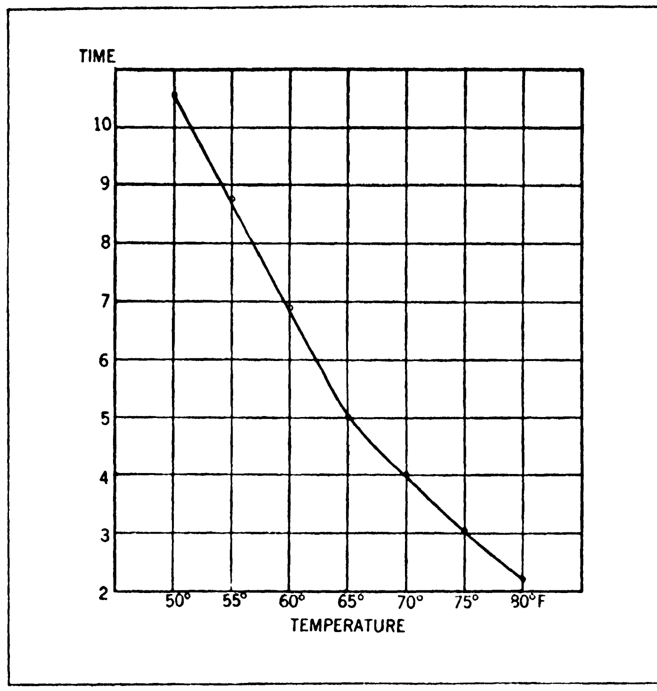

FIG. 10.—GRAPH SHOWING TIME OF DEVELOPMENT FOR X-RAY FILM AT VARIOUS TEMPERATURES

the amount of hypo remaining in the gelatine is continually halved in the same period of time as the washing proceeds. An average negative, for instance, will give up half its hypo in two minutes, so that at the end of 2 min., half the hypo will be remaining in it; after 4 min., one-quarter; after 6 min., one-eighth; after 8 min., one-sixteenth; 10 min., one-thirty-second, etc. It will be seen that in a short time the amount of hypo remaining will be infinitesimal. This, however, assumes that the negative is continually exposed to fresh water, which is the most important matter in arranging the washing of either negatives or prints.

Reduction.—When a negative is too dense, it is sometimes *reduced.* By reduction in photography is meant the removal of some silver from the image so as to produce a less intense image. Thus, in the case of an over-developed plate there will be too much density and contrast, and the negative may be reduced to lessen this. In the case of an overexposed negative there may not be an excess of contrast but the negative will be too dense all over, and in this case what is required is the removal of the excess density.

All the photographic reducers are oxidizing agents, and almost any strong oxidizing agent will act as a photographic reducer and will remove silver, but various oxidizing agents behave differently in respect to the highlights and shadows of the image. Reducing solutions can be placed in three classes:—

A. Cutting reducers
B. True scale reducers
C. Flattening reducers.

A. The cutting reducers remove an equal amount of silver from all parts of the image and consequently remove a larger proportion of the image from the shadows than from the highlights of the negative. The typical cutting reducer is that known as "Farmer's" reducer. This consists of a mixture of potassium ferricyanide and hypo, the potassium ferricyanide oxidizing the

silver to silver ferrocyanide and the hypo dissolving the latter compound.

Another cutting reducer is permanganate. The permanganates are very strong oxidizing agents, and if a solution of permanganate containing sulphuric acid is applied to a negative, it will oxidize the silver to silver sulphate, which is sufficiently soluble in water to be dissolved.

B. Proportional reducers are those which act on all parts of the negative in proportion to the amount of silver present; hence they exactly undo the action of development, since during development the density of all parts of the negative increases proportionally. A correctly exposed but over-developed negative should be reduced with a proportional reducer Unfortunately, there are no single substances which form exactly proportional reducers, but by mixing permanganate, which is a slightly cutting reducer, with persulphate, which is a flattening reducer, a proportional reducer may be obtained

C. In order to have a flattening reducer, we require one which acts very much more on the heavy deposits than on the light deposits of the negative and which will consequently reduce the highlights without affecting the detail in the shadows Only one such reducer is known, and this is ammonium persulphate Ammonium persulphate is a powerful oxidizing agent and attacks the silver of the negative, transforming it into silver sulphate, which dissolves in the solution It must be used in an acid solution and is somewhat uncertain in its behaviour, occasionally refusing to act, and always acting more rapidly in measure as the reduction progresses

Intensification.—Intensification is photographically the opposite of reduction, the object being to increase contrast This is done by the deposition of some other material on the silver image A silver image, for instance, can be very much intensified by toning it with uranium, the reddish-brown uranium ferrocyanide having very great printing strength and converting a weak negative into one having a great effective contrast for printing purposes Usually, however, intensification is performed by depositing a silver, mercury, or chromium compound upon the image, and many photographic intensifiers depend upon the use of mercury Experience has shown that mercury intensified images are not usually as stable as images produced by chromium intensification

The mercuric intensifier consists of a solution of mercuric chloride, a few drops of ammonium chloride or hydrochloric acid being added to the solution When the silver image is placed in this, it reacts with the mercuric chloride and forms a mixture of silver chloride and mercurous chloride The bleached image, which appears white, can then be treated in various ways If it is developed, for instance, both the silver chloride and the mercurous chloride will be reduced to the metal and to every part of silver there will be added an equal part of mercury Instead of using a developer, the image may be blackened with ammonia, which forms a black mercury-ammonium complex and produces a high degree of intensification

A very powerful method of intensification, used chiefly for negatives made by photo-engravers, is obtained by bleaching with mercuric chloride and blackening with silver dissolved in potassium cyanide The use of the cyanide cuts the shadows very slightly at the same time that the highlights are intensified, so that a great increase in the contrast of the negative is obtained This is usually known as the *Monckhoven* intensifier

In the case of the chromium intensifier the silver image is bleached with a solution of bichromate containing a very little hydrochloric acid, bichromate being an oxidizer of the same type as permanganate or ferricyanide The image is then re-developed and will be found to be intensified by the deposition of a chromium compound. This intensifier has found increasing favour owing to the ease and certainty of its operation and the permanency of the intensified image.

Sensitometry.—The first quantitative measurements of the result of the action of light on photographic materials were made by Sir W. de W. (then Captain) Abney in 1874. (Abney, *Phil. Mag.*, 48, pp 161–165, 1874) He constructed an instrument by which the transparency of the developed image could be measured, and by means of this he demonstrated that within limits the transparency of the deposit varied inversely as the logarithm of the exposure.

In 1890, F. Hurter and V. C. Driffield (*Jour. Soc. Chem. Industry*, vol ix, p. 455, May 7, 1890) published a classic paper entitled "Photo-Chemical Investigations and a New Method of Determination of the Sensitiveness of Photographic Plates," in which they studied systematically the relation between exposure, development, and the deposit of silver produced in the photographic process They first defined the photographic density D as being the logarithm of 1/transparency, or the logarithm of the opacity, which was defined as the inverse of the transparency.

Thus, if we have a light of intensity I incident upon a photographic deposit, and I' is transmitted,

$$T \text{ (the transparency)} = I'/I,$$
$$O \text{ (the opacity)} = I/I' = 1/T,$$
and
$$D = \text{density} = \text{logarithm of } I/I' \text{ or } -\log I'/I.$$

Hurter and Driffield showed experimentally that the density D of a given silver deposit was proportional to the mass of silver per unit area contained in the deposit This result was confirmed by J M Eder and by Sheppard and Mees, but it has recently been shown by Sheppard and Ballard that the relation is only approximate and that there may be considerable departures from true proportionality with variations of exposure and development A deposit transmitting approximately one-tenth of the incident light, that is, having a density of 1, is given by about 1/10 mg of silver per square centimetre of the film The following table of relations between density and transmission will be convenient:

Density	Transmission	Density	Transmission
0·0	1	1	1/10
·3	½	1 3	1/20
·6	¼	2	1/100
·9	⅛	3	1/1000

Basing their studies on their definition of density, Hurter and Driffield exposed photographic plates for definite times to a standard candle by means of a rotating wheel with cut-out sectors of various angles The plates were developed in a non-bromided developer, fixed, washed, dried, and the densities plotted on a

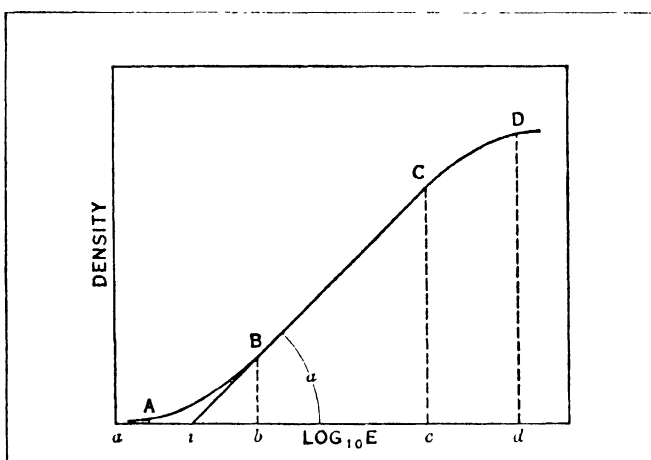

FIG 11 – CHARACTERISTIC CURVE OF AN EMULSION

chart with the logarithms of the exposure time as abscissae and densities as ordinates, as is shown in the accompanying diagram (*See* fig 11.)

This shows what is known as the characteristic curve of an emulsion There are three fairly well defined regions of the curve. Thus, from A to B we have the initial part convex to the log E axis, which may be termed the region of "underexposure"; between B and C, known as the period of "correct exposure," the increase of density is practically constant for each increase of exposure, being arithmetical for each geometric increase of

exposure; in the third region, from C to D, this arithmetical increase fails until the density becomes constant; this is the region of overexposure.

By prolongation of the straight-line portion of the curve, the log E axis is cut at a point which Hurter and Driffield termed the "inertia," which, when divided into a factor, gives the "speed" of the plate.

Hurter and Driffield adopted the factor 34 and provided that the "inertia" should be expressed in "candle-metre-seconds"; that is, seconds of exposure at one metre distance to one British standard spermaceti candle. The speeds so obtained were applicable to an exposure meter called the "Actinograph," which they designed. It is common in England to publish so-called "H. and D." speeds for photographic materials. Such speeds are not, however, always determined in accordance with the specifications of Hurter and Driffield, and the standardization of sensitometric matters has been much discussed, especially at the International Congresses of Photography held in Paris in 1925 and in London in 1928.

The spermaceti candle being quite obsolete as a standard light source, the character of the source to be adopted is of great importance, since its photographic effect will depend upon its colour. One candle power of daylight has more than ten times the photographic effect of one candle power of light from a spermaceti candle.

As most plates are exposed to daylight, it might be assumed that this should be the standard adopted; but the practical difficulties of ensuring a constant illumination of constant spectral composition are insuperable. The standard candle is notably poor in ultra-violet, violet, and blue radiations, being distinctly yellow in colour. The same objection applies to the Hefner-Alteneck amyl acetate lamp, which is used in Germany as standard. It is impossible to examine in detail all light sources suggested, but it is probable that eventually a lamp standardized to work at a colour temperature of 2,360° K with colour filters to reduce its spectral composition to sunlight will be taken as the standard. The spectral composition of the light is all important in view of the ever-increasing employment of colour-sensitive materials.

As was shown originally by Abney, an intermittent exposure does not give the same effect as a continuous exposure for the same total time. The use of the rotating sector is, therefore, undesirable, and instruments giving continuous exposures should be used.

Another important factor is the failure of the reciprocity law, $E=It$. As was first shown by Abney (*Proc. Royal Soc.*, 54, pp

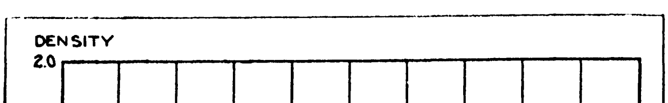

FIG. 12.—GRAPH SHOWING RELATION BETWEEN DENSITY AND INTENSITY, *It* BEING CONSTANT

143–147, 1894), the effect of an exposure is not independent of the intensity. Recent work has shown that the curve showing the relation between density and intensity, It being constant, has a maximum, this point being referred to as the "optimum" intensity. (*See* fig. 12.) The shape of the curve as well as its absolute values seems to vary with the type of the emulsion and also with the wave-length of the light that is used. The work of L. A. Jones and V. C. Hall has shown the great importance of the reciprocity law in sensitometric work. It would therefore appear desirable that exposures in sensitometric instruments should not only be continuous but of the intensity level likely to be used in practice.

The original photometer with two light sources used by Hurter and Driffield has been superseded by polarization instruments for measuring the densities, and these in turn appear likely to be superseded by physical photometers, such as those employing

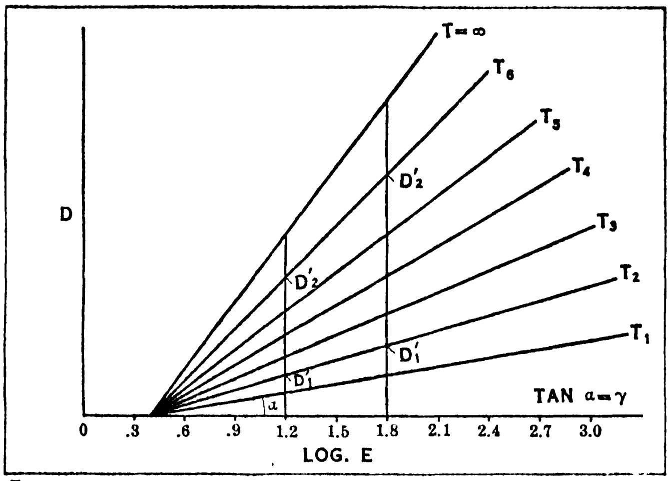

FIG. 13 —CHANGE OF DENSITY AND GAMMA WITH TIME OF DEVELOPMENT

photo-electric cells. The density obtained depends on whether it is read in contact with a diffusing screen, such as opal glass, or whether it is observed by parallel light from a collimator. With the latter, as was pointed out by Abney, Chapman Jones, and A. Callier, much of the incident light is scattered, so that the density has a higher value than when measured by completely diffused light. The ratio between $\frac{\text{density of parallel light}}{\text{density of diffused light}}$ was termed Q by Callier; it varied in amount from approximately unity to values as high as 1·6. The value of Q for average negatives is about 1·4.

Recently graduated wedges of neutral tint have been used very largely in sensitometry both for exposing and for the measurement of densities.

A point of considerable importance in speed determination is that of the fog inherent in the emulsion and developed without light action. Hurter and Driffield assumed that this was constant throughout all densities, or, in other words, through all exposure periods; but such is not the case, there being actually more fog in the underexposure period than in the more exposed parts, because there is less silver bromide available and also more bromide set free here than in the less exposed parts.

Returning to fig. 11, it will be observed that the tangent of the angle at which the straight line meets the exposure axis is marked a. This angle is of great importance in photography, since it defines the contrast of the image. The tangent of the angle, that is, the slope of the straight line, was termed γ by Hurter and Driffield and was called the "development" factor, since its value depends upon the time of development. During development, the value of γ increases, the increase tending to reach a limiting term, gamma infinity ($\gamma\infty$), which measures the extreme contrast of which a plate is capable. Thus, if we develop for different times plates which have been given a series of exposures increasing in geometrical proportion, measure the densities, and plot the resulting curves, we shall get the result shown in fig. 13, in which are shown curves corresponding to development times of 1 min., 2 min., 4 min, 5 min., and 6 min., while $T\infty$ corresponds to the maximum development that can be given before the contrast diminishes owing to fog.

If now we plot γ or density as a function of time, we get a curve of the type shown in fig. 14. It will be seen that the value of γ increases rapidly at first and then more slowly, finally reaching a limit $\gamma\infty$. This is an exponential curve, the rate of development

being proportional to the amount of exposed halide remaining to be developed, so that the reaction is identical in form with that of a chemical reaction of the first order. The velocity of the reaction of development depends therefore upon the value of $\gamma\infty$ which is a property chiefly of the sensitive material although also, to a minor extent, of the developing solution, and of K, the velocity constant of development, which is dependent upon the composition and temperature of the developer.

When bromide is present in a developer, the straight-line portions of the characteristic curve when produced do not meet upon

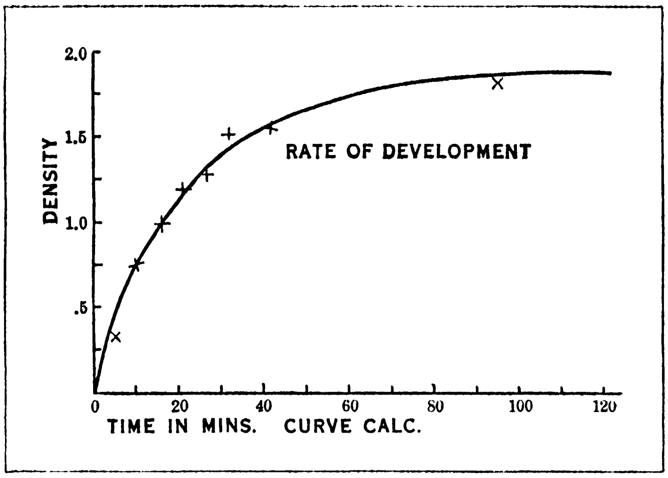

FIG. 14.—γT CURVE, SHOWING GROWTH OF γ WITH INCREASING TIME OF DEVELOPMENT

the exposure axis but at a point somewhat below it, the effect of bromide being equivalent to a constant depression of density in the straight line portion of the curve. (*See* fig. 15.)

The photographic characteristics of printing papers can be measured by a procedure similar to that used for negative materials, but in this case it is not the mass of reduced silver which is of chief importance but its relative reflecting power. The reflection density is thus the logarithm of the reciprocal of the reflecting power ($D = \log_{10} 1/R$), the reflecting power being measured with illumination at 45° to the plane of the paper. The characteristic curves obtained with different times of development are shown in fig. 16, and it will be seen that the effect of increase in time of development is to produce a regression of the inertia without change in γ except in the very earliest stages, where the curves are usually of a distorted form. The following constants may be derived:—

Constant	Symbol	Significance
(*a*) Maximum (reflection density) .	Dmax	Highest attainable density.
(*b*) Contrast element (reflection density) . .	$\frac{dD}{d\log I}$	Differential.
(*c*) Gamma element (reflection density) .	γr	Value of (*b*) for straight-line portion, or at inflexion-point.
(*d*) Latitude element (reflection density) . .	L	Range of intensities reproduced on straight-line portion.
(*e*) Rendering power (reflection density) . .	R	$\frac{10L}{S}$
(*f*) Total scale (reflection density) . .	S	Range of intensities reproducible by density differences.
(*g*) Standard exposure (reflection density) . .	Es	The exposure in m.c.s. necessary to print through a negative density of 2·o.

Tone Reproduction.—When a photograph of a natural object is made, the form can be represented only by differences in brightness. The accuracy with which the form is represented depends upon the precision with which the tones of the original subject are reproduced, and this question, generally known as the *theory of tone reproduction,* is fundamental to every photographic application.

Psychologically, it is the apparent brightness which is of importance, but this can conveniently be treated as the physical brightness modified and interpreted by the eye and brain, and since it can be shown that the apparent brightness is proportional

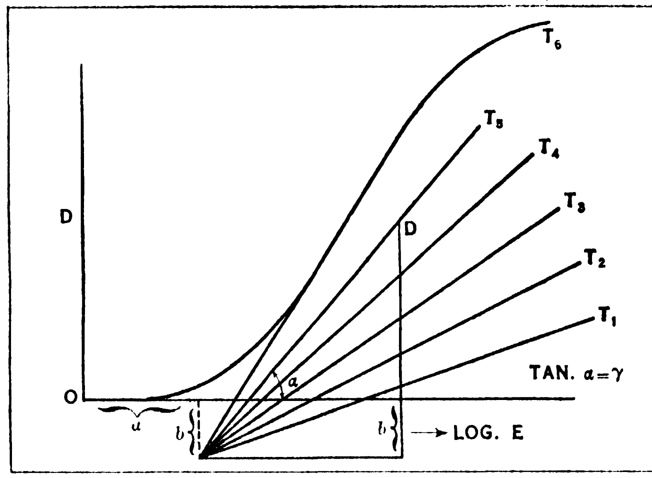

FIG. 15.—BROMIDE DEPRESSION CURVE. BROMIDE IN THE DEVELOPER CAUSES A DEPRESSION OF THE CONVERGENCE POINT

to the physical brightness throughout a wide range, it is generally sufficient for tone reproduction in photography to deal with the physical tones in the original and the reproduction.

The differences in brightness which occur in nature may be produced by differences either in the reflecting power of the different portions of the subject or by differences in the illumination. Since in natural scenes both the reflecting power and the illumination vary, some parts of a landscape consisting of clouds in sunlight and others of dark rocks in the shade, the range of contrast is often very considerable. For photographic purposes a scale or contrast of 1 to 4, in which the brightest thing is only four times as bright as the darkest, is low, and such a subject would be called flat; a contrast of 1 to 10 is a medium soft contrast; 1 to

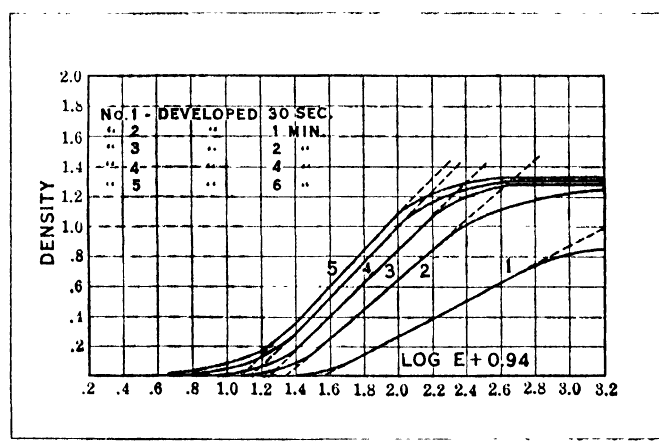

FIG. 16.—CHARACTERISTIC CURVE OF PAPERS WITH INCREASING TIMES OF DEVELOPMENT. INCREASING TIME OF DEVELOPMENT PRODUCES REGRESSION OF INERTIA WITHOUT AFFECTING γ EXCEPT DURING INDUCTION PERIOD

20, a strong contrast; 1 to 40, very strong; and 1 to 100, an extreme degree of contrast. All these degrees of contrast occur in subjects such as landscapes, street, and seashore scenes.

When a photograph is made, the operation is done in two separate steps. A negative is first made, in which all the tones of the original are inverted, the brightest part of the subject being represented by the deposit of silver in the negative which lets through the least amount of light, and the darker parts represented by the transparent areas; this negative is then printed upon a sensitive paper to form a print in which the scale of tones is again reversed.

In order to study the relation of the tones of the print to those of the original subject, the changes of those tones must be followed through both steps. In the making of the negative, the reproduction of tone will depend upon the characteristic curve of the photographic material shown in fig. 11.

If the exposure is so arranged that all the tones of the original subject fall on the straight-line portion of this curve, the inverse reproduction in the negative will be proportional, and if, in addition to this, development is so arranged that the negative has a γ, that is, slope of the straight line, of unity, then the reproduction will be correct. In the print it is necessary that γ should also be unity or, if the γ of the printing material is not unity, it is necessary that the γ of the negative should be modified suitably, so that γ_{neg} multiplied by $\gamma_{pos}=1$.

As is seen by reference to fig. 16, the straight-line portion of a paper curve is usually short, and it is necessary, moreover, in printing to utilize at least the underexposed portion of the paper curve. In making a paper print, therefore, the tone values are always distorted to some extent, especially those in the highlights corresponding to the underexposed portion of the paper curve, only the portion of the picture falling on the straight-line portion of the characteristic curve of the paper being correctly rendered.

The computation of the tone reproduction given in any photographic operation is of great importance, especially in the applications of photography, such as processes of colour photography or of the reproduction of sound; and for the methods which are used, the papers by F. F. Renwick and L. A. Jones should be consulted.

Resolving Power.—The resolving power of photographic materials may be defined as the closeness of two adjacent images which can be just distinguished. It is limited primarily by what is termed the irradiation or spreading of the image due to diffusion of the light in the film. This spreading of the image has been investigated by astronomers and used as a basis for a method of stellar photometry. (*See* PHOTOMETRY, CELESTIAL and PHOTOGRAPHY, CELESTIAL.)

In addition to the irradiation factor, the resolving power depends upon the development factor attainable in the material. The sharpness of an image, in fact, is theoretically equal to the development factor divided by the turbidity factor. Both of these factors are functions of the wavelength of the light used in exposure, so that the resolving power is naturally dependent upon the colour of the light. In addition to these two factors, a psychological factor enters into the resolution of the image.

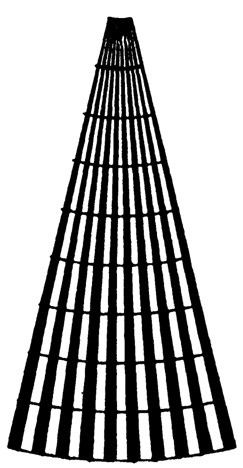

FIG. 17.—FAN TEST OBJECT, USED FOR MEASURING THE RESOLVING POWER OF PHOTOGRAPHIC MATERIALS

The practical resolving power of photographic materials can be measured by photographing (*see* fig. 17) and measuring the extent to which the lines are resolved.

Photographic images on development show with low power magnification, as used in projection and enlarging, a granulation which is objectionable in such operations. L. A. Jones and N. Deisch have shown that it may be measured and numerically expressed on the assumption that the graininess is directly proportional to the distance at which it becomes just visually imperceptible, this being compared with the distance at which a structure of known period, *e.g.*, a fine cross-line screen, just disappears. Suppose a screen of 2,000 lines to the inch to be equivalent in this way to a given granularity of the developed image; the latter may be said to have a graininess of 2,000.

The Photography of Coloured Objects.—Since photography makes a black and white reproduction of the tones of natural objects, all of which are to some extent coloured, the way in which different colours are reproduced in photography is of considerable importance. The earlier photographic materials were sensitive only to violet and ultra-violet light, and if an object containing blues, greens, and reds was photographed, the greens and reds were rendered dark while the blues were rendered much lighter than they appeared to the eye.

Following Vogel's discovery of the sensitizing power of dyes, this inaccuracy in rendering was to some extent mitigated by the introduction of so-called "orthochromatic" materials which, however, were sensitive only to the yellow-green in addition to their normal blue-violet and ultra-violet sensitiveness and were therefore unable to render the full scale of colours as seen by the eye.

After the production of the isocyanine and carbocyanine sensitizers, *panchromatic* plates were introduced, sensitive to the whole visible spectrum. These plates still retain the high sensitiveness to blue, violet, and ultra-violet characteristic of photographic materials generally, but by the use of light filters (*q.v.*) with them, it is possible to obtain an *orthochromatic* rendering; that is, one in which the reproduction of the different colours follows very closely their relative brightness as they appear to the eye. This is accomplished by the use of a yellow filter which absorbs all of the ultra-violet and most of the blue-violet, reducing the effective sensitivity of the material approximately to that of the eye.

By the use of yellow filters, therefore, and panchromatic plates and films, approximately correct colour rendering is now used very largely in practical photography. Sometimes, however, subjects have to be photographed which are visible to the eye by virtue of their colour contrast. Suppose we have two objects, one contiguous to the other and separated purely by their colour contrast, such as, for instance, a yellow straw stack against a deep blue sky. In this case, orthochromatic rendering would produce a photograph in which both would have the same intensity, and they would be indistinguishable. It is necessary in this case to use a colour filter which will introduce a certain amount of incorrect rendering in order to reproduce the colour contrast. This filter may, for instance, be a red filter, in which case the straw stack will appear brighter than the sky or, it may be a blue filter, in which the sky will appear brighter than the stack. The choice of such filters is an important task for the skilled photographer. Contrast filters are used very largely in photography for special purposes. They are of great value in photomicrography and are used in commercial photography to a large extent. The deepest possible filter is also used in aerial photography in order to take advantage of the power of the longer wave-lengths to penetrate haze. (C. E. K. M.)

PHOTOGRAPHIC MANUFACTURE

The manufacture of photographic sensitive materials is a very specialised industry. Approximately 40,000 people are employed in the whole photographic industry throughout the world, about 20,000 being engaged in the manufacture of materials sensitive to light, with which this section deals, and the remainder in the manufacture of cameras and in the wholesale distribution of the products to the retailer.

With the introduction of the gelatine dry plate, the preparation of materials by photographers for themselves diminished very rapidly, and the manufacture of ready-prepared material took its place. The first dry plates appear to have been placed upon the English market in 1877. In 1880 the manufacture of gelatine dry plates was general in England and was commencing in Belgium, Germany, France, and the United States.

Until 1900 the photographic industry was usually carried on in small factories under the direct personal control of the founder. At the present time, however, photographic manufacture is organised chiefly in modern factories manufacturing on a large scale, and using specially designed machinery at every step of the process. In the largest of these factories, the output of motion-picture film alone exceeds 150,000 miles yearly. Over 5,000,000 lb. of cotton are used each year for the manufacture of film, and over three tons of pure silver bullion are used each week. The total power required exceeds 20,000 h.p., and the consumption of coal is over 500 tons a day.

The process of manufacture may be divided into three distinct

sections: (1) The preparation of the base; (2) the preparation of the emulsion; (3) the coating of the emulsion on the base and the cutting and packing of the material so prepared.

Preparation of the Base. *Glass Plates.*—Photographic glass is the specially selected, best quality of thin sheet glass made in a factory which prepares sheet glass for all purposes. Even under the best conditions only about a quarter of the sheets made are fit for photographic use, the remainder being used for glazing. Photographic glass is made very largely in Belgium in the factories near Charleroi, and in England at St Helens. A considerable amount is also made in the United States. The glass is supplied cut to sizes which are multiples of those used by photographers. The glass arrives packed in straw in boxes holding usually about two gross sheets, and after unpacking and preliminary inspection, is cleaned by an automatic machine into which it is fed. The glass plate is received between rollers and passes through a strong solution of soda between revolving brushes which remove the dirt from the surface, and at the end of the machine is coated with a substratum, usually a weak solution of gelatine containing chrome alum, by means of which the emulsion is made to adhere to the glass. The glass is then dried in a heated oven, examined for defects, and if passed is packed in a tray and transferred to the coating room

Film Base.—In the manufacture of film base the first step is the preparation of cotton linters for nitrating, the treatment consisting of cleansing the linters very thoroughly and drying them. They are then nitrated in centrifugal machines, and when they have absorbed the necessary amount of nitrogen, 12 to 13%, the resulting nitro-cotton is soused in water and the washing commenced. This washing is a long process, and is continued until the material is entirely free from absorbed acid, after which it is dehydrated, the water being then displaced by alcohol The dehydrated nitro-cotton is then dissolved in tumbling barrels or mixers in suitable solvents, those commonly employed being acetone and methyl alcohol, and at the same time the so-called softeners, such as camphor, are added, these resulting in a flexible film The viscous nitro-cotton solution, which appears rather like honey, is known in the United States as dope. This is now spread out into a thin film by coating it on a travelling surface. In the United States the coating is generally done on large wheels about four feet across and about fifteen feet in diameter which rotate slowly about their axes so that by the time one rotation is completed the solvents have been evaporated sufficiently to set the film, which can be stripped off the wheel, and dried further by passing over drums. The operation is thus continuous, the film base, as it is called, being prepared in rolls of about 2,000 feet In Europe it is customary to coat a film about 24 inches wide upon a metallic belt from which after one rotation the film can be stripped in the same way as from a drum The surfaces of these belts and drums must necessarily be prepared very carefully, the wheels being usually made with a highly polished nickel surface, while the makers of the belt machines recommend that they be coated with gelatine. The film has a high polish on both surfaces and may be used at once or stored or seasoned until required. Before coating with emulsion, one side is treated with a substratum, which is really an etching solution that slightly roughens it, and gives a tooth that holds the emulsion firmly. For camera film, the back is coated with a non-curling coat of hardened gelatine, which, imposing an expansion strain on this side, equalizes that of the emulsion on the other. Camera or roll film base is about 3½ thousandths of an inch thick; motion picture film, about 5½ thousandths; and cut film, such as portrait and X-ray, which are used flat, about 7½ thousandths. Still thicker cut films are sometimes used, about 10 thousandths, but the celluloid for these is cast into blocks and then sliced, the knife marks being removed by heat polishing.

Since cellulose nitrate is highly inflammable, itself supplying the greater part of the oxygen which it requires for combustion, much work has been done on the preparation of film which is not inflammable. The most promising substance for this purpose is cellulose acetate, prepared by treating hydrated cellulose with acetic acid and acetic anhydride in the presence of a suitable catalyst. Acetate film burns with about as much difficulty as thick paper, and should it catch fire it is very easy to extinguish. This acetate base is used under all conditions where proper precautions against fire cannot be taken, as where films are used in homes or schools. Sixteen millimetre film for amateur cinematography is made only on acetate base.

Photographic paper base is generally made by mills which specialise in its manufacture, but in the United States the bulk of the photographic paper base is made in the factory where the rest of the production of photographic paper is carried on. The paper is prepared very largely from rag stock, although refined cellulose from wood is sometimes added. After inspection the raw rag stock is washed and digested and is then treated in the beater until it will make a homogeneous, strong sheet Great care is necessary to exclude traces of impurities and especially of metals such as copper and iron from the paper stock The composition differs with the purpose for which the paper is used The finest kinds are prepared from linen rags, which are bleached with gaseous chlorine or hypochlorites, any excess being removed by treatment with sulphites or thiosulphates which are then washed out. Any residual trace of colour is neutralized by the careful addition of a complementary colour, such as indanthrene blue, or if a chamois or toned base is desired the bleaching may be omitted or indanthrene yellow added A resinous soap is usually incorporated with the fibres and precipitated with alum, and the paper may be later subjected to a sizing with gelatine Throughout all its treatment great care must be exercised to avoid the occurrence of metallic particles, which would act prejudicially on the sensitive emulsion. The paper is generally cast about 41 in. in width and from 500 to 1,000 yd in length It is calendered either to give it a closer texture or higher surface or to impart some special linen or fabric-simulating finish.

The paper is usually given a coating of baryta before it receives the photographic emulsion. In this process a suspension of baryta (barium sulphate) in gelatine is coated over the surface of the paper, several coatings being sometimes applied, and not infrequently the paper is calendered after baryta coating in order to get a perfectly smooth glossy surface Baryta-coated paper is transferred to the emulsion coating-room in rolls of about 2,000 feet.

Emulsions.—Emulsions are of two general types: washed and unwashed Emulsions to be coated on glass or film are always washed In the first case the precipitation of the silver salts is effected by adding a solution (about 10% in strength) of silver nitrate to a small quantity of gelatine dissolved in a solution of the halide salts which, in the case of negative emulsions, are usually potassium bromide containing a small proportion of potassium iodide. When precipitation is complete, the emulsion is digested in order to produce an increase of sensitiveness, and the bulk of the gelatine is added so that when cooled it will set to a jelly. Instead of increasing the sensitiveness of the emulsion by holding it at a high temperature for some time, it may be digested at a lower temperature in the presence of ammonia, and not infrequently the silver nitrate is precipitated with ammonia and then re-dissolved in excess before the precipitation of the halide is commenced. The set emulsion is cut up into small portions and is washed in running water in order to remove any excess of halide salts and also the soluble nitrate produced in the reaction. After washing it is given a final digestion and is ready for coating upon the base.

The emulsions used for printing papers are of three general types. bromide papers, which are made with a washed emulsion essentially identical with that used for coating upon glass and film for use in making lantern slides and positive motion pictures; unwashed chloride emulsions in which the emulsion is coated on the paper in the form in which it is mixed without any removal of the soluble salts by washing; and emulsions also made without washing but in which the silver salts are a mixture of chloride and citrate, and in which there is free silver nitrate present. These papers darken visibly when exposed to light and thus give a printed-out image which is then toned and fixed.

Coating and Packing.—Dry plates are coated by passing the

prepared glass sheets on a travelling belt under some device through which the emulsion is allowed to spread out over the surface of the glass. This may take the form, for instance, of a trough with a slit in the bottom or of a stepped weir down which the emulsion flows, reaching the plate by means of a flap which rests lightly on the surface of the plate. The coated glass travels forward on to a belt or rollers which are kept wet with ice-cold water, and there the emulsion sets. At the other end of the machine the plates are taken off, placed on the racks, and dried slowly and evenly. They are then cut to the requisite sizes by means of machines using diamonds and are packed in boxes of one dozen for supply to the market.

The most usual size of plates are $2\frac{1}{2}''\times3\frac{1}{2}''$, $4''\times5''$, $5''\times7''$, $8''\times10''$, $11''\times14''$, and $14''\times17''$, in the United States; $4\frac{1}{4}''\times3\frac{1}{4}''$ ("quarter plate"), $6\frac{1}{2}''\times4\frac{3}{4}''$ ("half plate"), $8\frac{1}{2}''\times6\frac{1}{2}''$ ("whole plate"), $12''\times10''$, and $15''\times12''$, in Great Britain (where the larger dimension is given first for inch sizes, the contrary practice being used in the United States); and 6×9 cm, 9×12 cm., 10×15 cm, 13×18 cm., 18×24 cm, 24×30 cm, and 30×40 cm., in countries using the metric system

For coating both film and paper the same type of machine may be used (*See* Plate V., fig. 2) The stock roll of the base is carried on a mandrel, freely revolving, and is led over and under rollers that keep it taut, to the coating trough into which the fluid emulsion is fed continuously and automatically at the rate at which the base takes it up The base passes under a roller, dipping into the emulsion, and it hugs this so tightly that no emulsion finds its way on to the back. The temperature and viscosity of the emulsion are kept constant, and the thickness of the coat is determined by the rate of travel of the base through the emulsion—the faster the travel, the thicker the coat, and vice versa The coated base then passes up a vertical run-up, which allows the film of emulsion to even itself out, or it passes over a chill roll and then through a refrigerating chamber, where cold air is blown on to the emulsion surface and thoroughly sets it. Leaving this chamber, the film is automatically looped into festoons varying from five to twenty feet in length and travels slowly through the drying tunnels. To these is supplied heated air which has been thoroughly washed with water sprays to remove all dust and deleterious gases The humidity and temperature of the air used for drying is adjusted very carefully and it is usually recirculated through the system, being driven in at one end of the drying room and exhausted at the other, and then reconditioned before entering the drying chamber again. Frequently the festooning apparatus makes a right-angled turn so that the prepared material is reeled up side by side with the coating machine; the operations of coating, drying, and reeling are continuous and automatic

Motion picture film is slit from the original roll to the exact width required, 35 mm ($1\frac{3}{8}$ in.) in the case of standard film, and before packing is perforated on the edges in accordance with the standard gauge used for the cameras and projection machines. The maker's name and private mark are light impressed on the margins, becoming visible only on subsequent development, while on negative film every foot is numbered in order to aid in the identification of the scenes. Negative film is supplied not only coated with ordinary emulsion, but also panchromatized, which gives far better rendering of all colours and permits considerable shortening of exposures, especially under the artificial illuminants, such as the mazda and other lighting systems now so much in vogue in the studios. The speed of the emulsion is very high and a special hypersensitised film is obtainable, which places in the hands of an operator the possibility of photographing poorly lighted subjects. Positive film is supplied either on nitrate base, that used most generally, or on acetate safety base, which is slow-burning. For amateur motion picture photography film is supplied 16 mm. in width on slow-burning acetate base only and is supplied in lengths of 100 ft packed with paper leaders at the ends and on a special protective spool so that the cameras can be loaded in daylight. This film is made to be reversed directly to a positive so that the same film that is used in the camera is employed for projection.

to the desired lengths, and spooled on wooden cores with light-excluding metal flanges. A light-protecting apron of black paper is wound with the film, so that the cartridge may be inserted in the camera in daylight; or red paper with an inset of carbon paper is used instead of the black, so that records may be made on the film after exposure. Film is also cut into sheets, to each sheet being attached a numbered tab, and the sheets are assembled into a film-pack, which is usable in any ordinary plate camera After each exposure, the tab is pulled, which draws the exposed film to the back of the pack, and the tab is torn off and thrown away.

For X-ray work, the film is coated on both sides with emulsion; this gives greater contrast and better rendering of shadow detail, for the rays can penetrate both emulsion layers with but little loss of action. The film is used in holders like those for plates, except for dental work Films for this purpose are packed in special flexible, light-tight holders ready for use

Paper is cut from the roll into sheets, and the sheets stacked on the top of each other are cut by means of guillotines to the size required for the market, each sheet being inspected for defects before packing. (G Ea.)

COLOUR PHOTOGRAPHY

In 1810 J T Seebeck obtained a coloured effect by exposing to the spectrum silver chloride which had been darkened by exposure to light This experiment has often been repeated, but as the colours obtained cannot be fixed, it has no practical value

In 1891 G. Lippmann of Paris produced the first picture by interference heliochromy, although the possibility of doing so had been pointed out by W. Zenker in 1868, Lord Rayleigh in 1887 and O Wiener in 1890 In this method a perfectly transparent grainless emulsion is coated on plate glass and exposed through the back with the sensitive surface in contact with a reflecting surface, such as mercury. The incident light is reflected back on itself, giving rise to interference, thus setting up stationary or standing waves in the emulsion with their crests or loops exactly half a wave-length apart. These standing waves produce exposure effects so that on development, the silver is deposited in laminae half a wave-length apart and reflects light of double the separation, giving bright colours Unfortunately the plates are very insensitive, and as the results can be viewed only in the hand or by projection with a special outfit, the method is not in general use

Tricolour Photography.—The methods which are used at the present time for reproducing objects in colours by photography are dependent upon the suggestion made by Clerk Maxwell in 1861 Any colour may be reproduced by a mixture of the three primary colours, red, green, and violet. In order to reproduce any colour, therefore, we may analyze the different proportions of these three primary colours in it and then synthesize the colour by superimposing the three primaries upon a screen in projection To illustrate this, Maxwell took three photographs of a coloured ribbon. one through a red solution, one through a green solution, and a third through a blue solution From these three negatives, three transparencies were made, each of which was projected by means of the coloured light by which it was taken, Maxwell adding a fourth picture taken and projected by yellow light

In 1869 Ducos du Hauron published a small book on colour photography, in which he laid down the principles of three-colour photography, on which all later work has been based, and at approximately the same time Charles Cros published an article in which he had independently come to much the same results. Du Hauron's book is astonishingly complete and contains a very clear account of the two fundamental processes of colour photography including their application by different methods. These processes are known as the "additive" (that employed by Maxwell) and the "subtractive" processes

The practical development of colour photography was, however, delayed for many years by the difficulty that the photographic materials available were sensitive only to the blue and violet of the spectrum; it was with the greatest difficulty that materials sensitive to the whole visible spectrum could be ob

The introduction of colour sensitizing by Vogel in 1873 first made colour photography possible, and the introduction of the isocyanine and carbocyanine sensitizers at the beginning of the 20th century made it practical.

The Additive Process.—Clerk Maxwell's picture was projected on to a screen by means of optical lanterns and was thus the so-called "additive" process; that is to say, the colours were formed by adding light to light. This method was also used by du Hauron and Cros in a special instrument called a chromoscope, in which the three pictures were viewed in superposition; a plan later used and developed by F. E. Ives also.

F. E. Ives developed the additive process in practice. He took photographs through three dyed gelatine filters upon materials sensitised with the best dyes available at that time and projected the transparencies by means of triple lanterns devised for the purpose, these synthetic colour pictures giving extremely good colour reproduction upon the screen.

The production of the negatives can be accomplished by three different methods. For stationary objects where an interval between the exposures is of small importance, it is convenient to fit the filters and sensitive plates into a sliding back attached to an ordinary camera. Exposures are then made through the three filters in succession either upon a single panchromatic plate or on three separate plates.

For the photography of moving objects, it is, of course, impossible to use successive exposures, and a great number of cameras embodying beam splitting methods either by means of prisms or by reflectors have been designed. The chromoscope already referred to as a "viewing" instrument can be converted into a camera in which mirrors are used for separating the three beams. Other cameras use elaborate combinations of prisms for the same purpose. In such cameras it is often convenient to use separate plates, since it is rather difficult to arrange for the three images to fall upon a single surface.

A system invented originally by du Hauron is to have the sensitive surfaces superposed on each other and to build up a plate or film pack; thus, in front, there may be placed a slow, very transparent yellow-dyed, blue-sensitive film; behind this, a moderately transparent film sensitive to green and dyed red or with a red filter attached to it; behind this again, a red-sensitive film. In this way, the blue record is made on the first film, the green record on the second, and the red on the third. A considerable number of patents have been taken out for variants of this method.

The Subtractive Process.—The subtractive process, which was described originally by du Hauron, depends upon the production of colours by subtractive absorption instead of by the addition of the colours to each other in projection. Suppose that over a sheet of yellow gelatine, which will absorb the blue light, is put a sheet of magenta gelatine, which will absorb the green light; then, since the yellow absorbs the blue light, and the magenta the green light, only the red light is transmitted; a red image can thus be obtained either by projecting it through a red filter or by putting a magenta image on the top of a yellow one. In the same way a green image can be obtained by putting a blue-green one on the top of a yellow one, when the yellow will cut the blue out of the blue-green and leave only green.

In working the subtractive process, the three negatives are printed in coloured dyes, the picture taken through the red filter being printed on gelatine dyed blue-green, the one taken through the green filter on gelatine dyed magenta, and the one taken through the blue filter on gelatine that was dyed yellow. Now, if the three are cemented together in register, the resulting transparent colour picture will reproduce the colours of the original subject and will be a transparency which can be viewed in the hand, or examined in front of an artificial light, or projected in a lantern.

Printing Methods.—Subtractive methods have naturally attracted the most attention as alone giving prints on paper.

The carbon process was used by du Hauron, the negatives being printed upon carbon tissue containing a pigment of colour complementary to that of the filter. After development, the three images are transferred to a temporary support, and then retransferred to a permanent support in accurate register. This method gives excellent results but requires considerable skill.

Very good results have also been obtained by the use of a process in which gelatine containing transparent dye was coated on thin film base. After sensitising with bichromate, this can be printed through the back and developed with hot water, so that a coloured relief image is obtained on the film. The three images can then be transferred in superposition on to a paper support without the use of double transfer.

A modification of the carbon process, suggested by T. Manly under the name of "Ozobrome" and later revived by H. F. Farmer as the "Carbro" process, is also used for colour work. In this a silver image is squeegeed into contact with pigmented gelatine saturated with bleaching solutions whose reduction products harden gelatine. These chemicals migrate into the silver image film, and the reduction products return to the tissue, rendering it insoluble in ratio to the amount of metallic silver present in the image. The tissue is then treated exactly as in the carbon process. Bromoil transfers are also used by some artistic workers.

In addition to these processes, colour images have been made by using for dyes the mordanting power of chemical compounds and especially the ferrocyanides of the metals. The ferrocyanides of uranium, copper, vanadium, and silver, and the iodide or sulphocyanide of silver mordant basic dyes very strongly. From the negatives silver images are therefore prepared and transformed into these compounds. The blue image is commonly composed of iron ferrocyanide itself, this being a very suitable shade of blue for colour work. Yellow and red images are obtained by mordanting basic dyes, such as auramine and safranine, on to transparent deposits of metallic compounds. The three images are then superposed as usual.

In one group of processes the dye images themselves are transferred from the printing plates, which are formed of colourless reliefs, these being stained up and then placed in contact with gelatine so that the dye migrates and forms an image in the gelatine. Such processes are known as "imbibition" processes. The transfer plates may be made in several ways: thus, bichromated gelatine on film may be exposed through the back and developed with hot water, or a silver image produced by exposure through the back of an ordinary emulsion coated film may be caused to harden the gelatine either during development, since some developers harden the gelatine contiguous to the image, or by treatment with a bath similar to that used in the ozobrome process already referred to. After treatment, a relief can be obtained by washing off the unhardened gelatine with hot water, and after removal of the silver a colourless relief is obtained. In a process known as the "Pinatype" process, bichromated gelatine is exposed under a positive and is then treated with dye which penetrates only the soft gelatine, the hard gelatine remaining uncoloured. This dye can then be transferred by imbibition to a layer of soft gelatine coated on paper, and the three images can be transferred in turn to produce a colour picture.

In a modification of this, used in motion picture colour photography, the local hardening is produced not by the light exposure of a bichromated surface but by the formation of a silver image and its treatment with a bleach bath which hardens the gelatine in contact with the developed silver.

There are numerous modifications of these printing processes all of which can be employed with more or less success but all of which require a considerable amount of skill if really good results are to be obtained.

The largest field for the subtractive process of colour photography is in connection with the use of the printing press. The three negatives are used for the production of printing plates, usually by the half-tone process, and prints from the three plates, frequently with a fourth black plate added, are superimposed, the plates being printed in red, blue, and yellow inks which are approximately complementary to the colour of the taking filters. This three or four colour half-tone process is very widely used for the preparation of illustrations and is by far the greatest application of colour photography. (*See* PHOTO-ENGRAVING.)

Screen Plate Processes.—In his book, Ducos du Hauron suggested a modification of the additive process which has since become of practical importance and is known as the "screen plate" process. He suggested that the surface of the glass plate or film might be covered with tiny filters—red, green, and blue—the sensitive emulsion being coated on top of these and photographed through the filters.

A modification of this method was suggested by J. Joly of Dublin and by J. W. MacDonough of Chicago in 1892; the colour elements were on a glass plate which was pressed during exposure into close contact with a separate panchromatic plate after development of the negative; a positive in silver was made in the usual way and viewed in contact with a special viewing screen, in which the colours approximate those required by theory. The advantage of this method is that should any error be made in exposure of manipulation, the negative plate alone is lost, the taking screen being still available for further work, whereas with the combined methods the screen-plate is ruined. The disadvantage is that it is applicable only to regular, geometrical patterned elements, the fineness of which is therefore limited to some extent.

In 1907 Messrs Lumière and Co., of Lyons, brought out their "Autochrome" plates in which they utilized an irregular screen composed of coloured grains. Glass plates are coated with an adhesive medium over which there is spread a mixture of starch grains, of microscopic fineness, stained violet, green, and orange, the interstices being filled in with fine carbon powder to form a tri-colour screen, dark by reflected, and of a pinkish, pearly appearance by transmitted, light. This is varnished and coated with a thin panchromatic emulsion of gelatino-silver bromide The plates are exposed in the camera from the back, through the tricolour films, a special compensating orange-yellow screen being used also before or behind the lens. They are then developed as usual, producing a negative coloured image in the complementary colours, which is then reversed so as to produce a positive coloured image showing the picture in its proper colours. The results thus obtained are remarkably good and practically solve the problem of direct colour photography in a simple and fairly inexpensive manner, the results being of course confined to transparencies.

Other screen plates which have been introduced include the Agfa plate, invented by Christensen, in which the elements are slightly larger than those of the Autochrome, and the Lignose colour film with still larger elements. In both these the colour units are stained resins, which like the starch grains are applied either by a dusting-on or sedimentation process.

The Duplex, originally known as the Paget, belongs to the separate system, and taking and viewing screens are used, the former with a panchromatic plate. This screen is produced by printing the units on bichromated gelatine in contiguous squares.

Screen plates are conveniently studied under the following heads:—

I. Method of production of the screen.
II. Examination of the screen as a whole.
III. Examination of the filter units.
IV. Examination of the emulsion.
V. Adjustment of the compensator and emulsion to the filters.

I. The screen may be either regular or irregular. The methods of production may be classified as follows:

(1). Ruled lines. Method used by Joly and MacDonough.

(2). Dusting-on methods. Employed to produce irregular screens in the Autochrome, Agfa, and Lignose processes.

(3). Printing by means of bichromated colloids. These are used in the Warner-Powrie and Duplex processes.

(4). Various methods of section cutting. The best known example is the Krayn screen introduced in Germany in 1907 and taken off the market shortly afterwards.

(5). The use of mechanical printing or a combination of mechanical printing and dyeing. Experimental screens made in this way were the Omnicolore and the Lumière regular screens, neither of which was marketed commercially.

(6). Other processes. A variety of patents have been taken out for experimental screens which must be classed under this heading.

II. The screen as a whole when examined should appear to be of a neutral shade. This is known as the "first black condition." The adjustment is obtained by alteration of the area of the units as far as possible rather than by adjustment of the depth of colour. The total visual absorption should be as low as possible.

III. The separate filter units should have the purest possible colours, preferably without overlap in the spectrum. The best possible compromise is for a red filter transmitting from λ590 upwards; a green filter from λ590–490; and a blue filter from λ 500 down to the violet. The size of the screen units is determined by their invisibility. In order to get bright colours, however, it is necessary that they should not be too small, since otherwise the emulsion will not have sufficient resolving power, and the images behind the units will overlap. For regular screens the units should not be larger than $\frac{1}{300}$ nor smaller than $\frac{1}{600}$ of an inch. For irregular screens it is necessary that the units should not be larger than one-third the dimension of regular screens, since the average unit will tend to be a clump of about 10 grains; that is, having approximately three times the diameter of the single unit

IV. The emulsion should be sensitive to the whole visible spectrum and of a resolving power depending on the size of the units. In the case of the small units of irregular grains, its resolving power must necessarily be high, so that the emulsion must be slow and fine grained. It must also be coated in very close contact with the screen, since otherwise the scattering of the light in the intervening space will affect the colour.

V. The emulsion should be so sensitized that the effects produced under the red and green filters are equal if possible. The compensating filter used on the lens can then be adjusted to the emulsion and to the filter units, so that the "second black condition" is fulfilled; that is, a scale of greys is rendered as grey after exposure, development, and reversal

The effective speed of a screen plate is governed by three factors: (1) The sensitiveness of the emulsion, (2) the multiplying factor of the screen; (3) the multiplying factor of the compensator. The effective speed of the screen plates on the market is very low—from 1 to 2 H and D

Owing to the very thin emulsion necessary to give sufficient resolving power, the latitude of the process is small, and in subjects with wide contrasts the shadows may be underexposed, while the highlights lose colour owing to overexposure and the consequent irradiation Except with very flat subjects, there is practically no latitude in the exposure given in the camera, the results depending entirely upon the accuracy with which the exposure is determined

A process which is in some respects analogous to the screen plate process is one invented by R. Berthon in which film is embossed on the back with minute lenses A tricolour diaphragm is then placed at the lens of the camera and the film is exposed through the back so that the lenses form images of the coloured filters on the emulsion

After exposure and processing by reversal, the film is projected with a multi-colour diaphragm attached to the lens of the projector, and the colours of the original object are thus reconstituted on the screen. This process is used entirely in motion picture work.

Bleach-out Processes.—Since many dyes are destroyed by the action of light, and since Grotthus and Draper showed that dyes are bleached by light of the colour which they absorb, it is clear that a printing process can be produced by mixing three colour dyes which are sensitive to light. Thus, if we make a mixture of auramine—which is bleached by blue light; erythrosine—which is bleached by green light; and methylene blue—which is bleached by red light; and coat this mixture in a layer of paper, we shall get a black surface Now, if this be printed under a coloured original, the dyes which absorb the colours will bleach, and a coloured reproduction will be obtained, the accuracy of which will depend upon the correct adjustment of the conditions. The most important of these conditions is the relative sensitiveness of the different dyes and the choice of dyes which have the correct ab-

sorption. Since dyes such as those mentioned have little sensitiveness to light, it is necessary to increase it by sensitisers, and a great deal of work has been done in this field in the development of suitable sensitisers, of which the best known are Anethol and compounds of a similar nature.

A commercial bleach-out paper was placed on the market under the name of "Utocolour" paper and was employed particularly for the printing of screen plate originals. The results obtained were not very satisfactory, however, and great difficulties have been experienced in achieving any improvement in the process. It is difficult to adjust the three dyes to equality of bleaching. It is very difficult to remove the sensitiser and the bleached dye, and it is particularly difficult to stabilize the unbleached dye so as to produce a permanent picture. These various difficulties have prevented the process from coming into any general use. (For colour photography as applied to motion picture work, *see* MOTION PICTURES.)

APPARATUS

Photographic apparatus may conveniently be discussed under the following heads:—(1) Cameras and Enlargers, (2) Stands, (3) Lenses, (4) Light Filters, (5) Instantaneous Shutters, (6) Exposure Meters, (7) Prepared sensitive plates, films and papers, (8) Developing and Printing gear, and (9) Studio and Dark-room appliances. In the case of (1) and (3) further subdivisions will be needed. Owing to the multiplicity of models it will be necessary to curtail greatly the space devoted in former editions to historical development in order to deal at all adequately with features of construction, in relation, more particularly, to modern types. Even here severe compression has rendered unavoidable the omission of many details of mechanical and optical interest. For closer study of these the reader is referred to the works particularized in the short bibliography appended to this Section.

Incidentally, the consideration of photographic apparatus is complicated at the time of writing by certain prospective developments. Camera construction, and to some extent the manufacture of lenses and other gear, has hitherto been influenced mainly by three factors, the introduction of dry plates, enabling development of the latent image to be postponed indefinitely, the substitution of gelatine film for glass, and the perfection of methods of enlargement. Two factors are being added—the improvement of existing processes of colour photography and the swift expansion of cinematography—the precise effect of which cannot as yet be estimated. Already the production of amateur cine-cameras is enormous and, although "still" photography can never be completely ousted by motion picture production, the design and supply of apparatus for the former may conceivably be as seriously affected by the latter as the popularity of the old "stand" camera was by the appearance of the revolutionary Kodak.

CAMERAS AND ENLARGERS

The original aim of the pioneers in Photography was to fix the image in the camera obscura (*q.v.*), and Wedgwood and other early workers chiefly employed that cumbrous apparatus in their experiments.

Historical.—Between 1816 and 1839 Nicéphore Niepce, Fox Talbot and Daguerre used smaller box cameras, and it is on record that the expanding bellows-body principle was applied to some of the first cameras made in France for the production of Daguerreotypes. In England this construction was not adopted until much later, the usual practice being to make the camera in the form of two open boxes, one sliding within the other in order to provide the adjustment necessary for focussing. The two parts were supported on a rigid baseboard, the adjustment being fixed by a screw. A portable stereoscopic camera with parallel bellows

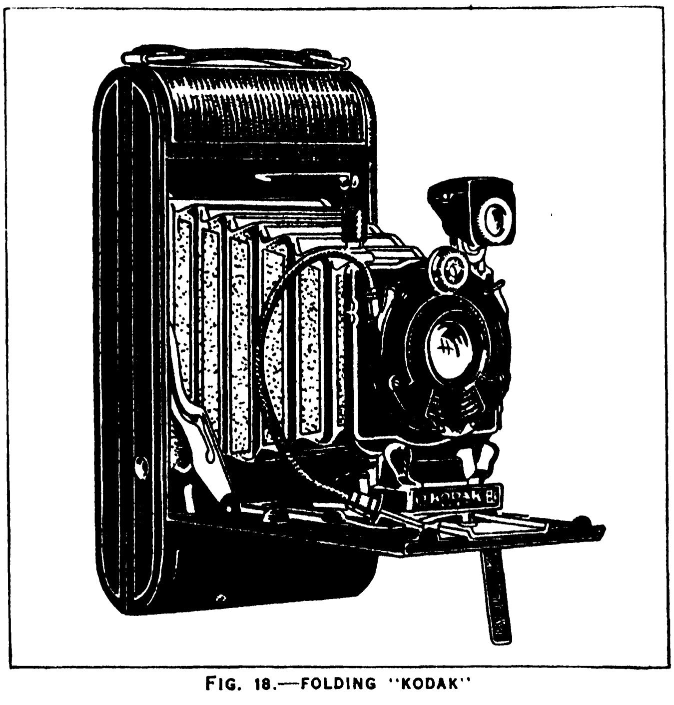

FIG. 18.—FOLDING "KODAK"

designed by J. Atkinson in 1857 was followed in 1858 by C. T. H. Kinnear's lighter pattern with conical bellows for general work. Thenceforward the manufacture of British cameras progressed rapidly in the hands of P. Meagher, G. Hare, W. Watson and other competent makers, one of the later models of the last-named, known as the "Premier," having survived to the present day as a typical "square-form" pattern for technical work.

Information on early cameras will be found in the photographic journals, in C. Fabre's *Traité encyclopédique de photographie*, Vol. 1, and in J. M. Eder's *Ausführliches Handbuch der Photo-*

graphie, 2nd ed., Vol. I, pt. ii.

With the advent of dry plates the demand for more portable cameras increased and has continued steadily to the present day when, the limit of compactness having probably been reached, attention is being concentrated on the provision of various movements, and of accessories such as shutters and finders, with no loss of rigidity and no increase of weight or bulk. Up to 1888, when the roll-film camera known as the "Kodak" was introduced by the Eastman Co. of Rochester, U.S.A., the early portable cameras were for the most part on the lines of the present "hand-or-stand" type.

Roll-film quickly produced a succession of Kodaks, box-form and collapsible, the latter culminating in a folding design which has been widely imitated in this country and on the Continent. To-day the output of roll-film cameras greatly exceeds that of any other type, but several other forms continue in request. Cut films, either put together in film-packs (*q.v.*) or exposed in sheaths, have increased the popularity of the extremely portable "hand-or-stand" cameras, such as the "Sybils" of Newman and Guardia and the more substantial "Una" of James Sinclair and Co. Stereoscopic cameras of exquisite workmanship and extreme precision such as those of J. Richard, Voigtländer and Leitz have many users. The Reflex, both ordinary and folding, is a favourite for Nature study and other special work, and collapsible cameras, based on the original Goerz-Anschütz pattern, are very freely employed for Press photography.

The outstanding feature of latterday camera manufacture is the preponderance of instruments to take plates and films of the smaller sizes. Thanks to the "fine grain" of modern emulsion even negatives made with "vest-pocket" cameras will yield excellent half-plate enlargements. Naturally this facility appeals to the average amateur and also, in a measure, to professionals. In fact to-day the enlarger is complementary to the camera to such an extent that in any modern photographic exhibition the proportion of contact prints from negatives taken directly in cameras is conspicuously small.

Construction.—In some portable cameras the application of the "fixed focus" principle renders any focussing adjustment superfluous, but otherwise the latter is a primary constructional requirement. In the earlier field cameras the extension—almost invariably by means of leather bellows pleated accordion-wise—was regulated by an endless screw operated from the back. The method is still employed in big copying apparatus, but has been largely supplanted by a rack-and-pinion action, on the back of the camera if the bellows are parallel and racked out from the front, and on the front where conical bellows are racked out from the back. The front, sometimes the back also, is kept rigid by struts or other supports affixed to the baseboard, and the lens, usually mounted on a sliding panel, can be lowered or raised to modify the amount of foreground included. Convergence of vertical lines caused by tilting the camera can be corrected by a swinging back or front, which enables the base of the sensitive plate to be kept horizontal, and its sides vertical, irrespectively of the tilt. A "swing-back" or a "side-swing" is also occasionally useful for bringing into focus a foreground, or a near object on one side or the other of the subject, without "stopping down." Focussing is ordinarily carried out with stand cameras by viewing the image formed by the lens on the piece of finely ground glass constituting the *focussing screen,* a cloth being thrown over the camera to exclude extraneous light. In some cameras, notably those of the reflex type, a focussing chamber enables the focussing cloth to be dispensed with, and in most hand cameras the focussing screen is replaced by the finder (*q.v.*). For certain scientific purposes it is preferable to focus on a piece of plain glass with a focussing magnifier which thus virtually becomes the eyepiece of a telescopic system; but "aerial focussing," as it is called, is unsuited to ordinary photography in which composition of the subject as a whole must be studied.

The focussing screen, and, later, the dark slide or other receptacle for the sensitive plate or film is now usually held at the back of stand cameras in a frame which is reversible for pictures taken with the plate lengthwise or upright.

"Dark slides" to hold sensitive plates or cut films in sheaths are made to interchange with the focussing screen, the sensitive surface of the plate or film being in accurate register with the ground surface of the screen. Slides are commonly made to hold two plates or films back to back, with a metal partition to prevent the passage of light. There are two patterns, "book-form," hinged to open like a book, and solid, the latter generally known as plate-holders. With some hand cameras single metal slides are supplied. In all slides light is temporarily excluded from the front of the plate or film by a sliding or roller shutter which is removed or opened, of course, for exposure, and replaced or closed when the latter is completed.

In the case of *studio cameras* (*q.v.*) a "repeating slide" enables two plates to be quickly exposed in succession without removing the slide itself. In field cameras other methods are adopted, both to facilitate speedy consecutive exposures and to permit the carriage of a number of plates or cut films in less space than is possible with separate slides or plate-holders. Some patterns of changing-box are very compact and convenient. The usual construction is in the form of a box with a sliding door at the back, to the open top of which a small bag of light-tight material is affixed. The sliding door at the back having been removed the plates or cut films in sheaths are packed into the box, and a spring at the back ensures constant and even pressure upon all the sheaths in the pack, with the result that the front plate or film is always in register with the focussing screen. In the front of the box there is, as in the case of the ordinary dark slide, a shutter which is withdrawn for, and replaced after, exposure. The front plate after exposure is either lifted or levered up into the light-tight bag at the top of the box, and transferred with the finger and thumb to the back.

Slides, plate-holders and changing-boxes have largely been superseded for amateur use by roll-film cameras based on the Eastman Kodak system. In the earlier applications of the latter the roll of film was carried on a spool in a separate holder with removable back and shuttered front, which thus became a sort of changing-box. But the roll-holder is now incorporated in the camera itself, with appreciable increase of portability and convenience and no loss of efficiency. The film itself in a long strip sufficient for several exposures is backed by a longer strip of black paper on which at suitable intervals the number of the exposure is boldly stamped. The excess of black paper at either end of the film provides a safety covering during the process of loading the spool into the camera, and thus enables the latter operation to be performed in daylight. In practice, the lens being normally capped by a central shutter, the back of the camera is removed, and the spool inserted at one side of the roll-holding arrangement. At the other side an empty slotted spool should be in position. The seal of the full spool having been broken a portion of the safety covering is unwound and threaded into the slot of the empty spool. The back, which is provided with a small red "window," is now replaced. By means of a winder more of the black paper is wound off until the number (1) appears in the little red window. The section of film for the first picture is now in position, and exposure by operating the shutter follows.

An alternative method of daylight loading is provided by the film-pack system, originally introduced in connection with a special camera called the "Premo," but now adapted to nearly all classes of portable camera. The pack itself consists of a number of cut films with attached and interleaved pieces of black paper provided with numbered tags, the whole pack being backed by a sheet of metal provided with springs. By pulling out one of the tags a sensitive film is brought into position for exposure, the preceding film having been simultaneously transferred to the back of the pack.

With all hand cameras some form of *finder* is required. The earliest finder was a second camera, and this idea survives in twin-lens and binocular cameras. But the more usual finder is an attachment either of the "direct-vision" kind, with or without a lens or lenses, or in the form of an angled reflector in which an image produced by a miniature lens, and representing on a small scale that transmitted by the lens in actual use, is viewed,

either on the mirror itself, or on a tiny ground glass screen. The simplest form of direct-vision finder is a wire frame which, held at a correct distance, represents the proportions of the plate, the view included being identical with that photographed. In other direct-vision finders the subject is collected in a small rectangular negative lens, and this miniature image, accurately proportioned to the size of the plate, is viewed through an eye-hole or eye lens.

TYPES OF PHOTOGRAPHIC CAMERA

There are two principal kinds of photographic camera, studio and field, the former type a comparatively small category almost exclusively used by professional portraitists. The *studio camera* forms as a rule part of a combination (fig. 19), in which a substantially built stand, capable of adjustment as to height and inclination, is included. Such a combination should be movable to any part of the studio, preferably on casters. The camera is fitted with square bellows and focussing is by a double rack and pinion movement, sometimes supplemented by a draw-out extension for quickly obtaining a coarse focus. Extra rigidity is given to the fully extended instrument by a wooden centre frame. The front has a rising and falling movement and is very solidly built to carry large and heavy portrait lenses. In many cameras of this type there is an internal flap shutter which can be worked noiselessly by a bulb held in the operator's hand. Apart from portability the main difference between a studio and a field camera lies in the arrangement of the back.

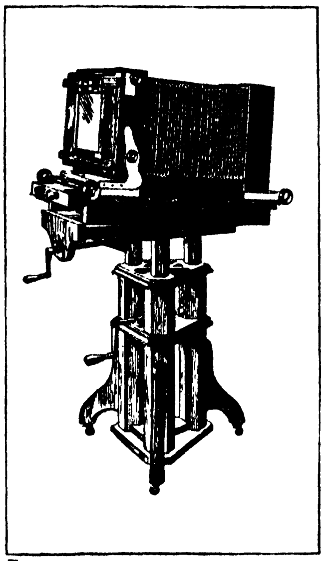

FIG. 19.—"ENSIGN" STUDIO CAMERA AND STAND

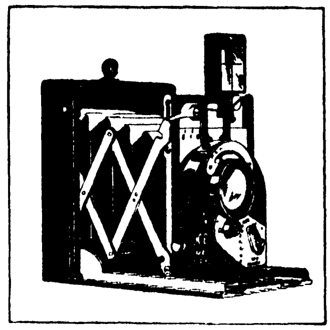
Field cameras are of many sorts and sizes and include several classes to which separate attention is being given. But the description "field" may be said to belong properly to the kind of camera used in the open, and on a stand, for general work which is not ordinarily attempted in the studio, such as large groups and *genre* studies in natural surroundings, as well as architecture and landscapes. Such a camera must be reasonably portable if plates of a fair size have to be exposed, and it should possess, in addition to a swing back (or front) and a rising and falling front, an extension sufficiently variable to enable lenses of relatively long or short focus to be used. Thus a half-plate camera, the lens normally employed with which would probably have a focal length of 8 in., should have a full extension of not less than 16 in. and it should be possible to rack it in to take wide-angle lenses with a focal length of not more than 4 in. As it is essential that a field camera should be quite rigid when fully extended the design of an instrument possessing this qualification, in addition to that of portability, presents some difficulties.

The "square-form" camera equipped with parallel bellows remains a favourite with many for field work, owing to its rigidity and adaptability to all classes of subjects and all types of lens. Only moderate portability, however, is possible with this model, and a rather substantial tripod is needed to support it at all satisfactorily. For sizes above half-plate, accordingly, a lighter form of camera with conical bellows is frequently preferred, and, provided that the design is good, and the material and workmanship all they should be, a field camera on these lines will meet all requirements. Only a well made conical bellows camera will carry a variable telephoto lens without risk of vibration, and for that particular branch of photography the "square form" is distinctly preferable. Some conical bellows models have baseboards in which a circle has been cut out and a metal ring inserted, thus constituting a tripod head to which ordinary tripod legs can be attached.

Owing to improved facilities for enlargement field cameras in the larger sizes are not now so freely used as formerly, and the convenience of roll film has rendered diminutive Kodaks, Carbines and other "pocket" instruments increasingly popular. But there is an intermediate type which, as an efficient compromise, is perhaps the most useful form of camera in existence. This is commonly known as the "hand or stand" variety, of which the Watson "Alpha" was the best early model. The later productions of Newman and Guardia, which owe their perfection chiefly to the mechanical genius of A. S. Newman, and those of Adams, the Houghton-Butcher Co., Ernemann and other makers, are modern examples of "hand or stand" design in which every conceivable requirement in the way of movement and extension is met in extremely portable instruments. In the "Sybils" (fig. 20) of the first named firm extra rigidity is secured by a neat and effective "lazy-tongs" method of extension. Another representative model of this type is the Sinclair "Una" which, while less compact than the "Sybil," is sufficiently portable and only a trifle less efficient than the "square form." The "Sanderson" of the Houghton-Butcher Co. is remarkable for the length of its extension, the latitude of its rising, falling, and swinging front movements, and the ingenious provision made for the use of very short focus lenses.



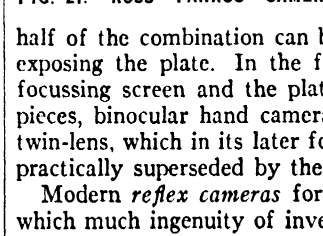
BY COURTESY OF NEWMAN & GUARDIA

FIG. 20.—NEWMAN AND GUARDIA "BABY SIZE" SYBIL

Collapsible hand cameras are largely used for Press photography. They form a type apart of which the Goerz-Anschütz was the pioneer model. A typical modern camera of this class is the Ross "Panros" (fig. 21) which is not only extremely convenient for hand work but can be so effectively used on a stand that it was adopted by the Royal Engineers for the field equipment of their Printing Companies, by whom it was extensively employed in the World War. Cameras of this kind are fitted with focal-plane shutters (*see* p. 828) and very rapid lenses, f/4·5 being a usual aperture. In the "Ermanox" made by the Zeiss Ikon Co. an Ernostar anastigmat working at f.1.8 has been fitted with which instantaneous photographs can be secured in a theatre with ordinary stage lighting.

Magazine cameras in which a number of plates or films are packed and brought forward successively for exposure, somewhat on the principle of the changing-box, are now comparatively seldom used. Unless of the simplest construction, in which case they are bulky, the changing mechanism is apt to give trouble.

Binocular and *twin-lens cameras* represent an endeavour to provide the operator with a view of the object up to and including the moment of exposure. They are literally, as their name implies, combinations of two separate cameras and two separate lenses, the focussing adjustments being correlated so that one half of the combination can be used for focussing, the other for exposing the plate. In the form of an inverted field glass, the focussing screen and the plate taking the place of the two eyepieces, binocular hand cameras are still to be met with, but the twin-lens, which in its later forms was an early "reflex," has been practically superseded by the single-lens reflex.



BY COURTESY OF ROSS

FIG. 21.—ROSS "PANROS" CAMERA

Modern *reflex cameras* form a class apart in connection with which much ingenuity of invention has been displayed and many patents have been taken out. The principle is explained in the accompanying diagram (fig. 22) but, as in practice the reflex is usually held in the hand, it is now fitted with a collapsible vertical hood which enables the operator to look down through it on to the focussing screen. A second mirror can, if desired, be fitted in

the hood for horizontal viewing, and focussing can be assisted by the use of a binocular focussing magnifier. Constructionally the reflex camera is a box containing a movable mirror interposed between the plate and the lens, and facing the latter at an angle of 45°. This throws up the image on to the horizontal focussing screen, on which it is viewed through the hood. The outstanding mechanical feature of the reflex is the co-ordination of the movement of the mirror with the shutter release. The removal of the former to enable the image transmitted by the lens to reach the plate, and the instantaneous exposure of the latter by means of the shutter, are effected simultaneously. The shutter almost invariably fitted to these cameras is of the focal plane type, and more than a dozen models of reflexes by first-class makers are available. A typical pattern of the reflex camera, with movable mirror, horizontal focussing screen and viewing hood is the "Soho" designed by Kershaw and made by the Amalgamated Photographic Manufacturers Ltd. (fig. 23).

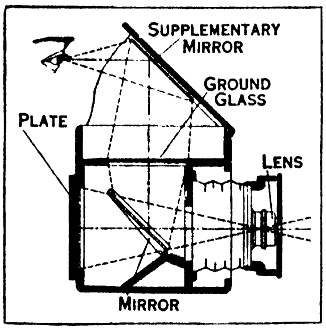


FIG. 22.—REFLEX CAMERA

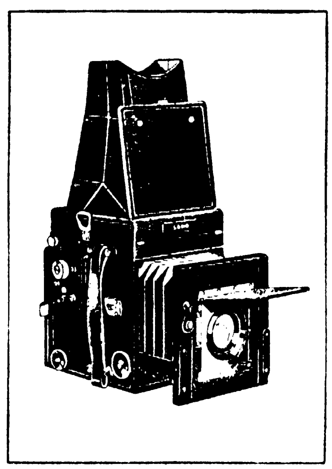
Reflex Camera and design and construction are considered by A. S. Newman in the *Photographic Journal* for 1921, p. 219.

The basic idea of the *Roll-film camera* has already been discussed. The folding Kodak (fig. 18) remains the most popular instrument of the type, and the latest models of it embody practically every improvement that ingenuity has devised or experience suggested. Substantially the form has not altered. The metal door which closes the front of the camera falls down and forms a baseboard along which the panel carrying the lens, shutter and finder are drawn out until the required focussing adjustment has been made. In some models the fixed focus principle is applied; in others the focus can be altered, according to an affixed scale, to suit all distances from a few feet to infinity. Great cleverness has been displayed in ensuring the rigidity of both baseboard and lens panel. In the better models a fair rise of front is allowed.

Focussing roll-film cameras, more or less closely resembling Kodaks, but containing various structural modifications, are now made by a number of British and foreign firms.

For *panoramic* photography various special types of camera have from time to time been introduced in order to satisfy the scientific requirement that, in covering the abnormally wide angles usually embraced in this kind of work, the lens should rotate on its nodal point of emergence. But practically all the earlier panoramic cameras, an account of which was given in the *B.J.A.* of 1892, have disappeared, and even the interesting and efficient little Panoram Kodak (fig. 24), which takes pictures on a section of roll film $3\frac{1}{4}$ in. $\times$ $10\frac{3}{8}$ in. with a lens swinging on its own axis through the arc of a circle, has comparatively few users. A few professional panoramic cameras, such as the "Cirkut" and the "Korona"—the latter made by the Gundlach-Manhattan Optical Co. of Rochester, U.S.A.—are available. But in modern practice panoramic photographs are commonly made by exposing several plates to cover sections of the complete picture.



BY COURTESY OF THE AMALGAMATED PHOTOGRAPHIC MANUFACTURERS
FIG. 23.—"SOHO" REFLEX CAMERA

Special cameras for *map reproduction*—often of huge dimensions—and for *copying* in connection with "process" work need not be specifically described as to all intents and purposes they are elaborations of the studio form. For *Colour Photography* (*q.v.*) various particular forms of camera and dark slide have been devised, more particularly in connection with the taking of the three negatives required for trichrome work on paper. The simplest method of obtaining the latter is separate exposure of three panchromatic plates in ordinary slides, the lens being screened successively by green, red and blue-violet filters. Greater speed is obtained by use of the Sanger-Shepherd repeating slide in which the three filters are placed immediately in front of sections of a long plate, the sections with their respective filters being exposed in quick succession by passing the slide along a frame fitted to the back of an ordinary camera. A modification of this repeating slide has recently (1928) been introduced by F. Newens. A more elaborate system consists in obtaining the three negatives at a single exposure by means of a specially constructed camera in which the image transmitted by the lens is trebled by the addition of prisms, one image reaching its plate directly, the other two reaching theirs by reflection. In some colour cameras the prisms are replaced by a mirror system, a recent example of the latter type being the special camera issued in connection with the Jos-Pe process. Numerous cameras of both types have been proposed, and are discussed in Vol. XLV. of the *Photographic Journal*, p. 150 (1905) by W. Gamble.

However, at the time of writing it seems very highly probable that the various specialized forms of the one-exposure camera for all of the varied applications of colour-photography will within a brief period of time be rendered obsolete. This important change in the technical practice of colour-photography will be inevitably brought about by the notable improvements in the application of the tripack method. In this new technique a single simultaneous exposure is given to three films packed together. One of these films is green-sensitive, another is red-sensitive, while the third film is blue-sensitive. By this ingenious combination, which greatly simplifies the problem of taking colour-pictures, noteworthy practical advances may be confidently expected throughout the entire field of colour-photography.

The construction of cameras for stereoscopic photography (*q.v.*) has reached a high degree of perfection in models such as the "Verascope" of J. Richard, the Leitz "Heidoscope" and the Voigtländer "Stereoflectoscope," the two last having a reflex finder in which a full size image is shown by the use of a third lens (fig. 26).

In the practice of *Photo-micrography* likewise, a large choice of apparatus is available, ranging from cameras of very long extension with elaborate arrangements for securing correct alignment to simple attachments for use with ordinary cameras for low power work. In addition to horizontal apparatus some fine cameras have been designed by Zeiss and others to work vertically, while others, again, can be used in conjunction with the microscope in either position.

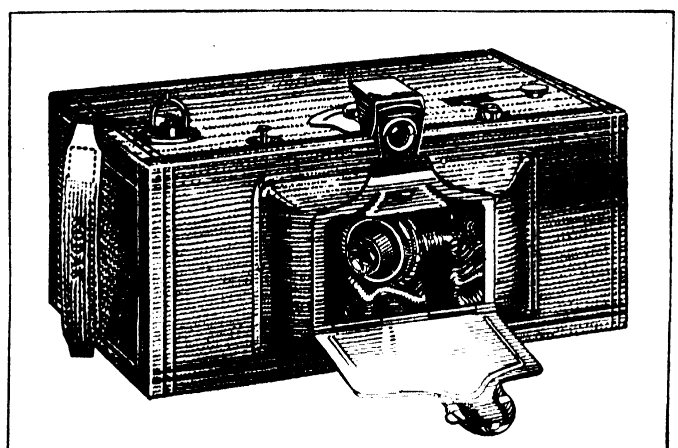


FIG. 24.—PANORAM "KODAK"

Since Cinematography, Aerial and X-ray photography are dealt with separately, the apparatus connected with them does not come within the scope of this Section.

FIG. 25 —ALDIS ENSIGN ENLARGER

Cinematography is dealt with under MOTION PICTURES (*see* especially MOTION PICTURE TECHNOLOGY by C. E. K. Mees). Aerial photography is treated under AERONAUTICS and AVIATION, also under SURVEYING. X-ray photography is discussed under X-RAY; X-RAYS AND CRYSTAL STRUCTURE and related subjects.

Enlargers.—The old method of enlarging by direct photography with a short focus lens and an ordinary camera of long extension has for a number of years been largely discarded in favour of the employment of apparatus resembling the ordinary optical lantern. In the modern enlarger (fig. 25) a negative or a transparency takes the place of the lantern slide, the screen being represented by an easel to which a piece of bromide paper or a sensitive plate is, after focussing, affixed. A powerful beam of artificial light is passed, with the help of a condenser, through the negative or transparency and the enlarging lens with the result that an image is projected varying in enlargement according to the distances between the negative and the lens and between the lens and the sensitive surface of the paper or plate. The illuminant may be either electric light or gas, but the former is now generally preferred, partly because it facilitates the construction of vertical enlargers which have some advantages over the horizontal form. A number of vertical enlargers have been designed.

Enlarging can also be carried out without condensers by collecting the rays of an illuminant in a reflector of ellipsoid form from which a parallel beam of sufficient size is passed through the negative. The latter may be held in the dark slide of an ordinary camera which, with its lens, is thus made to take the place of the front portion of an ordinary enlarging lantern.

The *Photostat*, an American invention introduced about 1907 and since greatly developed, is a combined camera and stand with semi-automatic mechanism for the reproduction of various kinds of official and commercial documents by unskilled operators in any ordinary well-lighted office. Any scale of enlargement or reduction can be adopted, and copies can be developed and fixed in not many seconds A very rapid colour-sensitive paper is used, rendering the system extremely valuable for copying engineers' and architects' plans, etc. See *B.J.A.* for 1928, p. 180.

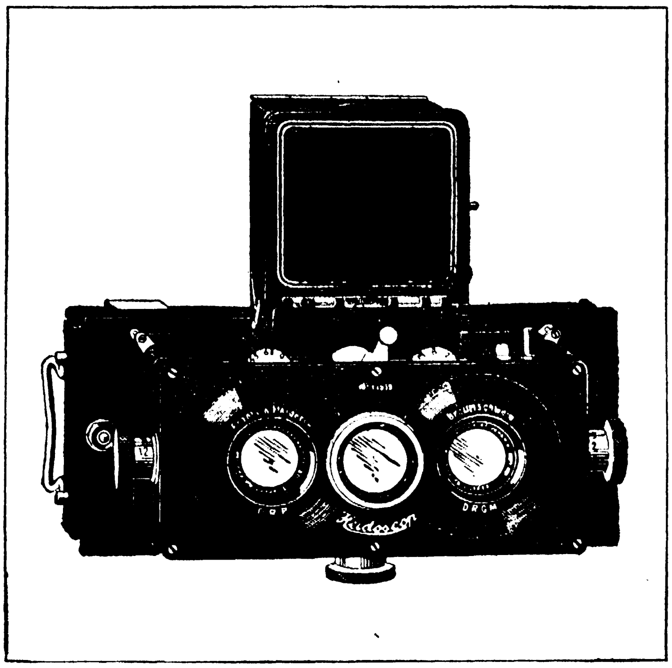
Stands.—For studio cameras (*q.v.*) as previously noted, stands of substantial "pillar" construction are usually provided With copying and other large cameras the stand is more often in the form of a table, but also provided with raising, lowering and tilting movements. For enlarging purposes the stand and easel are sometimes combined, runners enabling the conjugate distances to be readily varied. But for all general photographic purposes the tripod form of stand is the most practical, and almost innumerable patterns in wood and metal have been evolved For very small cameras tripods with telescoping legs of an aluminium alloy and a top of harder metal meet the demand for extreme portability, but for serious work a substantial wooden pattern is greatly to be preferred. The legs should telescope to make them not only more portable but also adjustable to uneven ground. For special work a revolving or tilting head may be desirable, and in some patterns provision is made for increasing the height of the camera from the ground by means of a second head raised on an adjustable rod above the normal level of the stand.

For steadying cameras for incidental snapshot work a "unipod" may be convenient. A unipod arrangement can also be employed to supplement the ordinary tripod as a support for a tele-

photo or other heavy lens affixed to a camera which is of frail construction.

PHOTOGRAPHIC LENSES

Historical.—The earliest form of photographic objective was an adaptation of W. H. Woolaston's single periscopic meniscus lens as applied by him to the camera obscura in 1812. This was achromatised by C. Chevalier for use about 1839 by Daguerre,



BY COURTESY OF OGILVY & CO.

FIG. 26.—"HEIDOSCOPE" STEREO-REFLEX CAMERA

but was not corrected for chemical focus. The first photographic lens corrected for chromatic aberration (*see* later under *Construction*), was a doublet made about 1840 by Andrew Ross for H. Collen, and consisting of two achromatic compounds, one at each end of a tube (fig. 27).[1] Many single lenses of good performance were produced by the early photographic opticians, T. Grubb's "Aplanatic" (1857) and J. H. Dallmeyer's "Wide Angle Landscape" (1865), "Rapid Landscape" (1884), and "Rectilinear Landscape" (1888) being notable examples.

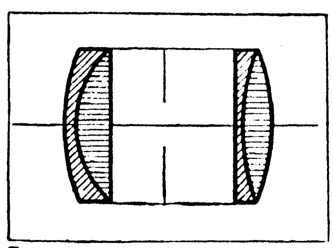


FIG. 27.—FIRST ENGLISH PORTRAIT LENS

In 1841 a remarkable advance was achieved by Voigtländer's introduction of a rapid portrait lens designed by Professor Petzval of Vienna (fig. 28), to whom is due the historic condition that the sum of the focal powers of the individual lenses in a photographic combination, multiplied by the reciprocals of their respective refractive indices, should be equal to zero, or $\Sigma \frac{1}{\mu f} = 0$. This pioneer portrait lens consisted of two dissimilar achromatic combinations widely separated, the front element being a plano-convex composed of a biconvex crown cemented to a plano-concave flint, while the back element was a double convex composed of a bi-convex crown separated by an air-space from a concave-convex flint. The form was notably improved by J. H. Dallmeyer who in 1866 reconstructed the back combination by substituting a meniscus crown for the bi-convex element, and a shallow concave-convex positive meniscus for the negative meniscus, reversing the positions, and introducing an air space.

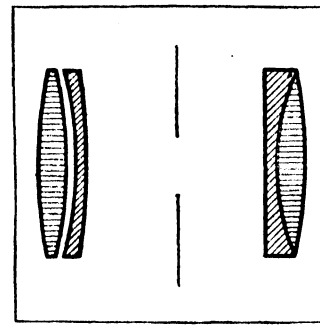

FIG. 28.—PETZVAL PORTRAIT LENS

In 1861 J. H. Dallmeyer produced a triplet very fully achromatised, non-distorting, and giving excellent definition, but since obsolete on account of its bulk and slowness.

Between 1841 and 1866 a number of doublets were brought forward by British and Continental opticians with the object of increasing rapidity and eliminating distortion, and towards the end of this period a simple and efficient type of "rectilinears," "symmetricals" and "aplanats" had become established. In the manufacture of these a high degree of excellence was attained particularly by Dallmeyer and Ross in England and by Steinheil in Germany (fig. 29). Wide-angle symmetrical doublets with greatly deepened curves appeared about the same time, some exhibiting remarkable qualities of definition combined with covering power. Dallmeyer's "Rapid Rectilinear," f/8 (1867) set what remained as the standard for photographic lenses for ordinary purposes until the perfection of the anastigmat. Among slower combinations the "Portable Symmetrical" of Ross was remarkable for its flatness of field and a compactness which enabled a number of lenses of widely different foci to be fitted into the same flange.

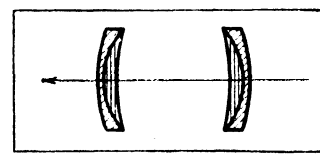

FIG. 29.—RAPID RECTILINEAR LENS

The issue in 1886 by Schott and Genossen of the "Jena glasses" formulated by Professor Abbe placed in the hands of photographic opticians a means of eliminating astigmatism by setting high refractivity with low dispersion against low refractivity with high dispersion. Some of the early Jena glasses were unstable and progress in construction was at first slow. In 1888 Dr. Shroeder worked out for Ross an anastigmat afterwards known as the "Concentric Lens" but the first thoroughly successful objective made with Jena glasses was that designed in 1889 by Dr. Paul Rudolph of the Zeiss firm, and classed as Series II. f/6·3. The details of construction are to be found in the *Eder Jahrbücher* for 1891 and 1893. This excellent lens was followed by several other anastigmatic singles and doublets, a new line being struck out by the symmetrical cemented doublet of C. P. Goerz known as the "Dagor," which has since been widely imitated. Almost simultaneously the single "Protars" of C. Zeiss came to be combined in doublet form. These improvements soon showed themselves to be as excellent in practice as they were in theory.

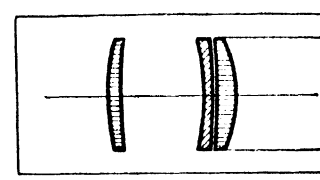

FIG. 30.—"COOKE" LENS, SERIES III

In 1895 Taylor, Taylor and Hobson produced a remarkable and entirely novel anastigmat designed by H. D. Taylor and known as the "Cooke" lens (fig. 30). It consists of three single lenses, a biconvex crown in front, and a very flat biconvex crown behind, with a biconcave of light flint in between, and close behind the front crown. Also in 1895 H. L. Aldis calculated for Dallmeyer a new convertible anastigmat consisting of two dissimilar compounds, thus giving a choice of three foci. The "Stigmatic," as it is called, is still issued but in a non-convertible form. In 1902 H. L. Aldis produced at the new works of Aldis Brothers at Birmingham a much simpler anastigmat composed of a

[1]In the diagrams of lenses which follow, a uniform system of indicating the nature of the glass employed by means of the shading has been adopted.

Flint glass is indicated thus:— 

Crown glass of low refractive power thus:—

Crown glass of high refractive power thus:— 

(These two are used indiscriminately in lenses made before the introduction of the new Jena glass.)

Extra light flint glass thus:— 

In most cases the front of the lens is on the right.

cemented meniscus in front and a single double convex back lens (fig. 31). Several series have been issued and very widely distributed. In 1902, again, Ross and E. Busch of Rathenow simultaneously produced anastigmats consisting of four separate lenses, the Ross combination, known as the "Homocentric," being of Jena glasses, while in the Busch "Omnars" as originally constructed normal glasses were employed. In 1907 H. C. and C. Beck made another new departure in the Isostigmar, remarkable as violating the Petzval condition, the inventor's theory being that the condition does not apply to lenses the individual elements of which are separated by large intervals (fig. 32). In 1913 J. W. Hasselkus worked out for Messrs. Ross a singularly fine anastigmat which has since become famous under the name "Xpres." It is a non-convertible doublet, the conspicuous feature of which is a cemented back combination consisting of three lenses, the first a biconcave or plano-concave of low refraction, the second a meniscus of medium refraction, and the third a biconvex of high refraction.

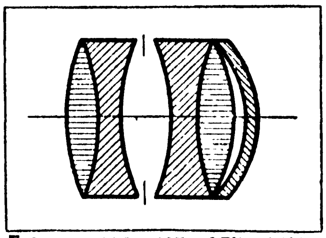

FIG. 31.—ASTIGMATIC LENS, SERIES III

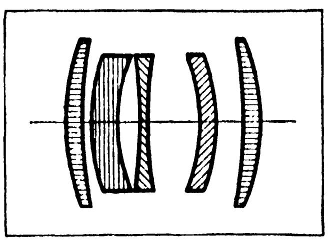
From 1898 in addition to the above-named, and in partial supersession of the doublets of Zeiss, Goerz, Steinheil and Voigtländer, there has been a steady stream of new lenses, mostly triplets—"Tessars," "Pentacs," "Serracs," "Heliars," "Aviars" and others—chiefly remarkable for increase of aperture but also of brilliant all-round performance (fig. 33). At the time of writing a high-water mark of rapidity seems to have been reached in a lens made by Ross for a special purpose to work at f/1·3, but there is also a prospect of reaction from such extremes and of a return to practical apertures, such as f/6·3, at which beautifully corrected lenses can be made of small dimensions and at moderate cost.



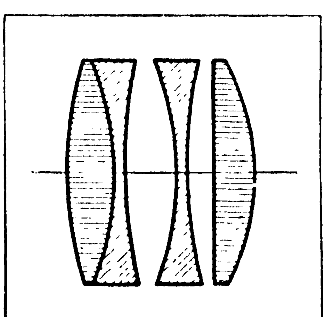
BY COURTESY OF R. & J. BECK

FIG. 32.—BECKS' "ISOSTIGMAR" LENS

In 1891 T. R. Dallmeyer in London, A. Miethe in Berlin and A. Dubosc in Paris simultaneously worked out telephotographic combinations consisting of positive and negative elements, variations in the separation of which produced magnification according to the camera extension employed.

CONSTRUCTION OF PHOTOGRAPHIC LENSES

The construction of technically good photographic lenses, of which some indication has been given in the preceding historical summary, depends largely upon the elimination of certain defects of which the principal are (1) Spherical aberration, (2) Coma, (3) Astigmatism, (4) Curvature of field, (5) Distortion and (6) Chromatic aberration. Spherical aberration is due to the fact that a spherical surface does not bend or focus light to one exact point, in other words the rays passing through the edge of such a surface do not focus to the same point as those passing through the centre. It can be partly corrected in a single lens by the use of a diaphragm, and in combinations by varying the curves of the component lenses. Coma and astigmatism are functions of spherical aberration, the first being a blur due to lateral spherical aberration of oblique rays. It is partly eliminated by the diaphragm. Astigmatism manifests itself in inability to focus accurately at the same time both vertical and horizontal lines near the margin of the field. It is partially cured by the use of a small diaphragm, and can be wholly eliminated by the selection of special glasses and the precise calculation of curves. Curvature of field is due to the failure of rays passed by a lens with a spherical surface to come to a focus on the same plane, the defect increasing, like astigmatism, with the obliquity of the rays. Here, too, the diaphragm can be of great service. Distortion is of two kinds, "barrel" and "cushion," a square appearing in the former shape if photographed with a single meniscus lens with the concave side outwards and the diaphragm placed in the front of the lens, and as a "cushion"—*i.e.*, with concave sides—if photographed with a single lens convex side outwards and with the diaphragm behind. It is corrected naturally in symmetrical doublets, since the barrel distortion of one component compensates the cushion distortion of the other. Chromatic aberration is caused by the dispersion of the white light passing through the lens, and is due to the fact that the different coloured rays come to a focus at different distances from the visual focus, according to their wavelengths. It is corrected by compensating lenses of different refractive powers. (*See* OPTICS.) In the general construction of photographic lenses the defects which were enumerated above, together with a number of others, are neutralized by regulating the curves of the different positive and negative component lenses, the refractive and dispersive indices of the glasses used, and the distances of the refracting surface, in this manner making the objective truly stigmatic or focussing to a point.



BY COURTESY OF CARL ZEISS

FIG. 33.—ZEISS'S "TESSAR"

The performance of an adequately corrected lens depends chiefly upon its effective *aperture* or the diameter of the clear ray actually used in impressing the image on the plate. This diameter is not necessarily that of the diaphragm employed, but the latter is used for the purpose of mechanical regulation of aperture, *i.e.*, reduction from "full" to the smallest possible. In early lenses the diaphragms or "stops" were of the Waterhouse pattern, with thin pieces of metal with circular openings of different sizes which could be inserted in a slot in the lens mount. This pattern is still employed in portrait and other large lenses. A variation is the rotating stop, a circular plate containing a series of apertures which can be brought into position as desired. Most modern lenses are fitted with iris diaphragms which Messrs. R. and J. Beck claim to have been the first to apply to photographic lenses in 1880. These consist of thin leaves of metal or ebonite so arranged that by operating a ring to which they are affixed apertures of different diameters can be formed at will. Several systems of numbering diaphragm apertures are in use, the most common being the F number method in which the aperture marked is the focal length of the lens divided by the effective diameter of the stop. Thus an effective diaphragm opening of ½ in. in the case of a lens of 8 in. focus would be f/16. In other words the aperture marked is a definite proportion of the focal length. Another system is the U.S., or Uniform Standard, proposed by the Royal Photographic Society in 1881 and adopted in the Kodaks. This takes f/4 as the standard, the markings corresponding to the F. numbers being as follows: f. values, f/4, f/5·6, f/8, f/11·3, f/16, f/22·6, f/32, f/45·2. U.S. Nos., 1, 2, 4, 8, 16, 32, 64, 128.

On the Continent the sequence of F. numbers is usually 3·16, 4·5, 6·3, 9, 12·5, 18, 25·3, 36, the exposure in each of the last seven cases being, as in the two preceding systems, double that which is found necessary in the case of the preceding number.

PROBLEMS OF FOCUS

The fact that *depth of focus* is conditioned not only by aperture but also by focal length has an important bearing upon the construction of very large aperture lenses. It is obviously of small use to build a cumbrous and costly lens with a focal length of, say, 12 in. and an aperture of, say f/3 for ordinary work, in which the lens would almost invariably need to be stopped at any rate to f/8 to secure reasonable "depth." But, with the extended use of diminutive cameras carrying very short focus lenses, the demand for very wide apertures has grown enormously, and

lenses working at f/3·5 are now comparatively common.

An important consideration in the construction of a photographic lens is the *angle of view* it embraces. If over 50° it is usually described as wide, if under 35° as narrow. The angle depends on the focal length of the lens in relation to the size of the plate, and in practice the focal length should not be less than the diagonal of the plate In the case of a half-plate this diagonal is 8 in, in that of a quarter-plate 5·3 in. Tables of view angles are published in the *B.J A.* showing the number of degrees embraced according to the quotient arrived at by dividing the diagonal of the plate by the equivalent focus of the lens. In the case of an 8 in lens used on a half-plate, the quotient arrived at being 1, the angle according to the table is 53°.

The term *focus* is explained in the general article on LENS (*q v.*), but it may be pointed out here that the equivalent focus of a photographic lens must be measured from the nodal point of emergence which is sometimes, as in the case of the Aldis and in that of Telephoto lenses, in front of the front component

The historical genesis of the principal forms of photographic lenses having already been discussed, their actual construction, apart from the optical considerations dealt with in the general article on LENS (*q.v.*), may now be glanced at. The single lens is seldom produced commercially to-day except as a component of a doublet or triplet, or in connection with the cheaper amateur outfits In the latter case it is a simple achromatic meniscus composed of a biconvex crown cemented to a biconcave flint The single components of the better types of "Rapid Rectilinear" are constructed in a somewhat different manner Anastigmat singles, such as those used to make up the combinations of the Zeiss "Protar," the Ross "Combinable," the Steinheil "Orthostigmat," the Watson "Holostigmat" and the Voigtlander "Collinear," are usually triple compounds of special Jena or Chance glasses. In addition to the symmetrical doublets formed by the combination of two simple singles there are a number of variously composed asymmetrical doublets, some with cemented, others with air-spaced components, are also notable combinations which, although assembled in two cells, are more or less frankly triplets. The Zeiss Tessars, which are entirely asymmetrical, consist of three separate components, that in front being a cemented lens, the other two uncemented, the intermediate one being a double concave In the construction of most modern doublets and triplets air-spaces play an important part (*See* LENS) Multiple combinations, such as the Beck Isostigmar, in some forms of which five separate lenses are used, are not in common use, although in the case mentioned a high degree of correction is attained

Apart from, or in connection with, their standard models some lens-makers have designed *supplementary lenses* to lengthen or shorten the foci of ordinary objectives. In their simplest form such lenses are either long focus negative or positive singles which can be attached to the front of an ordinary objective with, necessarily, some disturbance of the original corrections As far back as 1894 an advance in this direction was made by Taylor, Taylor and Hobson in connection with their "Cooke" lens by producing a suitably corrected rear extension lens for increasing the focal length. More recently the same principle has been applied by the Zeiss firm to its Tessars in a series of "Distars" and "Proxars," the former lengthening, the latter shortening the focal lengths of the original objectives.

The construction of telephoto combinations is altogether distinct from that of ordinary photographic lenses It is based on the fact that, if a negative lens is placed behind a positive lens at a separation not less than the difference between their focal lengths (which constitutes the Galilean telescopic condition), and not more than the focal length of the positive element, a photographic combination is formed, the focal length of which increases as the separation is decreased The "back focus," or distance from the back lens of the combination to the plate, is not, however, correspondingly increased, being dependent wholly on the focal length of the negative element, a very important consideration as it enables considerable magnification of the image transmitted by an ordinary lens to be obtained with the same or less camera extension. In 1907 Capt. Owen Wheeler introduced a system of combining tele-negatives to produce compounds of extremely short focal lengths, with which magnification up to X 30 is possible with a camera extension of only about 13 inches. A good feature of this system is that by making the rear lens of the combination one of relatively large diameter the covering power is greatly increased. Advantage was taken of this fact in a special complete tele-lens freely used by the Royal Engineers in the World War, which had a focal length of 30 in. and covered a 5×4 plate with a camera extension of 6 in only.

Originally telephoto lenses were "variable power" ones—*i.e.*, the separation of the elements could be altered at will to produce different magnifications with the same or with different tele-negatives. Also an ordinary photographic lens was generally used as the positive element. These arrangements were defective owing, firstly, to the disturbance of the corrections of the positive by a shifting negative element, and, secondly, to the comparative slowness of the combination due to the fact that the aperture of any telephoto lens is the aperture of the positive multiplied by the magnification Thus, in the case of a variable power combination in which, in order to obtain good definition, the positive is stopped to, say, f/11, the aperture at only 5 magnifications would be f/55.

Another drawback in the case of variable power combinations is their liability to internal reflections owing to the relatively long separation of the two elements. This is partially overcome by lining the lens tube with some non-reflecting substance or material, but a more effective plan is fit a *hood* on the lens to cut out the extraneous light—a method often adopted with advantage in the case of ordinary objectives. With high-power telephoto combinations hoods several inches long may be needed, and may be made with telescoping tubes

Variable power telephoto lenses are still used by specialists and extraordinary results are attainable with them But in modern practice single-focus combinations are much more common In these the positive element is a cemented single lens of extremely wide aperture, the defects of which are corrected in the negative element The earliest examples of this form were the f/9 Busch Bis-Telar (1905) and the f/14 Zeiss "Magnar" (1906), both since improved, but these have been put into the shade by recent productions of Ross, Dallmeyer, Taylor, Taylor and Hobson, Zeiss and others The principles and construction of the Telephoto Lens are discussed at length by H W. Lee in the *Photographic Journal* for 1925, p 392

TYPES OF LENSES

Little need be added here to the note in the historical summary above on the subject of *Portrait Lenses* It is a remarkable tribute to the genius of Petzval that the lines which he laid down in 1841 should be generally followed to-day in the lenses commonly used for portraiture, although naturally modifications and improvements have since been introduced by leading opticians. Ross, Dallmeyer, Taylor, Taylor and Hobson in Great Britain, and Voigtlander, particularly, on the Continent, have produced many portrait lenses of great excellence and, occasionally, of gargantuan proportions. In some modern studios, however, the portrait lens of old days is yielding place to the anastigmat, the wide aperture of which places it on a level with the Petzval construction in point of speed, while its more perfect corrections and covering power render it specially serviceable in the matter of studio groups In simple portraiture, on the other hand, extreme flatness of field is not always desirable, a round-fielded lens giving better "modelling" Since good portraiture has little use for "needle" sharpness of definition artist photographers since the days of Mrs Julia Cameron have sought in various ways to modify the critical rendering of objects in the same plane by a well-corrected lens. One method of producing "soft" effects is by means of the diffusion created by partly unscrewing one lens of a combination. Latterly soft focus lenses have been produced by several opticians in which diffusion is secured by special computation, the objective being duly corrected for flatness of field, distortion and colour, but yielding an attractively soft image of marked pictorial quality. A third soft focus method is the

employment of uncorrected lenses, as suggested by Bergheim, and carried out in the Dallmeyer-Bergheim lens (1895). Between 1903 and 1906 C. Puyo and L. de Puligny constructed several anachromatic systems for portrait and landscape work. More recently A. C. Banfield has experimented in the same direction with a view to keeping the aberrations in this form of lens within reasonable limits, the result being embodied in the Dallmeyer-Banfield Portrait Astigmat of focal lengths varying from 18 to 30 in. and working with a maximum intensity of f/6.

The variety of lenses in use for *field work* is so great that only a brief mention of a few leading models is possible. In these the reputation of the makers for design and workmanship is fully maintained, but it is fair to say that in many less well-known productions the requirements of all but specialists are adequately met, some important earlier patents having run out, and the supply of optical glass of high quality having been considerably expanded by the entry of Messrs. Chance of Birmingham into this field of manufacture. For all-round outdoor work the convertible cemented anastigmat is the most useful form, the performance of the single components in the case of doublets like the Zeiss "Protar," the Ross "Combinable," and the Watson "Holostigmat" being all that could be desired. With all these lenses asymmetrical as well as symmetrical combinations are practicable, thus giving a choice of three foci. In one series of the "Holostigmats" the single components can be used at the remarkably high aperture —for a single—of f/8·5. At the same time, the critical definition and increased rapidity possible with triple combinations like the "Tessars" makes them extremely popular, their usefulness being enhanced, where desired, by supplementary lenses such as those mentioned above. Of triplets and asymmetrical doublets, with components one or other of which is uncemented or a single glass, a wide choice is available from the lists of Ross, Dallmeyer, Taylor, Taylor and Hobson, Wray and Aldis Brothers in Great Britain, and of Zeiss, Goerz, Voigtländer and others on the Continent, the apertures ranging from f/2·2 to f/6·3 and the focal lengths from two to three inches up to as many feet.

In field work, more especially in connection with architectural studies in confined spaces, wide-angle lenses are often necessary, and much attention has been paid to this branch of lens construction both before and since the advent of the anastigmat. Of late years wide-angle lenses with comparatively large full apertures —very useful for focussing in dark interiors—have been made by Taylor, Taylor and Hobson, whose VII. B series, superseding their previous "Primoplanes," open to f/6·5 and at f/32 give sharp definition throughout a field of 100°. The Wide-Angle Aristostigmat of H. Meyer, the 4 in. model of which covers a half-plate at f/9, is another successful lens of this type. For the particular purpose of Aerial surveying, but also very useful for many other classes of work, a new wide-angle Ross Xpres, embracing an angle of 80° and covering sharply from centre to margin at the very high aperture of f/4, is a remarkable achievement, the report of the National Physical Laboratory on this objective showing extraordinarily good corrections. Where an abnormally wide-angle lens is needed the Goerz "Hypergon," which consists of two hemispherical lenses, and has a frontal star diaphragm to equalize the light, may be used to cover an angle of 135°.

Modern *Telephoto lenses* are, as previously indicated, very different from the early variable power type, and much better adapted to latterday requirements. The magnification is small, at the most X3, but this is compensated by critical definition enabling enlargement to be carried out to the same extent as with negatives made with ordinary objectives. For the modern telephoto lens is corrected throughout as carefully as the best ordinary anastigmat, being in fact itself an anastigmat, fully achromatised, free from curvature, spherical aberration and coma, and, within its limits, non-distorting. Also, as now made by half-a-dozen leading opticians, it is rapid enough for all practical purposes, even putting aside the latest "ultra-speed" models in which an aperture of f/3·5 has been reached. The only drawbacks are bulk and somewhat restricted covering power, but these do not constitute a high price to pay for a lens which will do very nearly all that the best ordinary lens will do at half the camera extension required by the latter. The most advanced lens of this type is the Ross Three Power "Teleros" which gives an image almost three times as large as that given by an ordinary lens from the same standpoint, and works at f/6·3. In the Two Power Teleros the aperture has been widened to f/5·5. There is also a Teleros of 40 in. focus, working at f/8, which is specially constructed for photographing cricket and other sports. Messrs. Dallmeyer, in addition to their "Grandac" and other variable power telephoto lenses, make a number of fixed-focus objectives giving magnification from X2 to 2½ and working at apertures from f/3·5 to f/7·7. The "Ultra-Speed Dallons" are only made in focal lengths up to 12 in. for covering quarter and 5X4 plates, but there is a very useful series working at f/5·6, the 24 in. model of which requires an extension of only 12 in. from the back cell to the focussing screen, and covers a whole-plate. Messrs. Taylor, Taylor and Hobson's "Cooke" Telephoto Anastigmats, Messrs. Wray's "Plustrar," the Zeiss "Tele-Tessar" and the Voigtländer "Tele-Dynar" are other fine examples of fixed-separation telephoto lenses. The "Cooke," like the "Dallon," is made with apertures of both f/3·5 and f/5·6, but with the former in two focal lengths, 8 in. and 10½ in., only.

In colour photography a high order of colour correction is necessary and for three-colour "process" and other colour work in which very great accuracy is essential it is desirable that the correction should be carried to the furthest practicable limit. This is done by means of special computations and glasses in *apochromatic lenses* made by Ross, Taylor, Taylor and Hobson, Zeiss and others. With a view to complete correction for colour a few quartz *lenses* have been made by British, French and American opticians, and further progress along that line may be looked for.

Lenses for cinematography receive mention in the article on MOTION PICTURES, but passing allusion may be made to them here since those employed in cine-cameras are photographic objectives pure and simple, made in most cases to standard formulae. Some extraordinary results have been attained in these tiny lenses, the Dallmeyer "Dalmac" having been adapted to cinematography in the 16 mm. sub-standard size in a variety of models, one of which has a focal length of 1 in. only, with an aperture of f/1·5. A number of tele-cine-lenses are also available.

Very short focus photographic lenses are also used in *photomicrography*, but are not so suitable for work at high powers as microscope objectives in conjunction with suitable eye-pieces.

ACCESSORIES

Light Filters.—The principles on which orthochromatism and panchromatism are based having already been explained (page 814), the discussion of light filters for cutting out some rays and emphasizing others need not occupy much space, although the subject, when closely considered, is of great scientific and technical interest. For the production of such filters various expedients have been tried, including small glass tanks filled with suitably coloured solutions, but in modern practice either specially coloured glasses or dyed gelatine strips cemented between glass squares or discs—preferably "optical flats"—are commonly employed. The making of gelatine "strip" for such filters demands some skill and patience, a perfectly levelled glass plate being required on which to spread the dyed gelatine solution. The latter must, of course, be as clear as possible, and stained a spectroscopically correct colour. A number of suitable dyes are available for making yellow and green filters, for use with orthochromatic plates, and blue (or violet), green and red filters, for panchromatic plates when the latter are employed in three-colour photography. Yellow filters are usually graded according to the extent to which they increase exposure. In addition to giving correct rendering of yellows and greens they are frequently of the greatest value in cutting out haze and enabling clouds and distant hills to be effectively reproduced.

Certain commercial filters, such as the Ilford "Gamma" and the Imperial "Impan," give accurate rendering of all colours when used with panchromatic plates from the same source of supply. The "Impan," by attaining this result, when used with

Imperial "Special B" panchromatic plates, with an exposure only $2\frac{1}{2}$ times that required without a filter, has set a new standard in this respect and greatly widened the application of panchromatism to hand camera work.

For the special filters used with Autochrome and mosaic screen plates *see* under *Colour Photography.*

Instantaneous Shutters.—The spread of the modern emulsions necessitates some means of opening and closing a lens in a fraction of a second. To this end a large variety of "instantaneous shutters" has been evolved. The earliest shutters were of the drop or flap pattern, the former merely an oblong strip of wood or metal, with an opening cut in it, and working in a frame fitted to the front of the lens. The dropping of the shutter through the frame effected the exposure by opening and closing the lens. The flap shutter, which is still used in the studio either on the lens or inside the camera, consists of one or two hinged flaps made to open outwards or inwards by either a pinion or a pneumatic ball and tube movement. Later, shutters were made to work between the lenses of a combination on either the rotary or iris diaphragm principle. In the former case a metal disc with an opening in it was revolved by means of a spring, in the latter leaves of metal or ebonite were made to open or close completely. The Goerz "Sector" and the "Georgen Central" were early shutters of this type.

Modern shutters are either of the roller blind or improved sector kind. Roller blind shutters are of two separate types, one in which the blind as a whole opens or closes the lens, difference in speed being obtained by tightening or relaxing the spring of the actuating mechanism; the other in which a slit in the blind passes behind the lens, the speed of exposure being governed partly by the tension and partly by the width of the slit. The ordinary roller blind shutters, of which the Thornton-Pickard (fig. 34) is the standard model, are, within their limits, very effective and dependable. Speeds from about $\frac{1}{15}$ to about $\frac{1}{90}$ sec. can be given by adjusting the spring, and a separate attachment to the bulb enables time exposures up to 3 sec. to be made automatically. The theory of such shutters is explained by Abney in his *Instantaneous Photography* (1895) and by W. B. Coventry in *The Technics of the Hand Camera* (1901). Of the focal-plane shutter, as the slit blind variety is called, there are numerous patterns geared and with adjustable slits to work at speeds from $\frac{1}{10}$ to over $\frac{1}{100}$ sec. The theory is explained by Coventry (*see* above) and by C. Fabre in *Traité encyclopédique de photographie,* Vol. 1, Suppl. C, 1902. This shutter works immediately in front of the plate and is normally built into the camera. The Goerz-Anschütz pattern is very typical of the entire group of focal-plane shutters. However, the focal-plane shutters embodied in several styles of cameras produced by British makers have special advantages in the matter of ease of adjustment and smoothness of operation.

FIG. 34.—MECHANISM OF THORNTON-PICKARD ROLLER-BLIND SHUTTER

The central lens shutter is now generally made with only two or three leaves or blades so constructed that practically the opening of all parts of the lens for exposure is simultaneous. Such shutters are made entirely of metal, and in the best patterns the mechanism is of the same precision as that of a watch. The exposure is effected by means of springs supplemented sometimes by an air-brake. A shutter known as the "Multi-speed" has been made to work between the lenses of a combination at speeds up to an alleged $\frac{1}{2000}$ sec., but in the best ordinary models a reputed $\frac{1}{300}$ sec. is the highest speed attainable. The speeds marked on central lens shutters are seldom to be depended upon, an exception being the "Newman-Sinclair Patent," which does not work at less than $\frac{1}{100}$ sec., but which will also give exposures as long as $\frac{1}{2}$ sec., the figures marked being absolutely trustworthy. *See* also *Photographic Shutters: Methods of Construction and Measuring their Speeds,* by A. S. Newman.

An alternative to the pneumatic shutter release is the "Antinous" or "cable" release consisting of a steel wire passing through a long chain of small steel beads. Pressure on a stud actuates a spiral spring, which, by its resultant action, produces either a "pull" or "push" movement in the shutter to which the release is affixed.

Exposure Meters.—There are now two main types of exposure meters, actinometric and visual observation, the latter commonly known as "extinction" meters. In the former sensitised paper is exposed to the light falling on the object, and the exposure is based on the time which the paper takes to darken to a certain tint. A narrow strip of specially prepared silver bromide paper which darkens rapidly on exposure to light is usually employed, a fresh section of it being exposed in juxtaposition with a fixed standard tint. The number of seconds, or minutes, counted before the standard tint is reached is called the actinometer time. This is correlated with the known speed of the plate and the stop in use, and the result read off on a dial. The leading British patterns of exposure meters are the Watkins and Wynne, both available in watch form. In the Watkins method plate-speeds are distinguished by numbers, in the Wynne meter by an F number, both designations being roughly comparable with the more precise H and D measurements. In "extinction" meters the visual intensity of the light reflected from the shadows is measured by direct observation. In many patterns, of which the "Heyde" is typical, the instrument is adjusted until the subject viewed in the meter appears to lose its shadow detail. In the more recent "Justophot" of E. Meyer (1924) the setting of the instrument is controlled by the moment of appearance of a small numeral as a bright figure in the centre of a dark field. (O. Wh.)

Developing and Printing Apparatus.—The apparatus used for producing finished prints from exposed sensitive materials differs according to the conditions under which the work is to be done. An amateur photographer who develops and prints his own photographs uses relatively simple apparatus. A portrait or commercial photographer is equipped to deal with larger sizes and to produce a larger output, while a trade finisher who develops and prints large numbers of films exposed by amateurs uses quite elaborate apparatus.

Plates and flat films are generally developed by amateur workers in flat trays, roll films in a special developing tank in which the film is held in the convolutions of a roll of celluloid which can be immersed in the developing solution. Sometimes plates are placed vertically in the grooves of a tank or of a rack which can be placed in a tank.

In connection with his factorial system of development (*q.v.*), A. Watkins produced in 1894 a factorial calculator and a dark room clock. With the later extension of "time and temperature" and tank developing methods, a number of dark room clocks and tanks of various patterns have been introduced, some of the former being provided with alarms which can be set to ring on the expiration of a given number of minutes, while others merely mark the progress of time on a dial with large hands.

For printing, the simplest method is to place the negative in a "printing frame" used to hold the sensitive paper in close contact with it during exposure to light. Pressure is usually by means of springs acting on the back, which is hinged to enable the progress of the printing to be watched in case printing-out paper is used. Even for amateur use, however, the replacement of other printing materials by developing papers has involved the general employment of simple printing boxes containing an electric light for which the current is controlled by a switch which is actuated when a platen is brought down on the negative and sensitive paper placed in contact with it.

Professional photographers develop their plates very largely in tanks, and the flat films, which to a considerable extent have replaced plates in professional work, are developed in holders which are placed in tanks and transferred from the developer to the fixing bath and then to the washing tank and finally to a drying cabinet. In this way a large number of negatives can be handled together and the day's work can be developed and made ready for printing very expeditiously.

Almost all of the printers used in professional work are of the printing box type, exposure being made to electric light operated when the platen is closed over the negative and printing paper. Professional printers are provided with attachments for masking the negatives and for the insertion of special masks of ground glass or celluloid on which local work can be done, so that parts of a negative can be printed to a lesser extent than other portions.

Prints are usually developed in large dishes and after fixing and washing may be dried either on racks covered with muslin or, if the output is very large, on one of the various belt driers.

Commercial photographs are often made with a glossy surface produced by squeegeeing the print on to a lacquered metal plate known as a "ferrotype plate" and are usually mounted in contact with backing cloth or paper in order to stiffen the print.

For mounting prints, a method of dry mounting by means of tissues which have been saturated with shellac is frequently adopted. Tissue and print are laid on the mount in the dry mounting press, in which heat is applied, which causes the shellac to melt, with the result that the print is cemented to the mount.

The business of "photo-finishing," as it is termed in the United States or "developing and printing" (D. & P.), as it is generally known in England, is now a very considerable portion of the photographic industry, many firms developing several million spools of amateurs' cartridge film every year. In the case of the large photo-finishers, the finishing plant collects film through the agency of a number of photographic dealers and returns the finished pictures to the dealers for distribution to the retail customer. Two important factors in the business are the short time in which it is necessary to get the work done, often 24 hours or less, and the great variation in the amount of business throughout the year, the output in England, for instance, being ten times as much at the maximum in August as at the minimum in January. This variation in the amount of business is causing great attention to be paid to the provision of automatic machines in order to diminish to a minimum the amount of skilled labor required. When the rolls of film come in, they are unwrapped in the dark room and numbered, the number being either punched into the film or light-printed on it. They are then held in clips which can be slipped over rods, so that the films with a weighted clip at the end are immersed in deep tanks of developer. After a fixed time of development, they are transferred to a rinse tank, fixed, washed, and again transferred to a drying cabinet.

Several forms of continuous machines have now been devised for developing the rolls of film. In these, the rods carrying the films held in clips are moved continuously by a conveyor system through a system of tanks and finally through a drying cupboard.

The dried negatives go forward to a printing room, where they are printed by contact upon developing paper, the printers being adapted for rapid operation, frequently by foot treadles, and equipped with numbering devices. Automatic power driven printers have been designed but have not yet come into general use.

From the printers, the paper goes to the developers, and at this stage also there is a tendency towards the use of machines of the conveyor type which carry the print through the necessary solutions and finally deliver them to a washer. Most prints, however, are developed in flat trays, fixed, and then washed in a rotating cage immersed in flowing water or in a series of flat trays through which water flows, this being used particularly in England, where it is known as a "cascade washer." The washed prints are dried by being placed between two fabric belts which travel over a heated drum, these machines being known as "belt driers," which deliver the prints dry within a few minutes.

Glossy prints are dried upon ferrotype plates in cupboards or, with the most recent machines, upon polished metal drums to which they are carried while wet by traveling belts.

The finished prints may be trimmed at the edges in order to give them a smooth finish and are usually delivered unmounted.

(C. E. K. M.)

Studio and Dark Room Appliances.—*Studio Lighting.*—Aside from furniture and blinds for adjustment of lighting by day a feature of most modern studios is the provision made for exposure by artificial light. Of the numerous effective systems in use some employ arc, others half-watt lamps in combination with suitable reflectors. Very serviceable special types of studio lighting apparatus have been evolved. A recently introduced studio lighting accessory is the "spot-light," borrowed from the stage.

Although seldom used in important studios the flash-lamp may be briefly mentioned under this heading. It consists of a pan in which a powder, usually composed largely of magnesium, can be ignited to produce a large flame of highly actinic quality.

Dark Room Fittings.—Mention has already been made of dark room clocks and of developing and bromide printing apparatus. In addition to these every year sees the introduction of new designs of lamps and other dark room equipment of sorts and sizes adapted to the nature and importance of the work in question. Of dark room lamps and lanterns in particular there is an endless variety, the most practical being those in which either white light or light which, while relatively bright, is "safe" for the plates in use, can be turned on at will. The incandescent electric lamp is naturally that chiefly used for such dual arrangements. To the making of different "safelights" suitable for all kinds of plates and bromide papers careful attention has been given, and, in order to cope with the extreme sensitiveness of modern emulsions, lanterns have been devised by Wratten and others in which only reflected light is proved through the safelight. This precaution, however, is being rendered superfluous by the new methods of desensitizing. While these methods are not sufficiently effective to enable very rapid panchromatic plates to be developed by naked candlelight, illumination is permissible after desensitizing which would formerly have been out of the question. In the autumn of 1928 the Ilford Co. introduced a new safelight for use with desensitized panchromatic plates, giving a pleasant green light by which development can be watched in comfort as well as in security.

PICTORIAL PHOTOGRAPHY

By pictorial photography we mean photography applied to the production of pictures in the accepted artistic tradition, but whether such pictures are to be admitted as art is a matter upon which the critics are still at variance. The subjects with which photography can deal most successfully are those in which realistic representation is permissible and not such as demand an imaginative treatment.

The Nude.—For that reason photography of the nude, which has always been a tempting subject, fails for the most part, not because it presents any greater technical difficulties but because the realism inseparable from photography makes it almost impossible to combine it with an idealistic conception, whilst it is equally difficult to use it convincingly in subjects drawn from ordinary life. To present the nude by photography simply as a study of the beauty of the human form involves firstly the finding of a model of perfect proportions and secondly extreme delicacy of artistic treatment to prevent degeneration into the recording of mere nakedness. In modern times this class of work is mostly done in the studios of the professional photographers who have greater facilities than the amateurs, but however excellent their work may be technically, it is usually quite meaningless from the artistic point of view. The finest use of the nude is to be found in the work of the Americans, especially those living in California where conditions are exceptionally favourable, and particularly in that of Annie Brigman, Arthur Kales and Walter Collinge

Still Life.—In other directions photography has more scope. Landscape, portraiture, domestic genre and still life all offer ample opportunities to the camera worker with artistic education and a trained eye. Still life, in particular, offers endless possibilities for imaginative treatment by photography and some very beautiful work of the kind has been done in the past by Baron de Meyer, J. M. Whitehead and E. Seymour. It is a branch of photography which the Japanese of the American Pacific coast have developed upon lines of their own in recent times, grafting the American love of startling eccentricities upon their own inborn sense of design. In their aptitude for seeing a pattern or decorative effect in chance combinations of the most commonplace kind they are unequalled. The exploitation of effects of pattern of an eccentric or sensational nature, if it did not actually originate in America, certainly reached its greatest development there some twenty years ago as a method of self advertisement. Such it still remains.

The sounder development of modern pictorial photography shows itself in a feeling for broader and simpler effects, in a stronger sense of pattern and in more attention to the form than to the content of the picture, in other words the picture is no longer expected to tell a story. As a graphic art, photography has certain disabilities, for it cannot suppress facts and cannot omit unwanted details at will. It can modify the presentation of the facts but any suppression or alteration has to be done by subsequent manipulations, usually involving handwork upon the negative or print, the legitimacy of which has been questioned.

IMPROVED PRACTICE

Fox Talbot.—The story of pictorial photography is largely bound up with the progressive improvements in the materials with which the photographer had to work. Fox Talbot's Calotype provided the first method of making pictures by the agency of light and so added photography to the graphic arts. In the year 1833 he was at Lake Como endeavouring to make sketches with the aid of the Camera Lucida but, lacking the necessary skill of hand, sought to devise a means of recording automatically the view as seen on the paper. After five or six years of experiment he was able to demonstrate his discovery of the process which is the basis of modern photography and two years later patented an improvement of this under the name of Calotype. He himself was a scientist rather than artist and it cannot be said that any of his surviving photographs show an artistic impulse.

D. O. Hill.—The first to put the new invention to a pictorial use was a Scottish artist, David Octavius Hill, who, having been present at the meeting at which the disruption of the Scottish Churches occurred, conceived the idea of painting the historic scene. It involved the inclusion of some hundreds of figures. To get sittings and draw all these portraits would have meant a year or two of labour and many might be dead before he could secure their likenesses. His friend, Sir David Brewster, an eminent scientist of the day, told him of the newly invented photography and at the same time introduced a young student of science, Robert Adamson of St. Andrews, to attend to the technical manipulations. For three years he worked at it and produced that series of portraits of Scottish notabilities that are amongst the greatest, as they are the earliest, masterpieces of the photographic art. An album containing fifty of the original prints of these was issued in 1848 and is now in the possession of the R.P.S.[1]

In 1846 Hill returned to his painting, became secretary of the Scottish Academy of Arts and died in 1870 so completely unknown to fame as a photographer that not a single photographic paper chronicled the event. Although references to his pictures occur earlier (*Photographic Journal*, 1854, vol. I., p. 177, also 1864, vol. IX., p. 63), it was not until James Craig Annan began to interest himself in Hill's work in the early nineties and published a series of photogravure plates from the original paper negatives, that he really became known.

It was Hill's artistry and not his photography that achieved greatness and it is well to bear this in mind when pictorial photography is twitted with not having done anything finer than Hill did so many years ago. Such a reproach is no more just than would be a similar one to the artists of today for not excelling Titian and Raphael and Michelangelo The "Girl in a Flowered Gown" is an example of the work of Hill.

Little is known of any of Hill's contemporaries. Dr. White of Aberdeen used photography for pictorial purposes and a collection of his landscapes was shown at the R.P.S. in December 1922 (*Photo. Journal*, vol. LXIII., p. 5) but the process was as yet so imperfect that the long exposures and lack of colour sensitiveness of the negative material made photography chiefly a recording medium for the scientist, whence arose the tradition of sharp uniform definition that distinguished its practice until the advent of Mrs. Cameron in 1864.

Albumen Paper and Collodion.—The introduction of albumen paper in 1848 and of the collodion process of Scott Archer in 1850 marked the next progression. Picture making was a serious business in those days when the negatives were made the full size of the finished print and had to be sensitized and developed in the field and when enlarging was as yet unknown. Already in the winter of 1851 there was a small group in London meeting regularly and by 1852 this had grown to such an extent that it was felt the time was ripe for a photographic society.

ROYAL PHOTOGRAPHIC SOCIETY

The First Exhibition.—The holding of the first recorded exhibition of photographers at the Gallery of the Society of Arts in December of that year gave an additional impetus and in January 1853 the Photographic Society of London came into being. Other societies quickly followed and photographers multiplied. At the first meeting of the London Society, one of the Vice Presidents, Sir William Newton R.A., a distinguished artist, read a paper in which he put forward several ideas that countered the false standard of pictorialism accepted as the result of its practice by those whose only qualifications were scientific.

The most admired features of a picture at that time, we read, were sharp definition all over and a blank expanse of pure white for the sky. Sir William made two suggestions that were a direct attack upon the existing position. One was that the pictorialist should aim at a broad and general effect for which end it was not necessary that the whole of the picture should be in sharp focus. The other was that artificial means should be adopted to obtain some suggestion of a sky, either by local reduction or by dabbing pigment on the back of the negative to simulate clouds. These rather ruffled the photographers but the leaven worked and by 1862 there was general agreement on the desirability of adding skies to pictures since it was then impossible to secure them on the same plate as the landscape. Already in 1856 a print

[1]Royal Photographic Society of Gt. Britain.

of a marine subject by a Frenchman named Le Gray exhibited at the Photographic Society's soirée at King's College had created a sensation and helped to break down the blank-sky convention.

Composites.—The next phase that developed naturally from the prevailing conditions was the production of composite pictures built up from two or more negatives. A method of doing this had been suggested as early as 1848 but the earliest exhibited example known was by Berwick and Annan in 1855 in which a figure had been introduced into a landscape. The first and most famous picture of this kind, of which we to-day have any knowledge, was "The Two Ways of Life" (R.P.S. collection). This interesting picture is a large print measuring 31x16 inches and built up from more than thirty separate negatives, by O. G. Rejlander, a Swede practising as a photographer at Wolverhampton. This remains the most ambitious attempt of its kind. Rejlander sent it to the Manchester Art Treasures Exhibition of 1857 where the original was bought for Queen Victoria. A second copy was purchased by Sir David Brewster who writes that he paid ten guineas for it, and a third copy, now at the R.P.S., was retained by Rejlander himself until 1870. There is no record of his making further use of the composite method although he worked for another twenty years, and all his other pictorial work is mainly in the class of domestic genre in which only one or two figures are used.

His example, however, stimulated Henry Peach Robinson (born at Ludlow in 1830), a young professional photographer at Leamington, to employ his leisure time in attempting similar methods of picture making. He had had some artistic training; he had carved one of the statues of the reredos of Ludlow church and one of his paintings was accepted by the Royal Academy before he was twenty-one. He started life in the bookselling business at Ludlow, Bromsgrove and London and whilst at Bromsgrove in 1850 learnt the daguerreotype process and subsequently Calotype and Collodion in preparation for a photographic career. His earliest pictorial attempts are unknown with the exception of the small "Juliet with the poison bottle" (R.P.S. collection) but in 1858 he produced a picture, entitled "Fading away," from five negatives which was first shown at the Crystal Palace and afterwards at Leeds. It excited a violent controversy on the permissibility of exhibiting so painful a subject (a girl dying from consumption) to the public gaze. Robinson's fame was thenceforward established and for the next thirty years he was the leader of British photography. His style was essentially Victorian, artistically sound but anecdotic. The principal idea was to make the picture tell a story. His three finest works "The Day's work done" (1877) "Dawn and Sunset" (1885) and "Carolling" (1887) are now preserved in the R.P.S. collection. The two former are magnificent examples of albumen printing, measuring 30x21 inches.

Further Inventions.—In the late 'fifties Pouncy's Gum Bichromate process and Poitevin's Carbon process were added to the existing printing media. The former received little attention but Carbon was developed commercially by Swan and the Autotype Co. and was taken up slowly by photographers.

A Notable Amateur.—The advent of Mrs. Julia Margaret Cameron in 1864 marks the next stage in pictorial development. The casual gift of a camera and lens by her daughter led her to take up photography at the age of fifty with all the volcanic energy of her temperament. She was one of a highly gifted family and had been closely associated with Watts and the painters of the Pre-Raphaelite school so that she brought an unconventional mind to the exercise of the new art. Her lens was of an uncorrected type and without waiting to learn the correct adjustments, she proceeded to use it in the manner that suited herself. She broke through all conventions and produced a series of heads distinguished by great breadth of modelling; indeed, in the case of the Carlyle and Herschell, by a violence of treatment that rather horrified the photographers of her time. The reviews of the exhibitions made some caustic comments on her methods (*Photo. Journal,* 1864. Vol. 9, p. 87. 1865. Vol. 10, p. 117) which were perhaps not altogether unjustified. She received, however, praise and encouragement from G. F. Watts and other men of discernment. As she was on intimate terms with many of the most eminent people of her day, her pictures have an interest beyond that of their artistic merits. The best of her work must certainly rank amongst the photographic masterpieces of all time. "The Guardian Angel" is one of her best known works. She was apt to be careless in her methods. Most of her original silver-albumen prints have now faded and were it not that her principal works were issued in autotype carbon, we could now hardly form a just estimate of her achievement.

Platinotype.—Willis brought out his Platinotype process in 1873 but it made little headway at first as a license was required to work it. Yet it fulfils the chief desideratum of the pictorialist in that it gives an image in permanent pigment on pure paper without the interposition of a gelatine or other film. The Oil Transfer process is the only other one that meets the same requirement. The next few years were occupied in the transition from the wet collodion to the dry gelatino-bromide plate and from albumen to the gelatino-bromide printing papers. Pictorialism shows no very marked movement during this period and it was not until 1888 and onwards that a new move was discernible. The dry plate and the invention of the hand camera were vastly enlarging the numbers who were being attracted to photography as a hobby and this very largely contributed to the advancement of pictorial work. The leading names at this time were Col. Joseph Gale, Frederick Hollyer, Frank Sutcliffe of Whitby, Payne Jennings, B Gay Wilkinson and J. B. B. Wellington.

THE NEW PICTORIAL MOVEMENT

Dr. Emerson's "Naturalistic Photography" (1887).—The expansion of a lecture by Dr. P. H. Emerson, "Naturalistic Photography," to the Camera Club in 1886, was the beginning of the new movement. Unquestionably this book struck a powerful blow at the many conventionalities which had attached themselves to the practice of photography and had a powerful influence upon the younger pictorialists. In it he lays down that, "naturalism is an impersonal method of expression, a more or less correct reflection of nature wherein (1) truth of sentiment, (2) illusion of truth of appearance (so far as is possible), and (3) decoration are of first and supreme importance." He further advocated the differentiation of focus to secure separation of the planes, closer attention to the rendering of "tone," greater adherence to truth through the study of nature and generally a higher and more intellectual standard.

To what extent Dr. Emerson's book contributed to the new pictorial movement that made itself evident in the late eighties is doubtful. The movement originated no doubt from the ferment in the artistic world due to the influence of the French Impressionist school which was becoming known and appreciated. The leaders of the new pictorialism were George Davison, Alexander Keighley, James Craig Annan, A. Horsley Hinton and Alfred Stieglitz, and the consensus of opinion is that the first visible sign of the break with the older Victorian tradition is to be found in Davison's picture "An old farmhouse" or, as it was called later, "The Onion field." This famous picture received the Photographic Society's medal in 1890. The council of the society consisted mainly of scientists who, beyond holding the annual Exhibition, did little to encourage pictorial work, and as a result the new body of pictorialists soon came into conflict with them.

There was a secession and many whose interests were purely pictorial left the parent society to band themselves together as "The Linked Ring" with definitely pictorial aims and interests, one of which was the holding of a separate exhibition to be known as The Salon. Although the society's neglect of pictorial interests was advanced at the time as the reason, the schism originated in a quarrel in which H. P. Robinson, Davison and the assistant secretary of the Photographic Society were involved. The establishment of this energetic new organisation brought about a veritable renaissance which received a further stimulus by the revival of Pouncy's Gum-Bichromate process in a workable form by Ladeveze, a Frenchman, and by Alfred Maskell and others in England. At last the pictorialists had a really controllable

printing process. Demachy, Le Begue, Puyo and others in France co-operated and our pictorialism took on a new orientation. Two of the finest pictures of this period are Horsley Hinton's "Melton Meadows" and Alex. Keighley's "The White Sail."

American Influence.—By the end of the century the first impetus of the movement was largely spent but a new era began in 1900 when F. Holland Day of Boston, U.S.A., exhibited at the R.P.S. house a collection of some 360 prints by members of the new American School. The exhibition proved a sensation and had a tremendous influence upon British photography, with the result that during the next six years pictorial photography reached a high level that it has never quite touched again.

The influence that was behind this wonderful American development was that strange genius Alfred Stieglitz, who after studying photography in Berlin, returned to New York about 1890 to begin his great task of building up an American School of pictorial photography upon foundations that were practically non-existent. The inspired achievements of the Americans from 1900 to 1908 are eloquent testimony to the success of his great work, for which in 1924 the Royal Photographic Society awarded him its Progress Medal, a unique distinction for a pictorial photographer. It is necessary to name only F. Holland Day, Yarnall Abbott, Gertrude Käsebier, Eduard Steichen, Frank Eugene, Clarence White, Alvin Langdon Coburn, Mrs. Annie Brigman and George H. Seeley to realise the number of photographers of real vision and genius who responded to the inspiration of Stieglitz.

Although the brilliance of the Americans overshadowed to some extent the work of the British school, that too reached a high level of excellence during the same period whilst its effort has been more sustained, so that in the subsequent twenty years British pictorial photography has taken more and more the leading position in the world's work, rather, perhaps, by reason of its sanity and sober pictorial excellence than by any quality of brilliance or progressive novelty of outlook.

The development of the colour sensitive plate, culminating in the Panchromatic plate in 1906, affected pictorial photography but little and even twenty years later, although most photographers use negative material that is orthochromatic to some extent, they are somewhat conservative in their attitude to panchromatics, principally because they are apt to give harsh results unless developed with more discretion than the average photographer possesses.

The introduction of the soft gradation Panchromatic plate by the Ilford Co. in 1928 may serve to break down this prejudice and get rid of the bugbear of "over-correction" which in most cases would be described more correctly as over-development.

The Oil Process.—A new method of printing, the Oil process, was introduced by G. E. H. Rawlins in 1904 and worked out by himself, Demachy in Paris and C. F. Inston in Liverpool. Based upon the action of light upon chromated gelatine, it consists in applying an oil pigment, such as lithographic or printing ink, to the damp gelatine surface by means of special brushes and so building up an image whose development can be controlled and modified according to the skill of the worker.

A very useful modification of this, known as Bromoil, was worked out by C. Welborne Piper in 1907. In this a Bromide print or enlargement is bleached in a special solution and can then be inked up in the manner described. The latest modification consists in transferring the inked image by means of pressure to a sheet of plain paper. This is the transfer process and bids fair to be the chief pictorial printing medium of the future, for the image then consists of a permanent pigment on pure paper, the whole process is under the photographer's control, and as many printings can be superimposed as may be necessary to secure the desired result.

PROGRESS OF PICTORIAL MOVEMENT

Great Britain.—In 1909 internal dissensions brought about the disruption of "The Linked Ring" and the exhibition of that year was the last of the original Salon. A few of the members formed themselves into a Secession which held a small but notable exhibition in 1910 which, however, was not repeated, and the other supporters of the Salon came together under the lead of F. J. Mortimer and established in 1911 the London Salon which still continues. Amidst all these changes the R.P.S. Exhibition continued its even way. For a year or two after the secession in 1892, the seceders held aloof but gradually they came back and most of the prominent pictorialists exhibited at both shows, so that there was little to choose between the two.

During the World War, and especially towards the end, pictorial photography was carried on under great difficulties and the Exhibitions fell almost to the vanishing point. Since then a gradual revival has set in but it has taken nearly ten years to return to normal. The feature of late years is the levelling up that has taken place in the work of the general body of photographers as well as the great increase in its practice. To the R.P.S. Exhibition of 1928, 460 workers sent in more than two thousand prints.

The position of British photography to-day is largely the result of the highly organized nature of its pictorial efforts, the very large number of photographic societies all over the Kingdom, their grouping into Federations and unions which cater for their needs and stimulate their activities, the scheme by which a large number of the societies are affiliated to the Royal Photographic Society for the same ends, and lastly the R.P.S. itself which has become not only the parent society of the British empire but, to an ever increasing extent, of the American and continental pictorial groups and associations as well. The numerous photographic exhibitions held in Great Britain, of which the most important are the R.P.S. Annual Exhibition, the London Salon, the exhibition of the Professional Photographers Association, the Salon of the Scottish Federation, the Northern Exhibition and the Midland Salon, have done much to foster the growth and appreciation of pictorial photography and afford the British public greater facilities to see good pictorial work than can be found in any other country.

America has several notable Salons held annually at Pittsburgh, Buffalo, Los Angeles, San Francisco and Seattle. The work there is inclined to be decidedly experimental and novelty is perhaps more sought after than beauty though this may be merely a stage in the development and the prelude to the evolution of a style and school such as was possessed in the great days before 1908.

France, under the inspiration of Robert Demachy in 1900, was the leader in photographic pictorialism but since the great men of that period retired from active participation in the foreign exhibitions, the French school is less known outside that country than formerly; although an exhibition of work by members of the French Photographic Society at the R.P.S. in 1926 revealed several new pictorialists of eminence.

Germany and Austria have, during the past thirty years, always held a prominent place in the pictorial movement with individual characteristics of their own. Before the World War the pictures of Duhrkoop, Perscheid, Kuhn and the large gum prints in colours by the brothers Hofmeister were notable features of the leading exhibitions. Since the World War the Germans have not participated to any great extent in foreign exhibitions, but the work of Otto Vogelsang of Pomerania, Dr. Koppitz of Vienna and Franz Drtikol of Prague has shown that there are pictorialists of the front rank.

Other Countries.—Italy has progressed rapidly in recent years under the inspiration of the *Gruppo Piemontese* of Turin and the work of the new school is virile whilst based on the best traditions. Spain possesses one pictorialist of eminence in J. Ortiz Echague but no national school, whilst in the Scandinavian countries the pictorial work appears to be done entirely by the professional photographers of whom Aage Remfeldt of Oslo and Ferdinand Flodin and Dr. H. B. Goodwin of Stockholm are the best known. In Holland and Belgium there are several active workers and Borrenbergen and Berssenbrugge in the former and Leonard Misonne in the latter are well known at the exhibitions in this country.

COLLECTION OF PICTORIAL PHOTOGRAPHS

The organized collection of pictorial photographs generally seems to have presented few attractions to any public institutions or to individuals, and it is a regrettable fact that no complete record exists of the achievements of the past. The importance to posterity of such a record was not realised in the early days and, in

any case, the housing and exhibition of such a collection would have presented insuperable difficulties to any body other than a municipal or government institution. Small individual collections have been made no doubt at all times but in only one or two cases could they claim any importance. The Duchess of Sermoneta is known to have possessed a fine collection but it is reported to have been dispersed at her death. Mr. Harold Holcroft of Wolverhampton has made a fairly representative collection of contemporary work during the past thirty years and this will be preserved intact as he has presented it to the Royal Photographic Society.

In the early days, the Prince Consort, who was keenly interested in photography, apparently formed a collection for in 1859 he offered fifty prints to the Photographic Society of London to form the nucleus of a permanent collection. The Society appointed a committee to consider the Prince's suggestion as it then possessed no permanent abode, and that apparently is as far as the matter ever went. If the prints were ever received there is no trace of them now. It was not until after 1890 that the idea of forming a permanent collection was revived and the line taken was to acquire annually the pictures which received medals at the exhibition but even that small effort soon expired and the collection grew in desultory fashion by casual gifts.

In 1923, however, the President, who for once was a pictorialist, organised an effort to make the collection worthy of the society. A ready response was received, many pictures of great historical and pictorial importance were secured, gaps were filled, a curator appointed and the Society's Permanent Collection, although by no means complete, is by far the largest and most representative in the world. The addition of the Holcroft collection adds greatly to its value and importance. Collections of photography have been made by the Smithsonian Institution, Washington, U.S.A., and by the State Museum in Berlin and in recent times Mrs. Milson, a former Lady Mayoress of Sydney, N.S.W. formed a collection of pictorial photographs to become the basis for a permanent collection in Australia, but none of these can compare in size and importance with the R.P.S. collection which contains examples of the work of all the most notable photographers from D. Ó. Hill to the present day. The further expansion of this collection is assured by the recent gift by Mr. Stephen H. Tyng of New York of a fund for the purchase annually of outstanding examples of photographic art. The administration of this fund is placed in the hands of the Pictorial Group of the R.P.S., an organization within the Society specially designed to encourage and foster pictorial interests in every possible manner.

Photographic Press, Weekly and Monthly.—This, while dealing with pictorial matters, has catered chiefly for the general reader and the publications dealing exclusively with pictorial interests have been comparatively few. The first of this nature in Great Britain was a series of monographs on the work of the leading pictorialists of the day, each volume being devoted to the work of one man and illustrated in photogravure by four of his pictures. The whole was issued in 1890 under the title of "Sun Artists." In 1895 the proprietors of *The Photogram*, a monthly magazine, issued a special volume devoted to an account of the photographic activities of the year in this and other countries, with 90 illustrations of selected pictures. This has grown to be a feature of annual interest and, under the editorship of F. J. Mortimer, F.R.P.S., is now the principal record of the photographic pictorialism of the world. A volume of somewhat similar aim but limited to the pictorial work exhibited at the R.P.S. has since 1926 been issued under the auspices of the Society by F. C. Tilney, F.R.P.S., who supplies a critical commentary on the pictures reproduced. In addition the Society issues in the October number of its *Journal* an account of the year's work both pictorial and scientific, with abundant illustrations. Of late years the *Société Française de Photographie* and the *Gruppo Piemontese* have issued sumptuously illustrated records of the Salons held by them annually, which constitute valuable records of the work done in their respective countries, and now Japan is doing the same on a slightly less ambitious scale in the *Japan Photographic Annual*.

The most beautiful of all these records of photography, however, we owe to Alfred Stieglitz who, in fifty-four volumes of *Camera Work* issued between 1903 and 1917, gave us the finest pictorial work of the principal masters in photogravure reproduction that are a joy to the connoisseur. This was the most perfect thing of its kind that has ever been attempted and involved Stieglitz in heavy financial loss in return for the devotedly unselfish labours of nearly twenty years.

In conclusion, pictorial photography would appear to have reached a point where no marked progress can be expected along the present lines and we await the coming of the genius who will give a new orientation to its aims. Perhaps the development may be in the nature of a direct colour process for with the addition of colour the scope of photography would be vastly widened.

SUBMARINE PHOTOGRAPHY

Water is often so calm and clear that it might seem easily possible for one above its surface to photograph fishes or other objects beneath it. This may, indeed, sometimes be done, but usually the attempt results in complete failure. The explanation is simple. At the moment of exposure the rays from the near submerged object are sharply focussed upon the plate. But at the same time more intense light from distant objects, out of focus, after being reflected from the water's surface reaches the plate also, which, when developed, consequently shows nothing. To set up an opaque screen shading the water's surface above the subject overcomes the difficulty. Through the shaded area, as through a window, one may photograph what lies below. However, the method is limited in its application. When the water exceeds 3ft. in depth it is usually better to use a submerged camera.

Dr. L. Boutan of Paris—pioneer in this field—between the years 1893 and 1898 attempted submarine photography at the Roscoff laboratory in Brittany with cameras of several sorts and appropriate and ingenious subsidiary apparatus. One of his cameras, made of metal, was directly submersible. Sea-water reached its interior, bathing both lens and plates. Although the result obtained was unsatisfactory because no thoroughly suitable lens was available, the principle seemed good to him. Other trials in which the camera was enclosed in and protected from the water by a metal box, through a glass window in which it looked out, were by comparison highly successful. This sort of apparatus, variously modified, has been used in all later work.

Boutan's cameras were of the simple detective type. Reighard, ten years after, at Tortugas, Fla., first used a reflecting camera protected in a water-tight box weighted down with lead till the window through which the camera looked was submerged, although the focussing hood remained above water and permitted him at all times to see what might be in the field. Excellent pictures were obtained within wading depth, beyond which he did not go.

Williamson Brothers, commercial motion photographers, probably as an independent invention, enclosed not only the camera, but the photographer as well, in a chamber suspended by a non-collapsible open tube from a floating scow. Perfect pictures of the sea bottom and animals in shallow water were obtained in the clear water of the Bahamas, as the scow stood still or was towed slowly along. These writers must be credited with the first attempt to secure a photographic record in colour of submarine life in its natural setting. By using selective filters they secured films which when projected upon the screen gave an idea of the variety of colour upon a tropical reef, but since the yellows registered as reds the attempt can scarcely be considered entirely successful.

Longley, with Reighard's apparatus reduced to manageable size and improved, having recourse again to diving equipment as Boutan had done, gave the submarine camera greater mobility and a wider range of usefulness. It now lends itself to instantaneous or timed exposures of any ordinary subject at moderate depths. In the tropics, where sunlight is intense, snapshots, it is interesting to note, may be taken as readily as upon land, but with somewhat longer exposure. Dr. Paul Bartsch, at Tortugas, and S. C. William Beebe, in Florida and the West Indies, have succeeded in obtaining pictures with a motion-picture camera similarly employed. Finally, Longley and Martin, working together and employing pound charges of flashlight powder set off electrically above water under a white cotton reflecting screen supported on pontoons by the same motion by which the submerged photographer exposed his plate, demonstrated the feasibility of submarine colour photography. The flash was so bright that even the slowly acting autochrome plate could be used for instantaneous exposures. Some of their photographs are reproduced in the article upon COLOURS OF ANIMALS.

PHOTOGRAPHY IN MEDICINE

There are three principal applications of photography in medical work, namely: (a) Radiography; (b) Photomicrography, and (c) Record photography, *i.e.*, the photographing of patients, specimens, apparatus, etc.

The last named section is a particular branch of technical photography and often the results obtained are unsatisfactory or even useless. This is usually because the camera is regarded as an automatic recording apparatus which can only give one impression of a subject. Hence when it is found that the original is reproduced in an unfamiliar form, with essential details unaccented and irrelevant ones exaggerated, it is naturally thought that the process is inefficient. The truth is that the camera will not discriminate between those details which are required and those that are not; but it is possible to accentuate the former by lighting, etc.

Neglecting for a moment the question of colour, a photograph reproduces in a series of tones the light reflected from the corresponding areas of the subject. If the exposure has been sufficient and the development adjusted to the printing paper used, this representation is correct over a considerable range. The conditions specified are not by any means always fulfilled and much of the failure of photographic recording is due to faulty technique at this stage. The range of tones is limited by the white of the printing paper itself and the black of the deepest deposit, which is about 20 to 1 and, if the intensities of the original subject cover a greater range, accurate reproduction is impossible in a print.

The compressing of an extended scale of tones into a shorter range is not very apparent but, on the other hand, there is a typical photographic distortion of the perspective which is often very noticeable. The perspective as reproduced by the lens of a camera is always mathematically correct but may yet appear unnatural to the eye. The explanation lies in the fact that to see the subject as the lens saw it, it is essential to look at the print from a distance equal to that which separated lens and plate when the exposure was made. The photograph which shows abrupt perspective was taken with a lens of short focal length and, if the print is moved up to that distance from the eye, the perspective will be seen to have become normal in appearance.

To avoid this distortion, it is clearly of importance to use a long focus lens. It is impossible to specify the exact length as that depends on the size of plate used. Such a lens is large and expensive and requires a camera with a long extension and plenty of room in the studio. An alternative method is to use a shorter focus lens on a small plate and make an enlarged print provided the loss in detail is not too great.

Another reason for the failure at times of the photograph lies in the difference between the eye and the plate in their response to light of different colours. An untreated plate is sensitive to the blue and violet end of the spectrum. By treating the plate with certain dyes, it has been found possible to extend the sensitivity first to the green and yellow (orthochromatic plates) and finally to the whole spectrum (panchromatic plates). The latter still retain their excessive sensitivity to the blue end of the spectrum and, in order to obtain a true rendering of the relative intensities of different colours, they must be used with their appropriate light filter. This consists of a piece of dyed gelatine usually yellow in colour placed over the lens.

In some cases, *e.g.*, faint reddish markings on the skin, a correct rendering would be unsatisfactory and here it is necessary to exaggerate the degree of contrast. An ordinary untreated plate, to which red is the same as black is to the eye, will give a more valuable if less correct photograph. Another case where increased contrast is desirable is when the print is to be reproduced by some half-tone process in a publication. The tones of the photograph are broken up into dots and the consequent reduction in contrast implies a somewhat harsher print.

THE PHOTOGRAPHING OF PATIENTS

In the photographing of patients, the most difficult problem lies in obtaining sufficient light. It is frequently necessary to stop down the lens considerably as parts of the subject will be at different distances and the aim of the photographer is a large scale photograph with good detail in every part. Again the slight movement due to breathing, etc., will be sufficient to spoil the finest detail if the exposure is at all prolonged. Hence on both counts, the light must be powerful. Daylight is variable and often not available. In cases where the patient can be moved into a studio, the most serviceable source of artificial light is a battery of large gas-filled electric lamps. The light is under control, any special lighting can be repeated and the volume of light is virtually constant.

Record work in the wards of a hospital is often of extreme difficulty owing to the weakness of the light. Here a magnesium flash lamp enclosed in a fabric bag can often be used. The exposure is practically instantaneous and the bag is afterwards removed and the smoke released outside the room. Care, however, should be taken not to use the apparatus when the slight explosion of the powder might cause distress.

When it is probable that a series of photographs will be required of a subject taken at certain intervals of time, it is most important that the conditions of lighting, position, etc., should not vary, so that the series may be comparable. Especially important is it that each photograph should be taken on the same scale. This is most readily ensured by measuring the distance from the front of the lens to the principal plane of the object and repeating this for the subsequent exposures.

To estimate the value of the degree of reduction, a clearly marked scale divided in feet or inches should be placed at the same distance from the lens as the principal plane of the object and in such a position that it is included in the photograph. The photograph of the scale is measured and the degree of reduction readily calculated.

With the object of making the records more comparative, it is of advantage to work with a series of standard reduction ratios, *e.g.*, $\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{2}$, etc. The distance lens-to-object is found for each ratio and then the camera placed at that distance and focussed.

The lens for record medical work should be a long focus anastigmat, capable of rendering the finest detail. Very big aperture lenses are seldom of much use in this work owing to their lack of depth of focus. The camera and stand should be rigid with a big range of adjustment. (B. D. H. W.)

PHOTOGRAPHY, CELESTIAL. The invention of photography by Daguerre in 1839 led to a great step in astronomical progress. The first application of the daguerreotype to the science was made by John William Draper of New York who photographed the moon on March 23, 1840, the exposure being 20 minutes. Experiments in the new method were made under the direction of W. C. and G. P. Bond at the Harvard college observatory, with the assistance of Messrs. Whipple and Black,

photographers of Boston, as operators, and the first photograph of the moon was taken there on Dec. 18, 1849, with the 15 in. object glass. A daguerreotype picture of the moon shown in London by George Bond at the Great Exhibition of 1851 attracted much attention.

Historical.—In England, Warren De la Rue, having seen the Harvard pictures, took up the subject and presented to the Royal Astronomical Society, in 1857, positive copies from a negative picture of the moon made by a collodion process that he had found practicable five years earlier. In 1864, Dr. Lewis Rutherford, of New York, made a telescope with object-glass of 11¼ in. aperture so corrected as to bring the photographic rays to focus. About the same time Dr. Henry Draper excelled his father's efforts by taking photographs of the moon with a 15 in. reflector, and early experiments in lunar photography, among them those by Hartnup of Liverpool, should not pass unnoticed.

It is said that the first photograph of a star was a daguerreotype of Vega taken at Harvard observatory on July 17, 1850, but want of sensitiveness made this process rather impracticable, and there was little success in stellar photography until the invention of the collodion plate that was used in America and England in 1852. In November 1857 a photograph of ζ Ursae Majoris with its companion Alcor taken at Harvard was sent for exhibition at the Royal Astronomical Society by W. C. Bond, an exposure of 80 sec. having been given to photograph the 6th magnitude star with the 15 in. refractor. De la Rue at this time was making experiments on the actinic power of Jupiter and Saturn compared with that of the moon, but his photographs did not show any details of the planetary surfaces. Under his direction also, and to his design a photoheliograph was made and set up at Kew observatory for the Royal Society, and the work of taking daily photographs of the sun, that has since been carried on successfully, at Greenwich and elsewhere, began at Kew in March 1858. In an attempt to photograph Donati's comet of that year, De la Rue was not successful though it was photographed by Usherwood, of Walton Common, in 7 sec. with a portrait lens of short focus.

Daguerreotypes of the sun taken by Foucault and Fizeau in 1845, and photographs of the solar eclipses of 1851 and 1854 were interesting as experiments, but the photographs taken by De la Rue and by Secchi of the total solar eclipse in 1860 were the first of this kind of real scientific importance, since they established beyond doubt that the solar protuberances were really appendages of the sun and not of the moon. Ten years later, at the eclipse of Dec. 12, 1870, excellent photographs taken by A. Brothers at Syracuse supplied evidence that the corona was also of solar origin; and from that time a photographic picture of the sun's surroundings has always been an item in the programme of eclipse observation. A series from 1896 to 1922 is published in the *Phil. Trans.* vol. 226 A, and as Appendix to vol. xiv. of the *Memoirs* of the Royal Astronomical Society.

In the years after 1870 research and experiment in photography generally were made by many, among these being the researches of Capt. W. de W. Abney, R.E., made specially for their application to astronomy. It was decided, mainly at the instigation of De la Rue, that photography should be used by the British expeditions in addition to visual observation for the Transit of Venus in 1874, and a considerable sum was granted for the expense of the work, which, so far as the process was concerned, was put in Abney's charge. He realized that the circumstances of the occasion would make a wet-plate process inapplicable and, after experiments conducted at Chatham, recommended the adoption of an albumen dry process, using a highly bromized collodion and strong alkaline development.

Without attempting to give any complete account of Abney's researches mention of the titles of two papers by him—*On Dry Plate Processes for Solar Photography* and *On the Photographic Method of Mapping the Least Refrangible End of the Solar Spectrum*—will indicate their bearing on astronomy. These papers represent a remarkable achievement in that Abney succeeded in producing a special photographic emulsion, sensitive to red light, which he used to map the solar spectrum far into the infra-red. The limit of Abney's measures at 9867A apparently was not reached by any other investigator until the introduction of neocyanin as a sensitizer in 1926.

It was pointed out by the younger Bond that photography might be successfully used to measure the relative positions of stars, of a group, or of double stars and in a letter to the Hon. William Mitchell, dated July 6, 1857, predicted, in effect, the application of photography to stellar astronomy on the magnificent scale that actually exists to-day. Rutherfurd, in 1864, began to make a long series of photographs of star clusters and of the bright double stars; but measures of these appear not to have been completed. In 1870–84 Dr. B. A. Gould in an expedition to the Southern Hemisphere accumulated negatives of the principal double stars and clusters; but in taking these series the wet plate process was used, and with this it was not possible to give an exposure long enough for faint stars to imprint themselves. With the invention of the gelatine dry plate, which had been used by Huggins for spectrum photography in 1876 and came into general use about 1880, this difficulty did not exist and modern astronomical photography became possible. Circumstances connected with the comet of 1882, which was specially magnificent as seen from the Southern Hemisphere, led to developments. A photograph, taken with a camera strapped for the purpose to the great equatorial of the Royal observatory of the Cape of Good Hope, showed not only the comet but great numbers of faint stars around it, and this at once gave David Gill, H.M. Astronomer at the Cape, the idea of the possibility of making star charts by photography. Effects of various kinds followed. At Paris the brothers Henry of the National observatory were engaged in the laborious task of plotting the positions of stars found by eye observation to make charts of the stars near the Ecliptic; but this work was abandoned and their efforts were devoted to making a telescopic object-glass suitable for photography. Ainslie Common in England turned to the art and with a three foot silver-on-glass mirror took a photograph of the Orion Nebula on Jan. 30th, 1883, with an exposure of 37 min., a feat that earned for him the Gold Medal of the Royal Astronomical Society in 1884, and was referred to as "epoch-marking" by Abney when presenting the medal to another non-professional astronomer for similar work eleven years later. A photograph of this object taken by Dr. Henry Draper of New York on Sept. 30, 1880 is said to be the first of a nebula obtained, but it is agreed that this was not a satisfactory representation. The later recipient of the medal above mentioned was Isaac Roberts, a business man of Liverpool, who in 1885, had made a 20 in. silver-on-glass reflector of nearly a 100 in. focal length for the purpose originally of making star-charts by photography, but altered his plans and devoted the instrument to photographing star-clusters and nebulae. The excellent pictures produced at his observatory at Crowborough, Sussex, are in two volumes published during his lifetime, supplemented by a third prepared and issued by his widow in 1928.

A copy of Common's remarkable photograph of the Orion nebula in the possession of Holden had much to do with the acquisition by the Lick Observatory in 1895 of the 3-foot reflector with which it had been taken. This mirror, made by Calven, was presented to the observatory by Mr. Crossley of Halifax, England, and the instrument is known by his name. In Keeler's hands it yielded a superb series of photographs of nebulae which for the first time demonstrated the great advantages of the reflecting telescope for certain classes of astronomical photography and led to the construction of the great modern reflectors.

Charts of the Heavens.—The advantage that photographs of clusters and nebulae have over visual observation is obvious. A glance at a photograph shows the whole of the object in all its beauty. The field of view of a telescope is small, and a complete conception of the nebula has to be built up from successive elements. It has already been mentioned that Gill foresaw the possibility of recording the positions of stars from a single plate; the next step was to connect individual plates to make a complete survey of the heavens, as had been, and is, the final aim and purpose of transit-observing. The first effort in this direction was made by Gill, who (1885–89), took photographs covering the sky from the South Pole to declination 18° S. which, measured by

Kapteyn of Groningen, gave approximate co-ordinates and magnitudes of nearly half a million stars that form the Cape Photographic Durchmusterung. In a more ambitious scheme initiated in 1887 by Admiral Mouchez, director of the Paris observatory, 18 observatories of the world combined to make the Astrographic Chart, or a picture of the whole sky, which should show all stars down to the 14th magnitude, to which was added later the making of a catalogue of all stars to magnitude 11, now considered the more important part of the work. Space does not permit description of its details and methods. It must suffice to say that a great portion of the catalogue is already published and that, though some sections of the Chart are completed, the end is not yet in sight.

In this connection mention is to be made of a series of plates that came later, taken by Franklin Adams, a man well known in business circles in the City of London, in 1903, 1904, at the Cape of Good Hope and afterwards at Godalming, Surrey, with a photovisual objective (*v.* p. 837) of 10 in. diameter, devised for the work by the firm of Cooke and Sons. These plates each cover an area of $15° \times 15°$.

The extreme delicacy of the gelatine film, especially during development and fixation, led in the beginning to a certain distrust of measurements made on photographic plates. Experience has shown these fears to be groundless and that photographic methods are well suited to measurements of the most exacting kind. With properly designed instruments, the economic factors are also favourable. A recent undertaking, proposed by Schlesinger, which effectively utilizes these advantages, is the photographic reobservation of the zones of the great Astronomische Gesellschaft catalogue, originally measured with meridian circles at many different observatories. As an early example of astronomical work effected by the measurement of photographs mention may be made of the determination of stellar parallaxes by Pritchard at the Oxford University Observatory in the year 1887, and the remark made at that time that this initiated a new method of finding the distances of stars is amply justified, for to-day many observatories are pursuing that plan. Most researches that depend on the measurement of small distances are now made by means of the photographic plate, close double star observing being an exception. Hertzsprung has devised methods involving the use of a grating and colour filters to ensure freedom from error in finding the distance between the components of double stars and their position angles, but it is considered that the photographic method is unsuited for pairs whose separation is less than about a second of arc. Photographing stars through a grating of parallel wires placed before the objective, which produces a pair, or perhaps a series of pairs of diffraction images of each star, is a scheme practised in other branches of modern astronomy and astrophysics.

Besides the advantages already mentioned, others that pertain to the sensitive plate are that its impressions are cumulative to an indefinite extent; it can see where the eye is blind. Its impressions are permanent and constitute evidence that can be referred to at pleasure. Faint comets are discovered by photographing the region in which the object is believed to lie and searching the developed plate. A similar method for finding minor planets has been very fruitful and examination of the series of celestial photographs of the Harvard College Observatory has brought to light many Novae that have appeared in past years but have escaped detection. This collection of photographs which has been accumulated systematically over many years constitutes a record of the state of the sky at approximately regular intervals. It has been especially fruitful in the discovery of variable stars.

Modern Applications.—Besides lending its aid to these branches of astronomy of the older kind, photography is now an asset in the newer astrophysics. It was recognized early that the brighter the star the larger the image it imprints on the plate, and hence that it is possible to use photography for purposes of photometry. The relation between the size of the image and the intensity of the star's light is complicated. So many factors difficult of control are involved that an empirical method of calibration is usually employed, though some progress has been made with methods based on the laws of photographic action. Usually a star is not of the same magnitude photographically and visually because the ordinary plate is sensitive only to the blue and violet rays of the spectrum, whereas it is the yellow light that mainly affects the eye. Since the relative amount of blue and yellow light depends on the colour of the star, the difference between photographic and visual magnitude varies with colour. This difference—colour index—affords a useful measure of this physical characteristic, and, through this, of the star's temperature. Visual magnitudes may be closely reproduced by photographing stars on colour-sensitive plates, through a filter which cuts out the blue and violet light and transmits the green and yellow. The whole field of stellar photometry is thus brought within the reach of photographic methods, with a great gain in precision and homogeneity of results. The equivalent of visual magnitude determined photographically is called photo-visual, and by comparing this with the ordinary photographic magnitude colour index is determined free from any personal eye effects. The colour index of a star correlates with its spectrum, and takes its place as a quality that can be discussed in relation to others such as temperature, mass and motion.

A slight extension of the method has led to interesting and important results in connection with nebulae.

A comparison by Hale of ordinary photographs of the Orion nebula with exposures on panchromatic plates through a red filter shows conspicuous differences in colour in different parts of the nebula which indicate a variation in the mixture and radiation of its gaseous constituents. Again, similar photographs of spiral nebulae by Seares show that the central nuclei of these objects are yellow, in agreement with spectroscopic results, but that the knots and condensations on the spiral arms are blue. These results indicate a characteristic difference in physical conditions in different parts of these nebulae.

Photography through coloured screens or filters of various kinds has been applied recently to the planets. Photographs of Mars and of Jupiter, by Wright of the Lick Observatory, taken with rays of the infra-red portion of the spectrum, with yellowy light, and with ultra-violet rays, show distinct differences, consideration of which appears to lead to knowledge of peculiarities of the surfaces and atmospheres of these bodies. Similar photographs of Venus by Ross give important information bearing on the physical characteristics of this planet.

Colour photographs of the kind described represent a crude kind of spectrum analysis, in which attention is directed to the total radiation over a considerable range in wave-length rather than to the number, position and intensity of the spectral lines. The method is important and useful for objects too faint for detailed spectroscopic examination.

The astronomical applications of photography would be seriously restricted were there no means of extending the normal blue-violet sensitivity of the ordinary photographic emulsion.

Vogel in 1873 discovered that various dye substances, notably naphtalinrot, conferred sensitiveness to other spectral regions. Vogel's results were confirmed and extended by E. Becquerel, by Waterhouse, who discovered the efficiency of eosin; by Eder, who introduced erythrosin; and by many others. Schumann announced the effectiveness of cyanin as a red sensitizer, and Valenta and Eberhard, 1897–1904, made extensive studies of a great number of sensitizers, which led shortly to the production of panchromatic plates. Dicyanin and, more recently, kryptocyanin and neocyanin have played a great part in extending the sensitivity far into the infra-red. All modern research in colour sensitization has been concerned with the study of dye substances. Abney's special red-sensitive emulsion seems never to have been reproduced.

The first great astronomical achievement resulting from the preparation of colour-sensitive plates was Abney's map of the infra-red region of the solar spectrum to which reference has already been made; the next, Rowland's photographic map of the solar spectrum and the Table of Wave-Lengths of Spectrum Lines, extending from 2975A to 7331A, from measurement of photographs. Rowland himself made the photographic plates that he used; the method of colour sensitization he employed is unknown. A recent application of colour photography to astronomy led to Hale's

iscovery of magnetic fields in sun-spots Using Wallace's 3-dye ensitizer consisting of pinacyanol, pinaverdol, and homocol, Hale hotographed with the spectroheliograph the distribution of hydro- en (Hα) over the solar disc. The presence of vortex structure entered about sun-spots suggested the possible existence of mag- etic fields, which special observations soon fully confirmed.

Spectroscopic observation itself is now almost entirely photo- raphic. In 1863 Huggins obtained photographic images of the ectra of Sirius and Capella but no clearly defined lines were own, and attempts of this kind were suspended for some years . is said that the first photograph showing spectral lines of a ar was taken by Henry Draper in 1872, and in the years imme- iately succeeding both these astronomers were successful in this ay with the brightest stars In 1882 each of them obtained a sat- factory photograph of the spectrum of the Great Nebula in rion. In 1886 a new spectrographic method was initiated at the arvard College Observatory in connection with a scheme known s the Draper Memorial, a prism being placed before the object- ass by which the spectra of *all* the stars in the field are formed d photographed simultaneously on the plate. The instrument en used was a photographic lens of 8 in aperture with a prism in. square fastened before it. The refracting angle of the prism as 13°, and the refracting edge was placed parallel to the equa- r, so that breadth could be given to the spectrum by altering e rate of the driving clock Stars to about the 7th magnitude ere thus shown In 1887 Vogel introduced the photographic ethod at the Astrophysical Observatory at Potsdam for the etermination of stellar radial velocity, and from that time, which generally said to mark the beginning of accurate work of the ind, all important spectroscopic work has been done in this way. nprovements and refinements in design of the spectrograph, specially the introduction of a temperature control for use uring observations, were made by Campbell at the Lick Ob- ervatory. These afforded a new standard of precision in ectroscopic measurements, and led to an extended programme volving the systematic observation, at Mt Hamilton and at antiago, of 6,182 stars mostly brighter than visual magnitude ·51 The resulting catalogue of radial velocities, issued in 1928, ould not have been prepared without the aid of photography.

Photographic methods have proved themselves equally indis- ensable in every other field of spectroscopic observation The easurement of the distance of a star from observations of its ectrum, by a method discovered by Adams and Kohlschutter nd developed by Adams at Mount Wilson, essentially requires e determination of the relative intensity of certain pairs of ectral lines Star light, in general, is far below the limiting tensity which would permit even the crudest visual observation f these intensities, and this is often true of laboratory sources f light which must be studied as a means of interpreting the bservations of celestial bodies Even for the sun, which gives an bundance of light, measures are most advantageously made on hotographs. In the infra-red and ultra-violet regions, outside the mits of visual perception, photographic methods alone are pos- ible. The novel instrument known as the spectroheliograph con- eived independently by Prof Hale and M Deslandres, director of he National Observatory, Paris, is an ingenious adjunct to spectral hotography. On a plate moving behind a second slit at the rear of spectroscope at the same rate as the image crosses the primary lit, or by an equivalent device the sun is photographed by the ght of a particular wave-length and pictures result which show he calcium or the hydrogen alone, in the successive envelopes of he sun, and so add vastly to our knowledge of its structure. The elp that photography brings to eclipse observation by making complete record of the spectrum of the chromosphere or of the orona in the very short time available on such occasions, that ay be studied at leisure, need not be dwelt on

Photographic Telescopes.—In the ordinary telescopic objec- ive the lenses are so shaped that the rays of the spectrum about he yellow are brought as nearly as possible to pass through the ame point as focus, for these are the rays to which the eye is ensitive; but for photography it is the blue and violet rays that ust be brought to a focus, for it is these that most affect the plate An objective of two lenses may be made to do this, but necessity has led to the making of photo-visual objectives of three lenses that are perfectly or nearly achromatic, and focus all the rays (*v.* p. 836, Franklin-Adams). It is possible to use a visual telescope for photography by adding a correcting lens, and another scheme for the purpose, adopted for the 40 in. refractor of the Yerkes observatory about 1900, is to take photographs through a yellow colour screen or filter placed almost in contact with the photographic plate, which is made specially sensitive to yellow light The yellow screen transmits freely to the plate the sharp yellow image produced by the visual objective and excludes the blue and other wave-lengths which would otherwise destroy the sharpness of the photographed images In the case of a reflector which brings all rays equally to the same focus this necessity for colour correction does not arise

In this particular the advantage of the reflector over the refrac- tor is very great. The field of view of the reflector, however, is relatively small For a focal ratio of 1 to 5 the aberrations of the reflector are disturbing at distances from the optical axis exceeding 12′ to 15′, and there is considerable loss in limiting magnitude for even smaller distances, whereas a properly designed refractor affords excellent definition over a field several degrees in diameter Measures with reflectors are therefore limited to double stars or satellites of planets, or to the determination of proper motions and parallaxes, etc , while the refractor finds advantageous application to general charting and cataloguing purposes

That the optical possibilities are by no means exhausted is indi- cated by the quadruplet lens recently designed by F. E. Ross which, with an aperture of 3 inches and a focal ratio of 1 to 7, gives excellent definition over a field of 25°, and in two hours exposure reaches a limiting magnitude of 15 4.

The choice of aperture and focal ratio for a photographic tele- scope depends on the purpose for which the instrument is to be used and is determined by the same principles that apply in ordinary photographic practice Increased focal length means in- creased scale or magnification in the photograph For a given focal length, increased aperture means greater brightness in the optical image, and hence greater photographic efficiency, which may be utilized either to reduce the exposure time or to photograph fainter objects than would otherwise be possible For extended objects like planets or nebulae, the brightness of the image is proportional to a^2/f^2. The photographic efficiency is independent of the linear dimensions, and the chief advantage of a large instrument is that of magnification At the same time, the instrument must not be too small, otherwise the power of resolution or minimum separa- tion which varies inversely as the aperture, will suffer For point sources, such as stars, the diameter of the central diffraction disc of the image decreases as the aperture increases This introduces an additional factor a^2, whence the brightness is proportional to a^4/f^2 For a given focal ratio there is in this case an important gain in efficiency with increasing aperture, although it is less than the elementary theory would indicate Aberrations and absorption and reflection losses in the objective, imperfections in the optical surfaces, and tremor of the diffraction disc, caused by atmospheric disturbances, all operate in diminishing the theoretical gain

The application of these principles to different classes of obser- vational problems is well illustrated by some of the instruments of the Mount Wilson Observatory For observations of the sun, both direct and spectroscopic, high magnification is desirable Since there is an abundance of light, the focal ratio need not be large, and, further, since a moderate aperture affords adequate resolution for photographic purposes, the dimensions chosen for the larger Tower telescope are $a=1$ foot, $f=150$ feet, with a ratio of 1 to 150 For the efficient photography of very faint stars, both the focal ratio and the linear dimensions should be as large as possible Hence in the Hooker reflector we find $a=100$ inches, $f=500$ inches, with a ratio of 1 to 5 Under favourable atmospheric conditions, the theoretical gain over the 60-inch reflector, of the same focal ratio, in photographing stars is very nearly attained. Aside from differences of scale, these two instruments are of equal efficiency in photographing nebulae. For planets, however, the 100-in is practically the more effective For the same magnification (enlarg-

ing lenses are commonly used in planetary photography) this instrument gives a brighter image than the 60-inch reflector. This permits the use of shorter exposures, which avoids in part the blurring produced by atmospheric disturbances. The useful field, the same for both reflectors, is necessarily small (*v.* p. 837). For photographs covering a large field, a triplet refractor is available ($a = 10$ inches, $f = 45$ inches, $a/f = 1/4{\cdot}5$). Because of the focal length, the scale is small. Otherwise, this instrument is of about the same efficiency for nebulae as the large reflectors, and because of the large field, is very advantageous for photographing widely extended masses of nebulosity. Its large focal ratio makes it an efficient instrument for stars, although the limiting magnitude attainable falls far short of that reached by the reflectors.

The limiting stellar magnitude attainable with a given instrument, as shown by F. E. Ross, does not increase indefinitely as the exposure time is extended. In order that a perceptible image of a star may be recorded, the contrast between sky illumination, which is always present in some degree, and sky illumination plus brightness of the central diffraction disc of the star image, must not drop below a certain minimum value. The effect of sky illumination is determined by the ratio a^2/f^2; with the reservations expressed above the brightness of the optical star image varies as a^4/f^2. Increase in the linear dimensions increases the latter, but not the former ratio. These ratios, together with certain photometric constants, determine the limiting magnitude attainable by prolonged exposure with any instrument. To photograph still fainter stars an instrument of larger aperture must be used.

The plate may be placed in the principal focus of the objective, and the image enlarged afterwards if desired; but the amount of the subsequent enlargement is limited by the grain of the original negative, which is equally enlarged by the copying process. On the other hand, a lens or combination of lenses may be interposed between the objective and the plate to give an enlarged image on the latter. In the Greenwich photoheliograph the image of the sun is enlarged on the plate in this way and the method is often used in planetary photography. For bright objects it is advantageous; but for fainter ones the exposures required may be impracticably long. The contrast also suffers, but this may be corrected by subsequent copying on plates of strong contrast.

In the early days of astronomical photography the inferior performance of the driving-clock of the equatorial was found to be a drawback, but this has been remedied, first by the introduction of electrical control and secondly by improvements in design and construction of driving-clocks, which are now of such perfection as to render electrical control unnecessary. The slight residual irregularities are eliminated by the use of the twin instrument consisting of two parallel telescopes of nearly equal size in the same frame, one of which is used visually by the observer to guide; or otherwise by the double-slide plateholder and duplicate guiding microscopes, to be used on two guiding stars on opposite sides of the field to detect the small rotation which may occur during exposures. (H. P. H.; F. H. S.)

PHOTOGRAPHY, SPARK: *see* SPARK PHOTOGRAPHY.

PHOTOGRAVURE (MACHINE). Photogravure (machine printed) is a photo-mechanical intaglio printing process. By this method prints are obtained from a plate or cylinder upon which the design is etched below the surface.

The subject to be reproduced is photographed and "reticulated" by means of a ruled screen, the "cavities" varying in depth according to the tones of the original; thus the solids are deeper and contain more ink than the middle tones, while the high lights are represented by the paper. The characteristic of this class of printing is revealed by its velvety depths and satin-like finish.

Machine photogravure was invented by Karl Klietsch, who, in conjunction with a firm of calico printers in Lancaster, produced prints by this method in 1895, although previous to this an employee of the firm, Samuel Fawcett, had been working an intaglio photo-engraving process of his own. The latter assisted Klietsch in perfecting the process now known as "Rembrandt" photogravure. The method of producing prints by the Rembrandt process was kept a close secret, and for many years those interested in reproductive processes had no authentic information as to how the printing plates were produced. In time, however, prints by similar processes were published, but these, at the time, were not equal to those printed by the Rembrandt process.

The principle of producing photogravure prints by machine is similar to that of printing calico and wallpaper, where engraved copper cylinders are used and printed on a rotary machine.

After the etching of the photogravure plate or cylinder has been completed the printing is of a mechanical character. The etched cylinder turns in a trough of printing ink of volatile qualities (sometimes a "water ink" is used), and as the cylinder rotates a fine steel knife, known as the "doctor," scrapes the surplus ink from the surface, leaving it clean. The cells or cavities, however, representing the tones of the design, retain the ink, which is transferred to a sheet of paper as it passes between the printing and impression cylinders.

Preparing the Printing Surface.—From the photographs of the subjects to be reproduced negatives are obtained. These are carefully retouched and reversed positives are made from them and, when necessary, again retouched. The positives—usually called transparencies—have then to be "planned" or laid out, *i.e.*, fixed by means of gummed tape upon a sheet of plate glass in the positions in which they will be printed.

A carbon print is next obtained on what is known as "carbon tissue" (a sheet of paper coated with a gelatine solution to which has been added a pigment—usually red—and sensitised by immersion in potassium bichromate, squeezed on to a sheet of glass, and dried). A piece of carbon tissue is cut slightly larger than the positives and placed along with the positives in a special pneumatic printing frame from which the air is extracted, thus bringing the positive and tissue into close contact. These are exposed to light, the positives are removed, and another exposure is given to the tissue through a specially ruled screen. The screen "breaks up" the tones of the photograph and provides the reticulation which is necessary for all printing processes. The usual ruling of the screen is 150 or 175 lines to the inch. The carbon tissue is next soaked in water and placed on the copper plate or cylinder which has previously been made chemically clean and free from grease. The tissue is then "squeegeed" in order to remove all moisture and air from between the tissue and the printing surface, which is then dried.

Developing.—The next operation is known as developing, and is done by placing the cylinder or plate, on which the carbon tissue has been fixed, in a tank of water heated to about 104° F and kept agitated until the paper is soaked off and the soluble parts of the gelatine film washed away. The parts where the light passes right through the positive become hard and are insoluble, whilst those parts where the light is retarded by the tones in their various gradations are more or less soluble.

When the development is completed the cylinder, with all that is left of the gelatine film, is removed from the water bath and thoroughly dried. This film acts as a resist to the mordant. All parts of the printing surface which are not required to be etched are protected by an acid-resisting preparation. This is painted on by hand, or, as it is termed, "lacked out."

Etching.—The printing surface has then to be etched, which is done by placing the cylinder in baths of varying concentrations of ferric chloride ranging from 45° to 37° Beaume. The thinner parts of the hardened gelatine acid resist are attacked first by the mordant, the thicker parts requiring further etching by the weaker solutions.

It is possible to use the copper cylinders over and over again, the old work being removed by grinding and polishing. In this way cylinders are prepared to receive the new work. In time, however, the grinding wears the cylinder, but this may be brought back to its original circumference by electrolytic deposition.

Machines.—Sometimes flat plates are used. In this instance the machine is of an ordinary flat-bed type upon which a plate is mounted on a bed and covered over with ink, the "doctor" scraping the surplus ink from the face of the plate back into the trough; the general method, however, is to employ cylinders.

Recently, a method has been invented whereby a thin sheet

of copper is stretched round a cylinder. There is reason to believe that this will supersede the cumbersome cylinders now in use

The paper is fed into the machines either one sheet at a time or from a reel. The sheet-fed machine is generally used for small editions of art reproductions, whilst those that are reel-fed are used for long runs of magazines and newspaper supplements and other commercial requirements.

In a rotary press the cylinder revolves in a trough of ink, and a few inches above the trough is a "doctor"—a steel plate with a fine edge which has a slight reciprocating movement that scrapes the surplus ink off the surface, the ink dropping back into the trough. The paper, which is on a reel, passes between the etched cylinder and an impression cylinder In this way an impression of the etched design is transferred to the paper The paper then passes over a drying drum, and if the sheet is to be "perfected," *i e*, printed on the reverse side, it goes through another pair of cylinders before reaching the delivery end of the machine, where the paper is cut up into sheets or delivered folded according to requirements

It is possible by the photogravure method to print type matter at the same time as illustrations, and successful results are now being obtained when printing colour supplements by machine photogravure

Machine printed photogravure is known under various names, usually containing a prefix, such as rotogravure, indicating that it is printed on a rotary machine

See PHOTO-ENGRAVING, COLOUR PRINTING.

BIBLIOGRAPHY.—Thos. Huson, *Photo-Aquatint and Photogravure* (1897), a practical treatise on the preparing and printing of intaglio plates; Colin N Bennett, *Elements of Photogravure* (1926), a publication useful to photographers, etchers and printers (J. R R)

PHOTO-LITHOGRAPHY: *see* LITHOGRAPHY

PHOTOMETRY is, as its name signifies, the measurement of light (Gr. φῶς, φωτός, light, μέτρον, a measure) Just as metrology includes the measurement of various related quantities, *e.g*, length, volume and density, so photometry includes the measurement of luminous intensity (candle-power), luminous flux, illumination and brightness. It will be convenient first of all to consider the relationships between these four fundamental quantities and the units in terms of which they are expressed, so that the methods of measurement adopted for each may be more readily understood Every object which can be seen emits or reflects radiant energy in the form of aether waves which are capable of affecting the retina of the human eye so as to produce the sensation of light In the case of a self-luminous body (or source of light) such as the sun, a candle or an electric lamp, the light emitted is obtained by the transformation of some other form of energy, generally chemical or electrical In the case of a body which is not self-luminous the light which it sends to the eye is derived originally from some self-luminous body, and is reflected by it in a manner depending on the character of its surfaces.

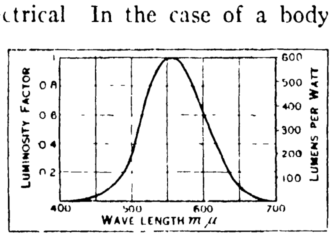

FIG 1 —LUMINOSITY CURVE OF RADIANT ENERGY FOR THE AVERAGE EYE

The effect produced on the eye by the reception of a given amount of energy per second depends on the wave-length (λ) of the aether waves by which that energy is conveyed, in fact only those waves for which λ lies between about 400 and 750 millionths of a millimetre $m\mu$ can produce the sensation of light at all As the wave-length changes from the shorter of these limits to the longer, the effect produced on the eye alters in two respects In the first place the colour of the light changes from violet, through blue, green, yellow and orange to red. In the second place the intensity of the sensation produced by a given rate of influx of energy starts from zero at 400 $m\mu$, rises to a maximum at $\lambda = 555$ $m\mu$, and then gradually falls away again to zero at 750 $m\mu$ The curve of fig 1 shows the relative magnitudes of the visual effect produced by the reception of equal amounts of energy per second at different wave-lengths. This curve is called the *luminosity curve* (sometimes the *visibility curve*) of radiant energy. It is naturally slightly different for each individual, but the curve shown is that now adopted internationally as representing the effect on the "average eye" The scale of ordinates at the left is an arbitrary one so arranged that the ordinate of the curve is unity at the wave-length of maximum luminosity On this scale the ordinate corresponding to any wave-length is termed the "luminosity factor" of radiant energy at that wave-length.

Luminous Flux.—The light given by every source in common use is composite in character, *i e*, the energy is conveyed by waves of various lengths, the distribution of energy among these wave-lengths (or the *spectral energy-distribution*) depending on the source It is clear that the total effect produced on the eye by a given rate of emission of energy of known spectral distribution can be determined by weighting the energy content at each wave-length in accordance with the *luminosity factor* for that wave-length The quantity obtained in this way represents, in fact, the efficacy of the energy for producing the sensation of light, and this quantity is termed *luminous flux* The formal definition of this term is. The rate of passage of radiant energy evaluated according to the luminous sensation produced by it

The unit in which luminous flux is expressed can be more simply defined later It is sufficient here to state that it is called the *lumen* and that it has been found that for the average eye, one watt of radiant power at the wave-length of maximum luminosity (555 $m\mu$) is equivalent to about 600 lumens The scale of ordinates at the right of fig 1 gives the lumen equivalent of 1 watt of power at each wave-length The watt equivalent of 1 lumen of flux at the wave-length of maximum visibility, viz, 0·0016 watt per lumen, is often termed the *mechanical equivalent of light*

Luminous Intensity.—The luminous flux emitted from any practical source of light is not distributed uniformly in all directions In the case of an electric lamp of the vacuum type, for instance, the flux emitted within a cone of given solid angle is greater when the axis of the cone is horizontal than when it is vertical It follows that some quantity is needed to express the light-giving power of a source in a specified direction The natural quantity to use for this purpose is the angular flux density in the direction considered This will be clear from fig 2 If BLC be a cone of very small solid angle ω, having its apex at L, the position of a source of light, then the angular flux density in any direction such as LA is equal to the flux emitted by L within the cone BLC, divided by the solid angle ω, the ratio being taken in the limit when ω becomes vanishingly small This ratio is termed the *luminous intensity* of the source L in the direction LA It will be seen that the definition of luminous intensity is analogous to that of pressure at a point, viz, the ratio of the force exerted on a given surface containing the point to the area of that surface, the ratio being taken in the limit when the area is vanishingly small The formal definition of luminous intensity is as follows —The luminous intensity of a point-source in any direction is the luminous flux, per unit solid angle, emitted by that source in that direction (The flux emanating from a source whose dimensions are negligible in comparison with the distance from which it is observed may be considered as coming from a point)

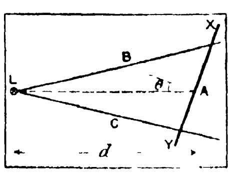

FIG. 2

The relation between luminous flux and luminous intensity being thus defined, it is possible to choose units for these two quantities such that their magnitudes are related rationally to each other It so happens that, for historical reasons, the primary photometric unit is that of luminous intensity This unit is the *international candle*, the magnitude of which was originally defined as the luminous intensity, in the horizontal direction, of a candle of specified dimensions burning at a specified rate Many years ago this form of standard was found to be unsatisfactory, and it was replaced by flame lamps of various kinds, viz, the Hefner in Germany, the pentane in this country and in America, and the Carcel lamp in France These standards have been generally abandoned, however, and the magnitude of the unit is preserved by means of specially constructed electric lamps deposited

at the various national laboratories throughout the world, viz., the Laboratoire Central d'Electricité, Paris; the National Physical Laboratory, Teddington, England; and the Bureau of Standards, Washington. The formal definition of the "candle" is as follows:

The unit of luminous intensity is the international candle, such as resulted from agreement effected between the three national standardising laboratories of France, Great Britain and the United States in 1909. The unit of luminous flux is now very simply obtained from that of luminous intensity by considering an ideal source of light which has a uniform luminous intensity of one candle in all directions. The lumen is the amount of flux emitted by such a source within a cone of unit solid angle.

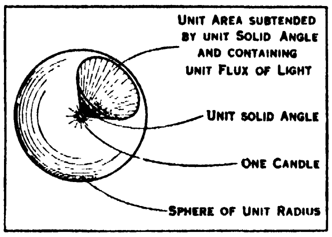

FIG. 3.—RELATION BETWEEN THE PHOTOMETRIC UNITS

The relationship is shown pictorially in fig. 3 where the ideal point source is imagined at the centre of a sphere of unit radius. Since the solid angle of any cone with its apex at the centre of such a sphere is numerically equal to the area of the spherical surface cut off by the edge of the cone, it follows that the cone shown shaded in the diagram embraces unit solid angle, so that the flux emitted by the source within this cone is 1 lumen. Since the area of the whole sphere is 4π times the square on the radius, it follows a uniform point source of 1 candle emits altogether 4π lumens. Since the total flux emitted by a source is independent of the way in which that flux is distributed, the total number of lumens given by a source is equal to the *average* value of its luminous intensity, measured in all directions in space, multiplied by the factor 4π. The luminous intensity of a source, when expressed in international candles, is termed the candle-power of the source. The average value of the candle-power measured in all directions perpendicular to the geometrical axis of the source is termed *the mean horizontal candle-power* (M.H.C.P.), while the average candle-power measured in all directions in space is termed the *mean spherical candle-power* (M.S.C.P.). It will be seen that, for any source, M.S.C.P. $= 4\pi \times$ (flux output in lumens).

Illumination: The Inverse Square and Cosine Laws.—Illumination is measured by the amount of luminous flux which reaches unit area of an illuminated surface. From this definition and the fact of the rectilinear propagation of light there follow at once the two basic laws of photometry, viz., the inverse square and the cosine laws. They will be most clearly understood by reference to fig. 2. If BLC be an elementary cone of light emitted from a source L, the area intercepted by this cone on any plane such as XY varies (i.) as the square of the distance (d) of L from the plane, and (ii.) as the secant of the angle (θ) which the normal to XY makes with the axis LA of the cone. Since the illumination produced by a given amount of flux varies inversely as the area over which that flux is distributed, it will be seen at once that the illumination of a surface varies (i.) inversely as the square of its distance from the source illuminating it (this is the inverse square law), and (ii.) directly as the cosine of the angle between the normal to the surface and the light rays (this is the cosine law).

Now let the average luminous intensity of the source L in all directions lying within the cone BLC be I candles, and let the area intercepted by this cone on the plane XY be s. Then the solid angle of the cone is equal to $(s \cos \theta)/d^2$, and the flux F emitted within the cone is $I\,(s \cos \theta)/d^2$ lumens. Since, by the definition, the illumination, E, of the surface is equal to F/S, it follows that

$$E = (I \cos \theta)/d^2$$

It will be seen that the magnitude of the unit in which E is measured must depend on the unit used for d, *i.e.*, on the unit of length. If d be expressed in feet, the unit in which E is measured is termed the *foot-candle* and, clearly, one foot-candle is the illumination produced when an area of one square foot receives one lumen of flux. Similarly, if d be expressed in metres, the unit of E is the *metre-candle* or the *lux*, and one lux is equivalent to an illumination of one lumen per square metre. It will be seen that 1 ft.-candle = 10·76 lux.

Brightness.—The last of the four fundamental photometric quantities is brightness, which is thus defined: The brightness in a given direction of a surface emitting light is the quotient of the luminous intensity measured in that direction, by the area of this surface projected on a plane perpendicular to the direction considered. The unit of brightness is the candle per unit area of surface. Thus if a flame of uniform brightness has an apparent area of one square inch when viewed in a given direction, and if the luminous intensity in that direction be 10 candles, the brightness is 10 candles per square inch. Similarly, if a surface has an area of two square metres and if its brightness when viewed normally is one candle per square metre, it has a luminous intensity of 2 candles in the direction of the normal.

The surfaces of bodies may be divided broadly into two classes, polished and diffusing, according as they reflect specularly the light they receive, after the manner of a mirror, or scatter it in all directions. A surface which scatters the light which it reflects or emits in such a way that it appears equally bright in all directions is called a "perfect diffuser." No such surface exists in perfection, but good white blotting-paper, or ground opal glass provide a fair approximation. It is sometimes convenient to use as a unit the brightness of an ideal perfect diffuser emitting or reflecting one lumen per unit area. It can readily be shown that such a surface has a brightness of $1/\pi$ candles per unit area. Thus the following relationships are derived:

1 lambert $= 1/\pi$ candle per sq.cm.
1 millilambert $= (0{\cdot}001)/\pi$ candle per sq.cm.
$= 10/\pi$ candles per sq metre.
1 foot-lambert $= 1/\pi$ candle per sq.ft.
$= 1{\cdot}076$ millilamberts.

Absorption, Reflection and Transmission.—It has been said already that bodies which are not self-luminous are visible by reason of the light which their surfaces reflect to the eye. It will be clear that, since a surface which has an illumination of one foot-candle receives one lumen per square foot, its brightness would be one foot-lambert if it were a perfect diffuser and if it reflected all the light it received. Actually, all surfaces absorb some fraction (α) of the light which reaches them and reflect or transmit the remainder. α is termed the absorption factor, while the fractions reflected and transmitted are termed respectively the reflection factor (ρ) and the transmission factor (τ). For opaque bodies it is clear that $\alpha+\rho=1$, while for all surfaces $\alpha+\rho+\tau=1$. In general the values of these three quantities depend on (a) the direction of incidence of the light on the surface, and (b) its colour. Only in the case of white or grey surfaces is the colour of the light immaterial. The brightness of a surface due to reflected light is clearly equal to $E\rho/\pi$ candles per square foot or $E\rho$ foot-lamberts, E being the illumination in foot-candles and ρ the reflection factor for the particular conditions of illumination and the direction of view considered.

Every photometric measurement depends, ultimately, upon a measurement of the illumination produced at a surface. In the case of candle-power determination, the source to be measured and a standard of known candle-power respectively illuminate two white diffusing surfaces in a photometer head which is, in essence, a device for enabling the eye to compare the brightness of these surfaces as accurately as possible. The chief conditions for accuracy are (a) that the surfaces shall be presented to the eye side by side with the finest possible dividing line, and (b) that the illumination of one or other of the surfaces may be varied according to a known law, so that the two may be adjusted to equal brightness. This is necessary because the eye cannot *measure* accurately, but can only judge of a condition of equality.

The Lummer-Brodhun Photometer Head.—The form of photometer head generally used to-day for accurate work is the Lummer-Brodhun contrast-head, the construction of which is shown in fig. 4(A). S is a matt white screen, the two sides of which are respectively illuminated by the two sources to be compared. Light from each side of S is reflected by the mirrors (or total

reflection prisms) M_1 and M_2 to the compound glass cube P. An enlarged view of P is shown in fig. 4(B), from which it will be seen that the cube really consists of two right-angled prisms. One of these, P_1, is plain, while the other, P_2 has its principal face etched or sand-blasted with the pattern shown shaded in fig. 4(C). The two prisms are pressed together so that the unetched parts of the surface of P_2 make optical contact with the surface of P_1. The

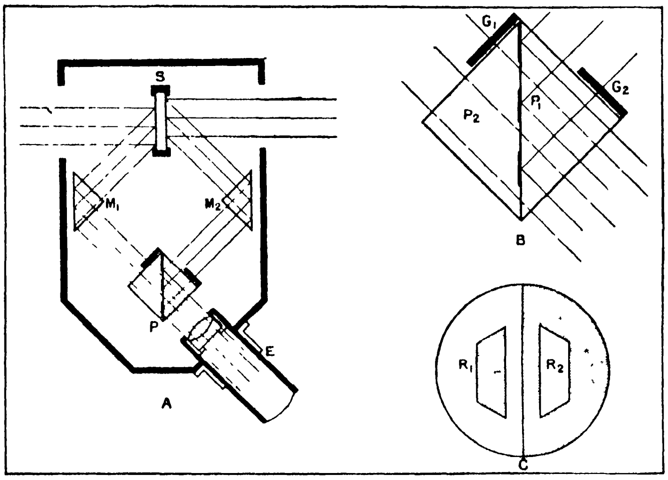

FIG 4 —THE LUMMER-BRODHUN HEAD

light from M_1, therefore, is transmitted through these portions just as if there were no discontinuity The light from M_2 is also transmitted through these portions of the face of P_1, but over the remainder, the portion shown shaded in fig 4(C), it is totally reflected and emerges side by side with the light transmitted from M_1 It will now be seen that if the eyepiece E is focussed on the interface of P, the appearance of the field is that illustrated in fig 4(C), the portion shown shaded being occupied by an out-of-focus image of the right-hand side of S, while the portion shown clear is filled by the left-hand side of S. *Assuming complete symmetry of the instrument*, it follows that when both sides of S are equally illuminated, the field of view will appear uniformly bright, and the lines of demarcation of the various parts will almost vanish if P has been skilfully constructed.

It has been found, however, that this is not the criterion of equality which the eye can appreciate with a maximum of precision, and the accuracy of its judgment can be materially improved if the criterion is changed from equality of brightness to equality of contrast This is easily arranged by placing two thin glass plates G_1 and G_2 (*see* fig 4[B]) so that they are respectively in the paths of the light beams occupying the patches R_1 and R_2 of the field of view (fig. 4[B]). Owing to reflection losses at the surfaces of these plates, their interposition causes the brightness of R_1 to be about 9% less than that of the background to R_2, while R_2 is the same amount darker than the background to R_1 It will be seen at once that, with this arrangement, if the two sides of S differ in brightness by 1%, the contrast between patch and background, instead of being 9% in both halves of the field, is 8% in one half and 10% in the other, a difference which is much easier to detect than a simple 1% difference of brightness.

The Photometer Bench.—The simplest method of varying the illumination of one of the comparison surfaces in a photometer head is to move one of the sources towards or away from the head. The law of variation of illumination is then the law of the inverse square The operation may be carried out most conveniently on some type of photometer bench This may consist of two parallel steel bars, supported at a suitable distance apart by a rigid iron framework Upon the bars run three carriages which respectively bear the light sources and the photometer head These carriages run on spool-shaped wheels so that they move easily on the bars They are provided with means for raising or lowering the sources, and for enabling them to be turned about a vertical axis Each carriage also bears a framework on which is engraved a line situated in the vertical plane which is at right angles to the axis of the carriage pillar. This framework moves over a graduated scale attached to the bench framework. By this means the distances between the centres of any two carriages may readily be found.

The most obvious method of comparing the candle-powers of two sources on the bench would be to place them one on each side of the photometer head, and adjust their positions until a balance was obtained On the assumption that equality of brightness of the two surfaces in the photometer head implied a similar equality of illumination, the candle-powers of the sources, I_1 and I_2 and their respective distances d and d' from the photometer would then be related thus:—$I_1/d^2=I_2/d'^2$ This assumption, although plausible, is never safe in practice and in all accurate photometry at the present time the substitution method is employed.

The Substitution Method.—A "comparison" lamp of constant, but not necessarily known, candle-power is placed in the carriage at one end of the bench, and this carriage is rigidly attached, by means of a rod, to the carriage holding the photometer head so that the two carriages move on the bench as one unit Thus one side of the photometer field has a constant brightness Other lamps can now be placed in turn at the other end of the bench, and the distances can be found at which the illuminations they produce at the photometer will give a balance with this constant brightness. These illuminations must, then, be equal to each other so that, if the candle-powers of the lamps be I_1, I_2, etc , and their respective distances from the photometer head at the position of balance, d_1, d_2, etc , it follows that $I_1/d_1^2=I_2/d_2^2=$ . . Thus if one of the lamps be a sub-standard of known candle-power, the candle-powers of the other lamps are found at once In all photometry it is most important that only the light directly emitted by the sources to be compared shall reach the photometer head, and stray light from external sources, or that reflected from objects in the room, must be shut off by means of suitably placed black screens

Although, owing to its convenience, the inverse square law is that most commonly used as the law governing the illumination of one of the comparison surfaces of a photometer head, there are other laws which are adopted, for special reasons in certain types of instruments The cosine law is seldom employed, but the proportionality between luminous intensity and area in the case of a surface of uniform brightness is sometimes used to provide what is, in effect a comparison source of variable candle-power The reduction of intensity of a polarized beam by the rotation of a nicol prism placed in its path (*see* LIGHT) is a favourite device in spectrophotometry (*see* p. 844), while a transparent plate of graduated transmission factor (*e g* , a small-angle wedge of neutral glass), is also useful for special purposes

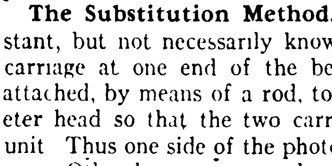

FIG 5 —PRINCIPLE OF THE SUBSTITUTION METHOD ON THE PHOTOMETER BENCH

The Sector Disc.—A very accurate method of controlling the illumination of a surface is to interrupt the light reaching it at regular and frequent intervals. It has been found that the apparent brightness of a surface intermittently illuminated bears to the actual brightness when steadily illuminated, the ratio of the time of exposure to the total time, provided the intermittency is sufficiently rapid to avoid any appearance of flicker This law is known as Talbot's law and, though it has no theoretical foundation, it has been proved experimentally that it holds with great accuracy for all ratios down to 3% or less The law may be applied by placing in the path of the light to be reduced an opaque disc having a radial slot cut in it, so that the light only reaches the photometer as the slot passes between it and the lamp If, for instance, there are three slots in the disc, each 6° in breadth, the ratio of reduction is 1/20 Such discs are exceedingly valuable as auxiliaries to other photometric apparatus, but it will be clear that, as their reduction ratio is fixed, they cannot themselves be used to produce the variation of illumination needed in a photometer For this purpose some form of disc with variable sectors is needed, and many attempts have been made to produce satisfactory apparatus of this kind.

The mechanical difficulties are, however, very great and probably the most satisfactory type of variable sector disc is that in which the disc remains stationary while the beam of light rotates. Fig. 6 shows the principle of the apparatus. The light from the lamp is reflected twice, as shown by the fine line, traverses the slot in the disc S and is again reflected so that it resumes its original direction. The reflecting surfaces may be mirrors or, preferably, the 45° surfaces of rhomboidal prisms as illustrated. In any case the four surfaces are rigidly fixed to one another in the relative positions shown, and the combination is rotated about its horizontal axis. It will be seen that the effect at the photometer surface P is precisely equivalent to that which would be produced by lowering the disc and spinning it in the usual way. As, however, the disc remains stationary, there is no difficulty whatever in making it easily adjustable by the observer, while a setting can be at once read off by having a scale on one disc and an index line on the other.

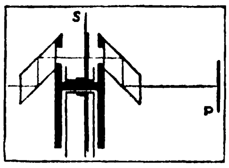

FIG 6—BRODHUN SECTOR DISC

Sub-standard Lamps.—The sub-standards used for candle-power measurement are usually tungsten filament lamps of special construction such as that shown in fig. 7. Great care has to be taken in the manufacture of these lamps so as to avoid fluctuations of candle-power due to loose contacts between the filament and its supporting hooks; the bulb, too, has to be specially selected so that there are no striations in the glass to cause slight alterations of candle-power as the lamp is rotated through a very small angle on either side of the position adopted for the standardization measurement. The candle-power of such a lamp is determined at a standardizing laboratory by comparison with the fundamental standards. The value of candle-power measured is that in the direction normal to the plane of the filament, when a given voltage is applied to the lamp contacts or when a given current is passing through the filament. These quantities have to be very accurately controlled since, in the case of a tungsten filament, a 1% change of voltage, or a 0·5% change of current, produces a change of about 3·7% in candle-power.

Flux Measurement.—Owing to the fact that most light sources are now rated in lumens instead of in candles (*see* the *British Standard Specification for Electric Lamps,* issued by the Brit. Engineering Stds. Assn), the measurement of luminous flux has now become an even more important operation in every-day photometry than the measurement of luminous intensity. The fundamental method of finding the flux output of a source is to measure its candle-power in a very large number of directions uniformly distributed in space, and thus to obtain the mean spherical candle-power which, when multiplied by 4π gives the flux in lumens (*see* p. 840). This long and tedious process may be avoided in the case of certain sources, such as a tungsten filament vacuum lamp of ordinary filament form, when the light is distributed fairly symmetrically about the axis. Such a lamp can be spun while the photometric measurements are being made, so that the figure of candle-power obtained at any given angle with the axis is, in reality, the mean value in all directions making this angle with the axis. It is therefore only necessary to make measurements in a limited number of directions, say 20, which lie in a single plane passing through the axis of the lamp.

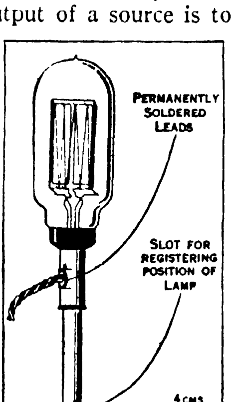

FIG 7—TUNGSTEN FILAMENT STANDARD OR SUB-STANDARD LAMP

Apparatus suitable for this purpose is shown in fig 8 which is almost self-explanatory. The lamp is mounted in a holder which can be rotated mechanically at a speed of, say, 150 revolutions per minute. The mirror system can be turned by hand about the horizontal line passing through the centre of the lamp, the photometer head and the comparison lamp. It can be shown that, if the directions in which the measurements are made be suitably chosen, the arithmetic mean of the 20 individual candle-powers gives the mean spherical candle-power with satisfactory accuracy. Such a lamp, then, may be used as a sub-standard of luminous flux, and all that is now required is a method for measuring the flux output from more irregular sources by comparison with this sub-standard.

The Sphere.—The method which is almost universally adopted to-day is based on the demonstrable fact that, if a source of light be placed inside a hollow sphere covered internally with some perfectly diffusing coating, the same amount of light is received at all parts of the sphere surface by reflection from all the other parts. The light received directly from the source naturally differs according to the candle-power distribution of the source, but the light which has been reflected once or more often from the walls of the sphere is distributed perfectly uniformly, no matter how unsymmetrical the original distribution from the source itself may be.

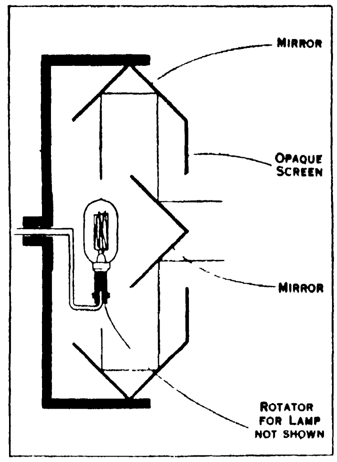

FIG 8—MEASUREMENT OF MEAN SPHERICAL CANDLE-POWER (POINT-TO-POINT METHOD)

It will now be clear that, in order to compare the total flux from two sources of light, it is only necessary to place them in turn within a sphere of the kind described, to screen a small portion of the sphere surface from direct light, and to measure the illumination of this screened area in the two cases The ratio of the illuminations will then be strictly equal to the ratio of the flux outputs of the sources. There are, of course, certain precautions which must be observed in the practical application of the method, owing to the unavoidable departures from the ideal conditions assumed in the theory The chief of these departures are (i) lack of perfect diffusion by the internal coating of the sphere, and (ii) the interference with the reflected flux brought about by the presence not only of the lamp and its accessories but also of the screen necessary to shield the measured part of the sphere surface from the direct light of the lamp

The illumination of the screened area of the sphere surface may be measured by any convenient method. It is clearly unnecessary that this measurement should be absolute, since only a ratio is involved. One method is to have a small opening in the sphere and to cover this with a window of opal glass or some other translucent material The luminous intensity of the outer surface of this window in the normal direction is then measured by means of a photometer head and comparison lamp moving on a bench attached to the sphere. Alternatively the sphere opening is left uncovered and the luminous intensity of that portion of the sphere opposite the opening is measured.

The difficulty of constructing a sphere has led to the frequent adoption of a cube as a sufficiently near approximation for work of moderate accuracy. When a cube is used, the light source should be placed in the centre, with its axis of symmetry perpendicular to the line joining it to the window, the latter being in the centre of one face of the cube. It is clear *a priori* that, if the light distributions from the sources to be compared are exactly the same, the form of the enclosure employed is immaterial. So long, therefore, as the distributions do not differ too much, a cube gives quite satisfactory results.

Illumination Photometers.—The third photometric measurement of importance is that of illumination. This is now so universal in illuminating engineering that many different types of portable photometer have been designed as illuminometers. Although these differ in design, each consists of three essential parts, viz, (i.) a test plate or standard surface placed at the spot at which the illumination is to be measured and generally, but not always, detached from the remainder of the instrument; (ii.) a surface inside the instrument, which is illuminated by a small battery lamp in such a way that its brightness can be varied at will by the observer, and (iii) some form of comparison device for

comparing the brightness of the internal surface with that of the external test plate.

The most natural form of instrument is one in which the inverse square law is used to obtain the necessary variable brightness. Such an instrument consists, generally, of a long tube blackened internally and containing a lamp in a small diaphragmed enclosure. This enclosure is attached to a rod moved by a rack and

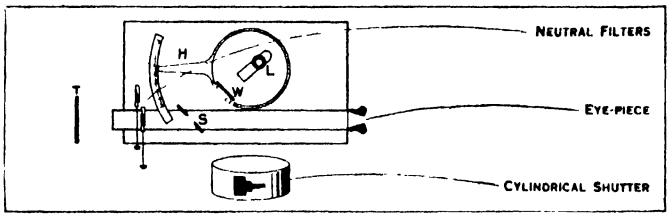

FIG. 9.—HOLOPHANE "LUMETER"

pinion so that the lamp may be brought towards or away from a piece of opal glass placed near the end of the tube. The brightness of the opal glass is compared with that of an external test surface by means of a small Lummer-Brodhun cube viewed through an eyepiece attached to the side of the tube. An inverse square scale is attached to the rod and the constant of this scale is adjusted to unity by previous calibration.

An instrument in which the inverse square law is not employed is the *Holophane lumeter,* shown in fig. 9. The lamp L is enclosed in a whitened box of shallow cylindrical form This box is provided with a window of diffusing glass W, the light from which illuminates the opaque outer parts of the comparison screen S. The eye views the test surface T through the central transparent part of S, and the two parts of the field are adjusted to equality by altering the exposed area of W. This is achieved by means of a cylindrical shutter which can be rotated about the lamp enclosure by means of the handle H. The shutter is provided with an opening of the form shown in the figure It will be clear that if W is uniformly bright, the scale of the instrument will consist of two parts, one corresponding to each of the breadths of opening, the scale being even within each part.

In most illumination photometers the scale of the instrument may be extended by the provision of neutral glass screens with transmission factors of one-tenth If these are inserted between the test surface and the eye, the scale is extended upwards, the instrument reading having to be multiplied by 10 or 100 according as one or both of these screens is inserted. If the screens are inserted between the internal lamp and the comparison surface, the instrument reading must be divided by the appropriate factor The lamp is supplied from some form of portable battery, preferably, an "accumulator." A rheostat and a voltmeter or ammeter are provided for adjusting the current through the lamp to the value at which the instrument was calibrated This adjustment has to be made with the greatest possible care since, owing to the characteristics of the small battery lamps which have to be used, an error of 1% in the current setting may result in an error of as much as 10% in the readings

The calibration of every portable photometer should be checked at frequent intervals This may be done by setting up the test surface at the zero point of a photometer bench and placing a sub-standard of known candle-power at convenient distances from it so as to give even values of illumination at the surface The test surface should approximate as closely as possible to a perfect diffuser. Ground opal glass or sandblasted opaque white celluloid are frequently used.

Measurement of Brightness and Reflection Factor.—Any illumination photometer which employs a detached test surface may be used for measuring the brightness of a surface, or its reflection factor if it is not self-luminous. This will be made clear by means of an example. When the instrument is set to a reading of, say, E foot-candles, a balance is obtained when the illumination of the test surface has this value. If, now, the reflection factor of this surface be ρ, its brightness under these conditions is $E\rho/\pi$ candles per square foot, or $E\rho$ foot-lamberts. Hence if, when the photometer is sighted on any other surface, a balance is obtained at the mark E on the instrument scale, the brightness of this surface must be $E\rho/\pi$ candles per square foot. Thus to convert the scale of illumination on the instrument to a scale of brightness it is only necessary to multiply by the constant factor ρ/π. Similarly, it is clear that, if two surfaces be equally illuminated, their brightnesses are proportional to their reflection factors. If, therefore, a surface of reflection factor ρ' be substituted for the test surface of an illumination photometer, the reading obtained will bear to the actual illumination the ratio ρ'/ρ where ρ is the reflection factor of the test surface.

It will be seen that for the measurement of either brightness or reflection factor a knowledge of ρ, the reflection factor of the photometer test surface, is necessary. This may be obtained by setting up the surface at one end of a photometer bench, illuminating it with a lamp of known high candle-power at a known distance, and measuring the candle-power I of the surface by means of a photometer head and comparison lamp in the ordinary way If E be the illumination of the test surface in foot-candles and s its area in square feet, $I=\rho Es/\pi$, so that ρ is found.

Heterochromatic Photometry.—No mention has so far been made of what is, perhaps, the greatest difficulty in all photometric measurement, viz., a difference of colour between the lights to be compared. The modern electric lamp gives light which is much "whiter," *i.e*, contains a larger proportion of blue, than that given by the carbon filament lamp.

Since the primary photometric standards are carbon filament electric lamps, operating at an efficiency of about 4·8 watts per candle, it is clear that, at some stage or another in the measurement of modern light sources, large colour differences have to be bridged with as little loss of accuracy as possible. There are three generally recognized methods of doing this, viz , (i.) the cascade method, (ii) the flicker method, and (iii) the colour filter method based on spectrophotometry Each of these methods will be described briefly in turn, but mention must first be made of a peculiarity of the eye which complicates the problem The curve shown in fig 1 gives the relative response of the eye to equal amounts of energy at different parts of the spectrum This curve, however, only applies when the brightness of the field of view is 0·15 candle per square foot or over Below this limit the curve shifts gradually to the left so that at low brightnesses the maximum is at a wave-length of about 505 $m\mu$. It follows that, if two fields are illuminated, one by red and one by green light, it may quite well happen that, when the brightness of both fields is high, the red may appear the brighter of the two, while, if both be reduced in brightness in the same ratio, the balance may appear to shift over so that the green may appear brighter than the red This effect is known as the Purkinje effect, and it has to be guarded against by ensuring that the brightness of the field of view is well in excess of the limiting value mentioned above

In the cascade method of heterochromatic photometry, the colour difference between the two lights to be compared is divided into a number of small steps by the interposition of other sources giving lights of intermediate colour. The method, however, is not entirely satisfactory since, clearly, an observer who weights the "whiter" light, will do so throughout the series of comparisons, and so his errors at each step will add up in the final result

The Flicker Photometer.—The flicker method depends on the fact that, when the field of view is illuminated alternately by lights which differ in colour and in intensity, flicker due to colour difference vanishes at a lower speed than flicker due to brightness difference A photometer head constructed on the flicker principle is designed so that the two surfaces which make up the comparison field are presented to the eye, not side by side, but one after the other in rapid alternation At low speeds the field is observed to flicker whatever the position of the photometer head, but as the speed is raised the flicker gradually decreases until finally it can be made to disappear at one position of the head only. If the speed be maintained at this critical value, a slight movement of the head from the position of balance causes a flicker to appear. The critical speed depends on the colour difference between the lights, being naturally higher the larger the difference. Any increase in speed beyond that just necessary to

remove flicker at the point of balance results in a decrease of sensitivity. It is therefore a first essential of any flicker photometer that it should be provided with an easy and rapid speed adjustment.

It is by no means self-evident that the results obtained by this method will agree with those obtained either by the cascade method or by a direct comparison involving the whole colour

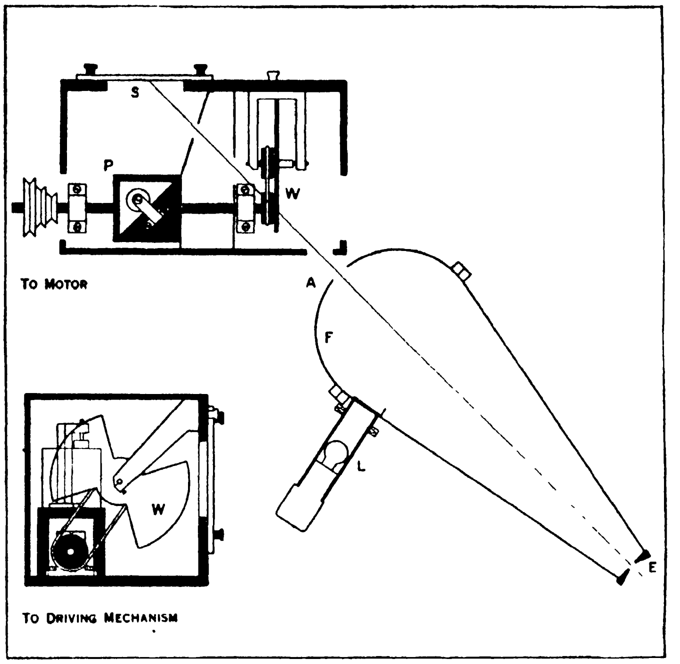

FIG. 10 —FLICKER PHOTOMETER

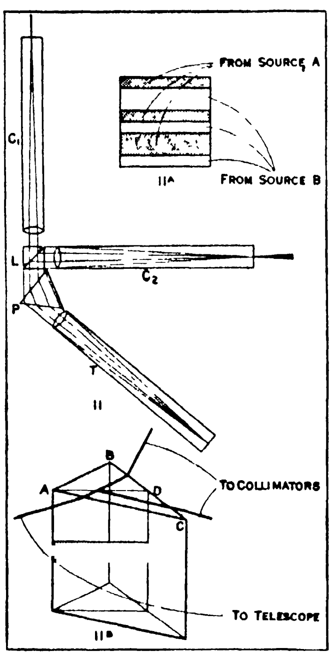
difference and carried out by a large number of observers using, say, the Lummer-Brodhun photometer Much experimental work has been done on this subject and it has been found that the two methods are in agreement when the following conditions are complied with in the flicker measurement: (*a*) a flicker field of about 2° diameter, and (*b*) a field brightness of about 8 candles per sq. metre. Since a 2° field is very small, and is most tiring for continuous work, the flicker field should be surrounded with a steady extended field of the same or slightly lower brightness

Many different types of flicker photometer have been developed. Of the more accurate, the one shown in fig. 10 is, perhaps, the simplest in principle, and will serve to illustrate the method S is a white surface illuminated, by way of the total reflection prism P, by the light from one of the sources to be compared W is a sector disc, which can be rotated at any desired speed about a horizontal axis. Its surface is white and is illuminated by the other source of light so that, when viewed by the eye at E, the field of view seen through the small aperture A is alternately occupied by W and by S. A is of such a size as to subtend an angle of 2° at E. It is cut with a sharp (back-bevelled) edge in a concave surface F, which is evenly illuminated by the small lamp L. L is adjusted to give F a brightness of about 8 candles per square metre, and the distances of the sources to be compared are then arranged so that the brightness of the field at A has approximately the same value The test lamp and photometer are then fixed and measurements are made by moving the comparison lamp, the speed of rotation of W being reduced until flicker can be made almost to disappear. Settings of the comparison lamp are then made to the point of minimum flicker. It will be noticed that the criterion of equality used in this instrument is not disappearance of flicker but minimum flicker, as it has been found that in practice this gives a rather more sensitive test of the balance point.

The Spectrophotometer.—The third method for overcoming a colour difference in photometry is to place between the photometer head and one of the sources of light a sheet of some transparent medium of such a colour that it produces a colour-match with the light from the other source. If, then, the transmission factor of this medium be known for the light given by the source with which it is used, the problem is solved The only method of obtaining this information is to determine (*a*) the spectral energy distribution of the source, and (*b*) the transmission factor of the medium at each wave-length. The overall transmission factor τ is then given by $\int \tau_\lambda K_\lambda E_\lambda / \int K_\lambda E_\lambda$, where E_λ is the energy emitted by the source in a given wave-length interval at wavelength λ and K_λ is the corresponding luminosity factor.

The instrument used for determining both the above sets of data is called a *spectrophotometer,* since it is essentially a device for enabling the intensities of two lights to be compared at any given part of the spectrum instead of as a whole Every spectrophotometer, therefore, consists of two parts, (i) a spectrometer (*see* SPECTROSCOPY) for enabling any given wave-length interval of the lights to be isolated, and (ii) some device for causing the portions of the lights so selected to illuminate the two parts of a comparison field, and a means for altering the brightness of one part of this field.

The principle will be made clearer by means of an example Fig. 11 shows diagrammatically the Lummer-Brodhun instrument which consists of an ordinary spectrometer with the addition of a second collimator C_2 and a Lummer-Brodhun cube The latter is constructed similarly to the cube used in the ordinary photometer head (*see* p. 841) but the form of the field is that shown in fig 11. The two sources to be compared respectively illuminate the slits of C_1 and C_2 which may be covered with diffusing glass For the adjustment to a photometric balance various devices may be used, *e g* , a variable slit in one collimator, alteration of the distance of one source from its slit, a sector disc or neutral wedge in one beam, or a pair of nicol prisms (one capable of rotation through a measureable angle) mounted in one of the collimators The last-mentioned device is used in the Brace-Lemon instrument which is a modification of the Lummer-Brodhun spectrophotometer, the dispersing prism being used also to form the comparison field This prism is shown in fig 11 As in ordinary photometry the substitution method is generally employed The source used as a standard of spectral distribution is frequently a tungsten filament



FIGS 11, 11A —LUMMER-BRODHUN SPECTROPHOTOMETER
FIG. 11B —BRACE-LEMON PRISM

vacuum lamp, since the spectral distribution of this type of lamp is very closely determined by its efficiency Alternatively any suitable lamp may be used, the spectral distribution of which has been determined at a standardizing laboratory.

One of the most important uses of spectrophotometry is to determine at each part of the spectrum the transmission factor of a coloured medium, a chemical solution, etc This may be done quite readily by first obtaining a balance for two sources of light at any one wave-length, and then inserting the coloured medium between one of these sources and the photometer. The amount by which the intensity of the other beam has to be altered to restore the balance enables the transmission factor of the medium at the particular part of the spectrum isolated to be reduced

Physical Photometers.—Many attempts have been made at various times to develop some physical instrument which can be used instead of the eye for making photometric measurements The instruments proposed may be divided, roughly, into three classes. The first of these includes the vast number of chemical photometers in which the illumination is measured by the rate of change it produces in the constitution of some chemical mixture. This form of photometer survives in the photographic

method used in some branches of spectrophotometry and in stellar photometry (*see* below). The chief disadvantage of the method is, as in all physical photometry, that the response of the sensitive substance to equal rates of energy reception in the form of light of different wave-lengths is quite different from that of the eye. In other words, the luminosity curve of the physical photometer is not even approximately the same as the curve of fig. 1. This, clearly, is of no importance in spectrophotometry where the comparison is made separately at each part of the spectrum. The principal difficulty associated with photographic spectrophotometry is the lack of proportionality between exposure (illumination × time) and blackening Schwartzchild's law that, for equal photographic densities, Et^p is a constant (p has a value between 0 75 and 1 depending on the plate) holds for short ranges of E and t.

The second class of physical photometer is that depending on the change (usually increase) of electrical conductivity of the element selenium when illuminated A sensitive selenium bridge (frequently termed *selenium cell*) may be made by winding four strands of fine nickel or platinum wire round a sheet of some good insulator which has been covered on one side with a thin layer of purified amorphous selenium. If two alternate strands of wire are then removed, the remaining strands are separated by a long strip of selenium of the same breadth as the diameter of the wire By heating the bridge to a temperature of about 180° C for five minutes or longer the selenium is changed to the metallic form and the conductivity of the path between the wire then varies with the illumination of the bridge. Many other forms of cell have been developed for various purposes. This type of physical photometer is not only subject to the disadvantage that its luminosity curve is different from that of the eye and is, moreover, not the same at all intensities of illumination, but it has the additional defect of a lag both in response to stimulation and in recovery after the illumination has been cut off.

Photoelectric Photometry.—The most promising form of physical photometer is the photoelectric cell described elsewhere (*see* PHOTOELECTRICITY) Although the luminosity curve of any such cell is very markedly different from that of the eye and is, moreover, slightly different even for two cells made similarly with the same photoelectric metal, it has been found that a combination of a potassium cell with a suitable yellow filter (Wratten K3) gives a curve which approximates to that of fig. 1 sufficiently closely for a device of this nature to be used as a physical photometer.

Various methods may be employed for carrying out a measurement with such a cell-filter combination The simplest is to have the combination illuminated in succession by the sub-standard and the lamps to be measured, and to balance the photoelectric current in each case by that from a simple photoelectric cell illuminated by a comparison lamp mounted on a bench (*see* fig. 12). The two cells, with their batteries, are connected in a Wheatstone bridge arrangement with a sensitive electrometer, and the distance of the comparison lamp from the cell it illuminates can be altered until the electrometer ceases to show a deflection The illumination of the cell-filter combination is then proportional to I/d^2 provided both cells follow the same law connecting photoelectric current and illumination. It is unsafe to assume that this is the case over a very extended range of illumination, so that the sub-standard and the test lamps must be arranged to give illuminations of the same order at the cell-filter combination In the case of a measurement of luminous intensity this can be done quite easily, but when the cell is being used in combination with a sphere or cube for the measurement of luminous flux, some auxiliary means must be adopted for adjusting the value of the illumination. A sector disc may be used since Talbot's law is rigorously obeyed by a photoelectric cell, its response to light being practically instantaneous. For increasing the sensitivity of a photoelectric cell, a three-electrode valve is often employed. Such a combination will, in conjunction with a suitable galvanometer and chronograph, enable records of a varying illumination (*e.g.*, daylight) to be obtained

CELESTIAL

The earliest records we possess as to the positions of the stars have always been accompanied by estimations of their relative brightness; the stars being arranged in "magnitudes" according to their apparent luminosities Thus, in the catalogue of stars published by Ptolemy (*c.* A.D. 150) but which had probably been formed 300 years previously by Hipparchus, the stars visible to the unaided eye were divided into six classes or magnitudes, the brightest stars being designated "first magnitude stars" and those just visible to the naked eye forming the "sixth magnitude." Each class was further sub-divided into three sub-groups. This process of arranging the stars by eye estimates (with the unaided eye at first and subsequently with the aid of telescopes) was further developed by Flamsteed and the Herschels, and culminated in the work of Argelander, Schonfeld and Kruger, who published three catalogues (1859–62) of celestial co-ordinates and magnitudes known as the *Bonn Durchmusterung*. This catalogue included the enormous number of 324,188 stars. An additional volume containing 133,659 stars south of the equator was published in 1886 and the work was further extended in the southern hemisphere by B. A. Gould, J M Thorne and others In the *Bonn Durchmusterung*, or "B D ," each magnitude is sub-divided into ten divisions, a decimal notation being used.

So far no attempt was made to define the quantitative relationship between different magnitudes. In modern times a definition due to Pogson has arisen, and we define a difference of one magnitude between two stars as meaning that the light that reaches us from the first star is k times the light which reaches us from the second. The constant k is chosen so as to make a difference of five magnitudes correspond to a light ratio of 100 and this means that we must have $\log_{10}k = 0\ 4$. We cannot observe all the radiation emitted by a star. If the instrument used for registering the light be the human eye, it will not respond to radiation either in the extreme ultra-violet end of the spectrum or in the extreme infra red. Now if two stars are of different colours, the proportion of the whole radiation represented by the light which affects the eye will be different for the two stars, and the adoption of the above definition as it stands would lead to difficulties We can retain it, however, for stars of the same colour and then, as far as visual magnitudes are concerned, we define two stars of different colour as being of the same visual magnitude when they appear equally bright to the eye With the introduction of photographic methods, a photographic scale has arisen defined in the same way; two stars being of equal photographic magnitude when they produce equal photographic effects. Reference will be made below to certain difficulties arising out of these definitions With regard to the zeros or starting points of these visual and photographic scales, the zero of the measured scale of visual magnitudes has been fixed so that the magnitudes agree approximately with those in the "B D " for the mean of stars down to the sixth magnitude, whilst the zero of the photographic scale is defined so that for the white stars (of spectral type Ao) of the sixth magnitude (between visual magnitudes 5·5 and 6 5) the visual and photographic magnitudes are equal.

The actual methods of procedure, both visual and photographic, will be given in outline later in this article In recent years an enormous stimulus has been given to stellar photometry by the realization that it can lead us to good estimates of the distances of remote objects It was pointed out by Hertzsprung (*see* STAR), that the period of certain variable stars was related to their absolute magnitude, *i.e.*, to the magnitude that they would appear to have when viewed by an observer at a certain standard distance By observing the period the absolute magnitude can be deduced, and then, provided the apparent magnitude has been measured, the distance of the star can be inferred The discovery and elabo-

ration of methods such as these has led to the extension of the photometric scale down to the 20th magnitude. The scale of magnitudes defined numerically can of course be extended on the negative side, and, in point of fact, the visual magnitude of Sirius is −1·4 whilst that of the sun is −26·7.

MODERN WORK ON VISUAL MAGNITUDES

The bulk of observational work on visual magnitudes has been carried out at Harvard, and at the Harvard station in the southern hemisphere (but a considerable amount has been accomplished at Potsdam), and the standard catalogue of visual magnitudes for the brighter stars is the "Revised Harvard Photometry" (*Harvard Annals*, vol 50). This catalogue contains the computed magnitudes of 9,110 stars, of magnitude 6·5 and brighter, distributed over the whole sky A further catalogue (*Harvard Annals*, vol. 54) gives the magnitudes of 36,682 stars fainter than 6·5. The instrument used at Harvard was the meridian photometer designed by the late Prof. Pickering The principle underlying the instrument is the presentation of two stars in the field of view, the light from one being varied by a Nicol prism until the two stars appear of equal brightness. The ratio in which the incident light has been varied is read off from the angle through which the Nicol has been rotated, and the difference of magnitudes of the two stars thus obtained The stars were all compared with a standard star, which was the Pole star in the case of the brighter stars and λ Ursae Minoris for the fainter ones.

The photometer (*Harvard Annals*, vols. 14 and 23) consists of two telescopes placed side by side pointing due east, the light from the stars on the meridian being reflected into them by two mirrors inclined at an angle of 45° to this direction If there were a star exactly at the Pole, one of these mirrors would be absolutely fixed and would constantly reflect the light of this star down the axis of its telescope; in practice a slight motion can be given to the mirror so as to keep in view the polar star selected as the standard of comparison. The second mirror (which projects a little beyond the first so as to obtain an unobstructed view of the meridian) can be rotated round the axis of the telescope by means of a toothed-wheel gearing, and can thus be made to reflect any star on the meridian down the second telescope; it is also provided with a small motion in the perpendicular direction, so as to command a degree or two on each side of the meridian. Near the common eyepiece of the telescopes there is a double image prism which separates the light received from each into two pencils; the pencil of ordinary rays from one object-glass is made to coincide with that of extraordinary rays from the other, and the two remaining pencils are excluded by a stop The two coincident pencils then pass through a Nicol prism to the eye of the observer, who by rotating the prism round its axis can equalize them at a definite reading depending on their relative intensities. This reading gives in fact the difference of magnitude between the two stars selected for comparison. It may be remarked that the position of the double image prism is important. It should be just *within*, not *at*, the common focus; this position prevents any noticeable colour in the images, and gives the ordinary and extraordinary pencils a sufficient separation at the eye-stop to permit the entire exclusion of one without the loss of any part of the other. If the prism were exactly at the focus, and any part of the superfluous images were admitted, the resulting secondary images would coincide with the others and thus lead to errors in observing As it is, owing to the construction of the instrument, if the secondary images appeared at all they would do so only as additional stars, near those under observation and too faint to produce any inconvenience.

Each observation consists of four comparisons; after the first two the observer reverses the position of the star images in the field, and also reverses the double-image prism. The former precaution is necessary to eliminate a curious error depending on the relative position of the images, which may amount to several tenths of a magnitude. Errors of this kind affect *all* estimates of the relative brightness of two stars in the same field, as has been repeatedly shown; a striking instance is given by A. W. Roberts of Lovedale, South Africa (*Mon Not R A S*, 1897), who found that his eye-estimations of the brightness of variable stars required a correction depending on the position-angle of the comparison star and ranging over nearly two magnitudes. In the Harvard work on the brighter stars, the magnitude of the pole star was provisionally assumed to be 2·0 at the pole. Each observation had to be corrected for the effect of atmospheric absorption, the coefficient for which was obtained from observations of circum-polars at upper and lower culminations. The provisional magnitudes thus obtained were finally corrected by a constant chosen so as to make the mean magnitude of the circum-polars equal to the mean magnitude of the same stars as given in the "B D."

Other types of photometer are Zollner's (*Photometrische Untersuchungen*, h. 81), in which an artificial star is taken as the standard of comparison, and Pritchard's, in which the images of stars are viewed through a wedge and the wedge-reading at which the star is extinguished noted.

The comparison of different catalogues of visual magnitudes reveals small systematic differences which arise out of the difficulties of estimating when two stars of different colour are equal in apparent intensity The observation is complicated by what is known as the "Purkinje phenomenon" If a blue source of light and a red source appear equally bright to the eye, and if the intensity of each be diminished in the same ratio, they will no longer seem equally bright, the blue appearing the brighter From this cause, magnitudes observed with meridian photometers of different aperture will differ slightly It becomes obvious that visual magnitudes ought to be referred to some standard instrument, and possibly to some standard observer, and it is difficulties such as these which are at the present time leading to the replacement of visual magnitudes by what are known as photo-visual magnitudes.

PHOTOGRAPHIC PHOTOMETRY

Here, we are dealing with a problem which differs considerably in detail from the visual procedure. We can no longer vary the light of a star by some device such as a Nicol prism until it is equal in brightness to a standard But on a plate which has been exposed to a field of stars we can at any rate arrange the stars in order of brightness by measuring the diameters of the images, or by estimating their degrees of blackness, and we are then faced with the task of finding a means of relating our measures of blackness or of diameter to the true photometric scale defined as above

Two principal methods have been employed, the in-focus method and the out-of-focus method. In the in-focus method a field of stars is photographed twice on the same plate, the intensity of the light being reduced in some known ratio for the second exposure. This can be effected by stopping down the aperture of the telescope by a given amount. The plate is placed in the usual position, that is, in the focal plane of the object glass or mirror For each star we then have two images on the plate whose difference in magnitude is known Now suppose we measure the photographic effect of each image in some way and denote the measure by D A simple measure of photographic effect is the diameter of the image, in which case D is the measured diameter Suppose D_1 and D_2 be the measures on the two images of the same star The difference of magnitude between these two images depends only on the ratio in which the aperture has been stopped down and is consequently known. We thus get the magnitude difference corresponding to the difference of the measures D_1 and D_2. In other words, we are relating the scale of our measures of photographic effect to the magnitude scale, and we thus have a means of converting the measures into magnitudes and of obtaining the relative magnitudes of all the stars on the plate.

The principle of the method is as follows. Select a sequence of stars on the plate such that the diameter (or any other measure of photographic effect that may be adopted) of the fainter image of any member of the sequence is equal to the diameter of the brighter image of the next succeeding member. We then have a sequence of stars each member of which differs in magnitude from the following member by a known amount. In other words,

the magnitudes of the stars of the sequence are known, but with an arbitrary zero point. If then, the measured diameters of these stars be plotted against their magnitudes obtained in this way, a curve would be obtained from which the magnitude of any star on the plate can be read off from its measured diameter. In actual practice a mathematical process is used instead of a graphical one. Furthermore, the equality between the fainter and brighter images of two consecutive members of the sequence will not be exact and this must be allowed for.

So far this method only gives a means of determining the relative magnitudes of stars in the same region of the sky and which can therefore be photographed on the same plate, but if we expose every plate a second time on some standard area, the time of exposure being the same, we can determine the magnitudes relatively to some star or stars in the standard area (which may conveniently be the area of the Polar sequence); and it only remains to define the zero. This has been fixed, as already explained, so as to make the photographic magnitudes of the white stars of the 6th magnitude agree with their visual magnitudes on the Harvard scale. Instead of using a stop to reduce the light in a given ratio for a second exposure, it is preferable to use a coarse wire diffraction grating placed over the aperture of the telescope. Each image is then flanked by fainter lateral images differing in magnitude from the main image by a known amount depending on the thickness and spacing of the wires. The subsequent procedure is unchanged, but only one exposure is necessary. In order to give some idea of the appearance of such gratings, it may be mentioned that one of the gratings used at Greenwich in conjunction with the 26-inch refractor consisted of wires 0·69 mm. in diameter and spaced at intervals of 5 mm. (*Monthly Notices R.A.S.*, 1913).

At Harvard the out-of-focus method has been used. In this case a series of exposures are made and for each exposure the plate is placed at a certain distance from the focus. Each star is now represented by a blackened patch on the plate, instead of by the usual image, and the density of the silver deposited in each patch is measured by comparison with a graduated wedge. In the case of the different exposures to the same star at different distances from the focus, the relative quantities of light falling upon unit area of the plate are determined from straightforward geometry, and the relation between the measured densities and the magnitude scale thus determined (*Harvard Annals,* vol. 59). It may be remarked that the out-of-focus method lends itself readily to the determination of the magnitudes of planets. For the purpose of determining the magnitudes of the sun and moon, a pin-hole camera was used by the Harvard observers, and they obtained −25·83 m. for the photographic magnitude of the sun and −11·20 m. for that of the full moon (*Harvard Annals,* vol. 59).

In recent years a great deal of care has been lavished upon the determination of the magnitudes of a sequence of stars extending down to the 20th magnitude and situated at the North Pole of the sky. This having been done the magnitudes of stars in any other part of the northern sky can be obtained by photographing the field and the pole on the same plate and with the same exposure. In order to eliminate atmospheric absorption the exposures should be made at the same altitude. Measures (say of diameter) can then be made of all the stars in each field, and the measures calibrated from the determined magnitudes of the Polar sequence. Several secondary sequences have been determined in this way in various parts of the sky and the work is being pushed into the southern hemisphere.

Colour-indices and Standardization.—The visual and photographic magnitudes are not necessarily the same. A red star, for example, may affect the eye strongly, but its effect on an ordinary photographic plate, which is chiefly sensitive to blue light, may be small. The difference between the photographic and visual magnitudes of a star (which in extreme cases may amount to 1½ magnitude), reckoned in the sense photographic minus visual, is called its colour-index. However, a little consideration will show that photographic magnitudes determined with different instruments (or different plates) will differ from each other. For example, in a refractor a large portion of the ultra-violet light is absorbed by the lens, and in a reflector this light is let through to a much greater extent. Clearly the photographic magnitudes as determined with these types of instruments will be different. It is necessary to adopt some standard, and the International Astronomical Union, in defining the magnitudes of the standard polar sequence, has adopted the scale of the 60-inch reflector at Mt. Wilson. The magnitudes m of stars in any catalogue can be connected with the standard magnitudes m', which are referred to the scale of the 60-inch by an equation of the form

$$m = m' + a + bC$$

where C is the colour index and a and b are constants.

At Mt. Wilson Dr. Seares has devised a method of measuring colour-index directly. He photographs stars on colour-sensitive plates through blue and yellow filters and he defines the "exposure ratio" as the logarithmic ratio of the exposure times which produce blue and yellow images of the same size. The results have to be calibrated by comparison with colour-indices, but, this having been done, the method has the advantage of determining the colour directly instead of by differencing two separate magnitude determinations. A further direct measure of colour is provided by the "effective photographic wave-length" of a star. This may be defined as the wave-length of the light from the star which produces the maximum effect on a photographic plate. It is greater for the red stars than for the blue, and may be determined by placing a coarse diffraction grating over the aperture and then measuring the distance on the plate between the central image of a star and the most intense part of the lateral image produced by diffraction (*Monthly Notices R.A.S.*, 82, 1921). Effective wave-lengths having been determined, they can be calibrated by comparison with colour-indices.

Photovisual Magnitudes.—Just as different photographic determinations differ, so will visual observers using different instruments obtain different results. There is also the complication arising from the Purkinje effect. For this reason attempts have been made of recent years to replace visual determinations by photographic ones made on colour-sensitive plates through yellow screens. The resulting magnitudes are called photovisual magnitudes. They are roughly the same as the visual ones, at any rate for the brighter stars, and lend themselves readily to standardization. Photovisual magnitudes have been determined at Mt. Wilson for the stars of the polar sequence. When compared with the Harvard visual results they show differences depending on colour, which become more pronounced for the fainter stars, and may amount to as much as three-tenths of a magnitude for red stars of the 12th magnitude.

Spectro-photometry.—It has been long recognized that the colour-index of a star bears a relation to its surface temperature—the bluest stars being the hottest—and it is immediately suggested that the temperatures of the stars might be calculated from colour-index data. This would be possible if the visual and photographic magnitudes referred to definite wave-lengths, instead, as is actually the case, of being results integrated over a certain range of spectrum. Consequently the satisfactory determination of what are known as effective temperatures can only be obtained by spreading out the light into spectra and confining the photometric measurements to certain definite wave-lengths.

The effective temperature of a star may be defined, for the present purpose, as the temperature of a full radiator or "black body" for which the distribution of the energy in the spectrum most closely fits the observed distribution in the stellar spectrum. It is assumed that if, as is usual, measurements are confined to those spectral regions which are free from absorption lines, the stellar distribution of energy is very nearly that of a black body; and this is probably the case. The principle of the method may be stated thus. If for two stars the ratio of the light reaching us be measured for two separate wave-lengths, and if the effective temperature of one of them, which is thus regarded as a standard star, be known, then the effective temperature of the other can be calculated. The problem is thus reduced to determining this ratio for two separate wave-lengths, or, which comes to the same thing, the difference of magnitude for the two wave-lengths in

question. Actually it is not necessary to determine each of these differences, the *difference* of the differences is all that is required. The object of spectro-photometric measurement is thus to determine what is in reality a colour-index, determined with respect to two definite wave-lengths, say in the blue and the red regions of the spectrum. Then, if the effective temperature of the standard star be known, the effective temperatures of any others can be derived The standard star need not be an actual star, but an artificial source of light whose effective temperature can be determined in the laboratory

It is on these lines that research has been pursued at Potsdam, Edinburgh, Victoria, Greenwich and at other observatories The work is still in its infancy and it is impossible to go into details here. With the exception of Potsdam, photographic methods are employed, and one method is to measure the densities of the silver deposited in the spectra with some form of microphotometer. It then remains to relate the measures of density to the absolute photometric scale just as in the case of ordinary photometry. A graded series of images in light of the requisite wave-lengths must be imposed on the plate and the measures of density thus calibrated. In the case of the visual work carried out at Potsdam, the spectra were compared at each wave-length with a Nicol prism photometer in a manner analogous to the Harvard visual photometry. The results that have been so far obtained are not altogether accordant, and are subject to revision. The available observational data have been summarized by A. Brill (*Astronomische Nachrichten* 5,539, 1928), who has given a table connecting spectral types and effective temperatures. According to this table, the mean effective temperatures of stars of type Bo is 20,800° Absolute. For type Ao the effective temperature is 11,300° A and for type Go (the solar type) it is 6,050° A for the "giants" and 6,240° A for the "dwarfs." For the very red stars of type Mo Brill gives 3,200° A and 3,420° A for the giants and dwarfs, respectively.

A very recent development is the determination, by photometric methods, of the integrated intensities of absorption lines, *i e*, the ratio of the total amount of light absorbed in a line to the amount of light per unit of wave-length in the neighbouring continuous spectrum. Some very promising work on these lines has been carried out at Harvard and it is probable that it will be developed rapidly in the immediate future. (W. M. H. G.)

PHOTON: *see* COMPTON EFFECT.

PHOTOPERIODISM, the term employed to designate the response of organisms to length of day, with special reference to plants. Its possible application to animal life has not yet been adequately investigated, though there is some evidence of its connection with bird migration So far as known at present, sunlight may affect plant growth in three ways, in virtue of its composition, including visible and invisible radiation, in virtue of its intensity and its daily durations.

It has been found that, for the sake of convenience, plants may be considered to fall into three great groups, depending upon the initiation of sexual reproductive expression and flowering in response to different day-lengths. In one group, termed the short-day plants, day-lengths of 12 hours or less are most favourable to the initiation of sexual reproduction In a second group, the long-day plants, lengths of day in excess of 12 hours, amounting in some instances to continuous illumination are most favourable for reproduction and flowering A third group includes plants which attain sexual expression independently of any particular length of day. Such plants have been called indeterminate types, because they show no distinctive flowering response to either long or short days.

By the use of appropriate dark, ventilated chambers, or houses in which plants may be placed, cutting off the early morning and later afternoon light of the long days of summer, it has been found practical to study the behaviour of plants as affected by daylight exposures much shorter than the normal. During the short days of winter, greenhouses suitably heated have been used, with electric illumination afforded the plants at sunset to increase the daily illumination periods to the desired degree. The behaviour of responsive plants has been consistent under the two conditions, according as they are normally long-day, short-day, or indeterminate types of plants. *Poinsettia* is an example of a typical short-day plant, because the initiation of reproduction does not take place until the seasonal day-length has fallen below 12 hours. Buckwheat is an indeterminate type of plant, and Oswego tea or bee balm (*Monarda didyma*), a garden ornamental, demands the long midsummer days for flowering.

The distinctive response of the different species of plants appears to have much to do with their normal ranges in many instances, at least it is one of the factors in the environmental complex, which must also be considered in any study of natural distribution. Likewise the geographical limits of some of our cultivated crops probably depend to a greater or less extent upon this factor. Biloxi soy beans, for instance, a crop fruiting successfully in the Gulf States, cannot be grown for seed in the Washington region (latitude 39°), because they do not flower until the September length of day is reached. As a result, unfavourable temperatures with frost ensue and kill the plants while the pods are still immature.

As originally defined, photoperiodism refers to the normal 24-hour period of time, a constant condition which holds everywhere on the earth except at the poles. Breaking the normal daily duration of light during the long days of summer with a period of darkness of one to several hours in the middle of the day does not appear to produce any fundamental effect upon the normal reproductive development of typical long- or short-day plants.

In addition to its effects upon sexual reproduction day-length is known to modify composition, growth and development of plants in various ways, including tuberization, branching habit, root and rhizome development, stature, dormancy, leaf fall, senescence, rejuvenescence and cleistogamy.

In any analysis of plant behaviour, either in the field or in the laboratory, the factor of photoperiodism must be considered as operative in the environmental-complex. Just as plants are known to have their specific requirements with respect to temperature, moisture, light-intensity, etc., it is known that they have definite length-of-day requirement for promoting the different phases of vegetative expression of flowering and fruiting The character and extent of these expressions, the seasonal behaviour, stature, longevity, etc, may be more a matter of response to length of day than anything else. This principle has probably been unconsciously applied in the agricultural operations of man with his various economic and ornamental plants, just as the requirements of temperature, light-intensity, soil, moisture, etc., have been met. Definite recognition of the principle will unquestionably aid greatly in a more intelligent interpretation of plant behaviour, and prove a factor of no small importance in the successful introduction of plants from one region into another. The phenomena of photoperiodism were brought to the attention of the scientific world in 1920 by workers in the U S. Department of Agriculture

See K. F. Kellerman, *Quarterly Review of Biology* (1926).

PHOTOSPHERE of the sun, the layer from which most of the sun's light is emitted which reaches us directly; *i.e.,* without absorption and re-emission The sun is a globe of gas with no sharply defined surface, and we look down into it through absorbing layers of very low density; the photosphere may be regarded as the layer which is the limit to which we can see into the interior. (*See* SUN.)

PHRAATES (p-hrah-ah'tās) (PHRAHATES), the name of five Parthian kings

1. PHRAATES I, son of Priapatius, reigned *c.* 175–170 B C. He subdued the Mardi, a mountainous tribe in the Elburz (Justin xli. 5; Isid. Charac. 7) He died young, and appointed as his successor not one of his sons, but his brother Mithradates I. (Justin xli. 5).

2. PHRAATES II., son of Mithradates I., the conqueror of Babylonia, reigned 138–127. He was attacked in 130 by Antiochus VII. Sidetes, who, however, in 129 was defeated and killed in a great battle in Media, which ended the Seleucid rule east of the Euphrates (*See* SELEUCID DYNASTY.) Meanwhile the

kingdom was invaded by the Scythians (the Tochari of Bactria), who had helped Antiochus. Phraates marched against them, but was defeated and killed (Justin xlii. 1; Johannes Antioch, *fr.* 66).

3. PHRAATES III., "the God" (Phlegon, *fr.* 12 *ap.* Photius *cod.* 97 and on some of his coins), succeeded his father, Sanatruces, in 70 B.C., at the time when Lucullus was preparing to attack Tigranes of Armenia, who was supreme in western Asia and had wrested Mesopotamia and several vassal states from the Parthian kingdom. Naturally, Phraates declined to assist Mithradates of Pontus and Tigranes against the Romans. (*See* TIGRANES.) He supported his son-in-law, the younger Tigranes, when he rebelled against his father, and invaded Armenia (65 B.C.) in alliance with Pompey, who abandoned Mesopotamia to the Parthians (Dio. Cass. xxxvi. 45, 51; Appian, *Mithr.* 104; Liv. *Epit.* 100). But Pompey soon overrode the treaty; he acknowledged the elder Tigranes, took his son prisoner, occupied the vassal states Gordyene and Osroëne for the Romans, and denied the title of "king of kings," which Phraates had adopted again, to the Parthian king (Plut. *Pomp.* 33, 38; Dio. Cass. xxxvii. 5 *seq.*). About 57 Phraates was murdered by his two sons, Orodes I. and Mithradates III.

4. PHRAATES IV., son of Orodes I., by whom he was appointed successor in 37 B.C., after the death of Pacorus. He soon murdered his father and all his thirty brothers (Justin xlii. 5; Plut. *Crass.* 33; Dio Cass. xlix. 23). He was attacked in 36 by Antonius (Mark Antony), who marched through Armenia into Media Atropatene, and was defeated and lost the greater part of his army. Believing himself betrayed by Artavasdes, king of Armenia, he invaded his kingdom in 34, took him prisoner, and concluded a treaty with another Artavasdes, king of Atropatene. But when the war with Octavianus Augustus broke out, he could not maintain his conquests; Phraates recovered Atropatene and drove Artaxes, the son of Artavasdes, back into Armenia (Dio. Cass. xlix. 24 *seq.*, 39 *seq.*, 44; *cf.* li. 16; Plut. *Antonius*, 37 *seq.*). But by his many cruelties Phraates had roused the indignation of his subjects, who raised Tiridates II. to the throne in 32. Phraates was restored by the Scythians, and Tiridates fled into Syria.

The Romans hoped that Augustus would avenge the defeat of Crassus on the Parthians, but he contented himself with a treaty, by which Phraates gave back the prisoners and the conquered eagles (20 B.C., *Mon. Anc.* 5, 40 *seq.*; Justin xlii. 5); the kingdom of Armenia also was recognized as a Roman dependency. Soon afterwards Phraates, whose greatest enemies were his own family, sent five of his sons as hostages to Augustus, thus acknowledging his dependence on Rome. This plan he adopted on the advice of an Italian concubine whom he made his legitimate wife under the name of "the goddess Musa"; her son Phraates, commonly called Phraataces (a diminutive form), he appointed successor. About 4 B.C. he was murdered by Musa and her son (Joseph. *Ant.* xviii. 2, 4).

5. PHRAATES V., or PHRAATACES, the younger son of Phraates IV. and "the goddess Musa," with whom he is associated on his coins. Under him a war threatened to break out with Rome about the supremacy in Armenia and Media. But when Augustus sent his adopted son Gaius Caesar into the east in order to invade Parthia, the Parthians preferred to conclude a treaty (A.D. 1) by which once again Armenia was recognized as in the Roman sphere (Dio. Cass. lv. 10; Velleius ii. 101). Soon after Phraataces and his mother were slain by the Parthians, about A.D. 5 (Joseph. *Ant.* xviii. 2, 4). (ED. M.)

PHRANTZA, GEORGE [GEORGIOS PHRANTZES] (1401–*c.* 1477), the last Byzantine historian, was born in Constantinople. At an early age he became secretary to Manuel II. Palaeologus, and rose to the position of great logothete (chancellor). At the capture of Constantinople by the Turks (1453) he fell into their hands, but managed to escape to Peloponnesus. After the downfall of the Peloponnesian princes (1460) Phrantza retired to the monastery of Tarchaniotes in Corfu. Here he wrote his *Chronicle*, with an account of the house of the Palaeologi from 1258–1476.

Editions by I. Bekker (1838) in the *Corpus scriptorum hist. byz.*, and in J. P. Migne, *Patrologia graeca*, clvi.; *see* also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

PHRAORTES, the Greek form of *Fravartish*, king of Media. According to Herodotus (i. 102) he was the son of Deioces, and began the Median conquests. He first subjugated the Persians, and then a great many other peoples of Asia, till at last he attacked the Assyrians, but was defeated and killed in a battle, after a reign of 22 years (about 646–625 B.C.; but perhaps, as G. Rawlinson supposes, the 53 years of Deioces ought in reality to be transferred to him). From other sources we obtain no information whatever about Phraortes; but the data of the Assyrian inscriptions prove that Assur-bani-pal (*see* BABYLONIA AND ASSYRIA), at least during the greater part of his reign, maintained the Assyrian supremacy in Western Asia, and that in 645 he conquered Susa. The Medians too were subject to him as far as the Elburz and the central Iranian desert.

When after the assassination of Smerdis all the Iranian tribes, the Babylonians and the Armenians rebelled against Darius and the Persian rule, "a man of the name of Fravartish (*i.e.*, Phraortes), a Mede, rebelled in Media and spoke to the people thus: I am Khshathrita, of the family of Uvakhshatra (Cyaxares)." He reigned for a short time, but was defeated by Hydarnes, and afterwards by Darius himself, taken prisoner in Rhagae (Rai), and executed in Ecbatana (520 B.C.; *see* inscription of Darius at Behistun). (ED. M.)

PHRENOLOGY, the name given to the empirical system of psychology formulated by F. J. Gall, about the year 1800 and developed by his followers, especially by J. K. Spurzheim and G. Combe. The principles upon which it is based are five: (1) the brain is the organ of the mind; (2) the mental powers of man can be analysed into a definite number of independent faculties; (3) these faculties are innate, and each has its seat in a definite region of the surface of the brain; (4) the size of each such region is the measure of the degree to which the faculty seated in it forms a constituent element in the character of the individual; (5) the correspondence between the outer surface of the skull and the contour of the brain-surface beneath is sufficiently close to enable the observer to recognize the relative sizes of these several organs by the examination of the outer surface of the head. It professes primarily to be a system of psychology, but its second and more popular claim is that it affords a method whereby the disposition and character of the subject may be ascertained.

The Faculties and Their Localities.—The system of Gall was constructed by a method of pure empiricism, and his so-called organs were for the most part identified on slender grounds. Having selected the place of a faculty, he examined the heads of his friends and casts of persons with that peculiarity in common, and in them he sought for the distinctive feature of their characteristic trait. Some of his earlier studies were made among low associates, in gaols and in lunatic asylums, and some of the qualities located by him were such as tend to become perverted to crime. These he named after their excessive manifestations, mapping out organs of murder, theft, etc.; but as this cast some discredit on the system the names were changed by Spurzheim, who claimed as his the moral and religious considerations associated with it. Gall marked out on his model of the head the places of twenty-six organs as round enclosures with vacant interspaces. Spurzheim and Combe divided the whole scalp into oblong and conterminous patches (see the accompanying figures) and separated the component faculties of the human mind into two great groups, subdivided as follows:—

I. Feelings, divided into—
  1. Propensities, internal impulses inviting only to certain actions.
  2. Sentiments, impulses which prompt to emotion as well as to action.
    A. Lower—those common to man and the lower animals.
    B. Higher—those proper to man.

II. Intellectual faculties.
  1. Perceptive faculties.
  2. Reflective faculties.

In the following list the localities are appended to the names, which are mostly the inventions of Spurzheim. Gall's names are placed in brackets. For topography, Broca's names are adopted.

Propensities.—1. Amativeness (*Instinct de la génération*),

median, below the inion.

2. Philoprogenitiveness (*Amour de la progéniture*), median, on the squama occipitis.

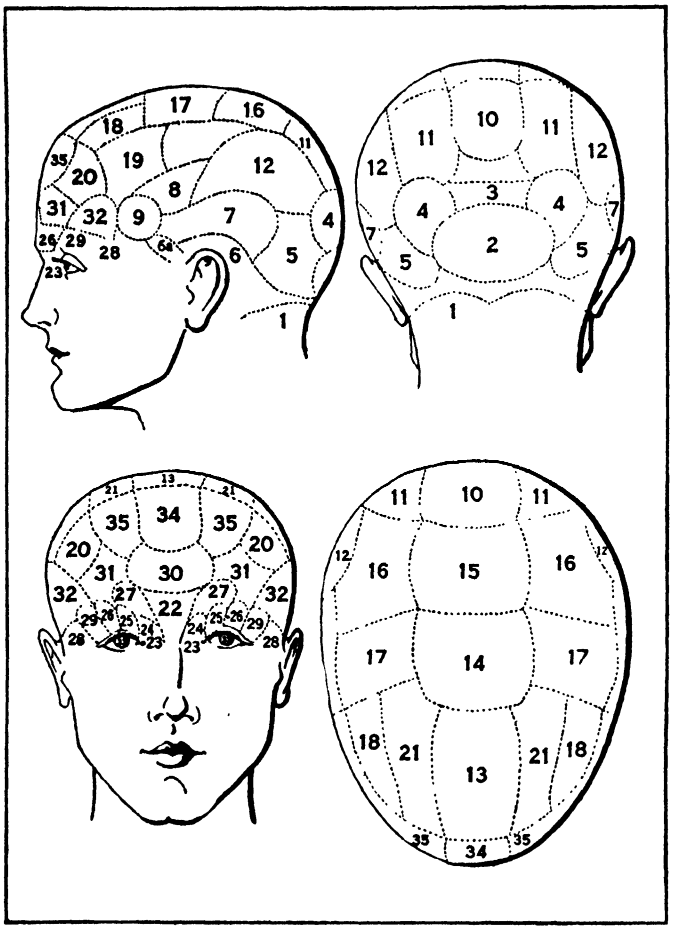
3. Concentrativeness, below the obelion and over the lambda.

4. Adhesiveness (*Amitié*), over the lateral area of the lambdoidal suture.

5. Combativeness (*Instinct de la défense*), above the asterion.

6. Destructiveness (*Instinct carnassier*), above the ear meatus.

6*a*. Alimentiveness, over the temporal muscle and above the ear.



7. Secretiveness (*Ruse, Finesse*), the posterior part of the squamous suture.

8. Acquisitiveness (*Sentiment de la propriété*), on the upper edge of the front half of the squamous suture.

9. Constructiveness (*Sens de méchanique*), on the stephanion. The organ of Vitativeness, or love of life, is supposed by Combe to be seated at the base of the skull.

Lower Sentiments.—10. Self-esteem (*Orgueil, fierté*), at and immediately over the obelion.

11. Love of Approbation (*Vanité*), outside the obelion.

12. Cautiousness (*Circonspection*), on the parietal eminence.

Superior Sentiments.—13. Benevolence (*Bonté*), on the middle of the frontal bone in front of the coronal suture.

14. Veneration (*Sentiment réligieux*), median at the bregma.

15. Conscientiousness, Believingness (Forster), unknown to Gall; recognized by Spurzheim usually from its deficiency, and placed between the last and the parietal eminence.

16. Firmness (*Fermeté*), median, on the sagittal suture from behind the bregma to the front of the obelion.

17. Hope, not regarded as primary by Gall, who believed hope to be akin to desire and a function of every faculty which desires and left this territory unallocated.

18. Wonder, said to be large in vision-seers and many psychic researchers. A second similar organ placed between this and the next is called Mysterizingness by Forster, and is said to be the seat of belief in ghosts and in the supernatural.

19. Ideality (*Poésie*), noted by Gall from its prominence in the busts of poets; said to be the part touched by the hand when composing poetry.

20. Wit (*Esprit caustique*), the frontal eminence.

21. Imitation (*Faculté d'imiter*), disposition to mimicry, placed between Benevolence and Wonder.

Perceptive Faculties.—22. Individuality, over the frontal sinus in the middle line.

23. Form (*Mémoire des personnes*), capacity of recognizing faces; gives a wide interval between the eyes.

24. Size, over the trochlea at the orbital edge.

25. Weight, outside the last on the orbital edge and, like it, over the frontal sinus.

26. Colour, also on the orbital edge external to the last.

27. Locality (*Sens de localité*), placed above Individuality on each side, and corresponding to the upper part of the frontal sinus and to the region immediately above it.

28. Number, on the external angular process of the frontal bone.

29. Order, internal to the last.

30. Eventuality (*Mémoire des choses*), the median projection above the glabella.

31. Time, below the frontal eminence and a little in front of the temporal crest.

32. Tune (*Sens des rapports des tons*), on the foremost part of the temporal muscle.

33. Language (*Sens des mots*), behind the eye.

Reflective Faculties.—34. Comparison (*Sagacité comparative*), median, at the top of the bare region of the forehead.

35. Causality (*Esprit métaphysique*), the eminence on each side of Comparison.

Anatomical and Physiological Considerations.—The teaching of anatomy with regard to phrenology may be summarized thus: (1) the rate of growth of brain is concurrent with the rate of development of mental faculty; (2) there is some degree of structural differentiation as there are varying rates of development of different parts of the cerebral surface; (3) there is no accordance between the regions of Gall and Spurzheim and definite areas of cerebral surface.

That the brain is the organ of the mind is now universally received. While it is probable that certain molecular changes in the grey matter are antecedents or concomitants of mental phenomena, the precise nature of these processes, to what extent they take place, or how they vary among themselves have not as yet been determined experimentally; the occurrence of the change can only be demonstrated by some such coarse method as the altered pulsation of the carotid arteries, the increase of the temperature of the head, the abstraction, during brain-action, of blood from other organs as shown by the plethysmograph, or the formation of lecithin and other products of metabolism in brain-substance.

Psychological Aspect.—There is a large weight of evidence in favour of the existence of some form of localization of function. So little is known of the physical changes which underlie psychical phenomena, or indeed of the succession of the psychical processes themselves, that we cannot as yet judge as to the nature of the mechanism of these centres. So much of the psychic work of the individual life consists in the interpretation of sensations and the translation of these into motions that there are strong a priori grounds for expecting to find that much of the material of the nerve-centres is occupied with this kind of work, but in the present conflict of experimental evidence it is safer to suspend judgment. That these local areas are not centres in the sense of being indispensable parts of their respective motor apparatus is clear, as the function abolished by ablation of a part returns, though tardily, so that whatever superintendence the removed region exercised apparently becomes assumed by another part of the brain. Experimental physiology and pathology, by suggesting other functions for parts of the brain-surface, are thus subversive of many details of the phrenology of Gall and Spurzheim.

The fundamental hypothesis which underlies phrenology as a

system of mental science is that mental phenomena are resolvable into the manifestations of a group of separate faculties. The assumption is contained in the definition that the exercise of a faculty is the physical outcome of the activity of the organ, and in several of the standard works this is illustrated by misleading analogies between these and other organs; thus the organs of benevolence and of firmness are said to be as distinct as the liver and pancreas.

Adverse Conclusions.—"Die Schädellehre ist allerdings nicht so sehr Irrthum in der Idee als Charlatanerie in der Ausführung," says one of its most acute critics. Even though no fault could be found with the physiology and psychology of phrenology, it would not necessarily follow that the theory could be utilized as a practical method of reading character; for, although the inner surface of the skull is moulded on the brain, and the outer surface approximates to parallelism thereto, yet the correspondence is sufficiently variable to render conclusions therefrom uncertain. The spongy layer or diploe which separates the two compact tables may vary conspicuously in amount in different parts of the same skull, as in the cases described by Professor Humphry (*Journ. of Anat.*, viii. 137). The frontal sinus, that *opprobrium phrenologicum,* is a reality, not unfrequently of large size, and may wholly occupy the regions of five organs The centres of ossification of the frontal and parietal bones, the muscular crests of these and of the occipital bones also, differ in their prominence in different skulls Premature synostoses of sutures mould the brain without doing much injury to its parts. In such cases there are compensatory dilatations in other directions modifying sometimes to an extreme degree the relation of brain-surface to skull-surface. The writer has found such displacements in extremely scaphocephalic skulls; the same is true of accidental deformations due to pressure on the infantile skull before it consolidates.

All these and other cogent reasons of a like kind, whose force can be estimated by those accustomed to deal with the component soft parts of the head, should lead phrenologists to be careful in predicating relative brain-development from skull-shape. Psychology, physiology and experience alike contribute to discredit the practical working of the system and to show how worthless the so-called diagnoses of character really are. Its application by those who are its votaries is seldom worse than amusing, but it is capable of doing positive social harm, as in its proposed application to the discrimination or selection of servants and other subordinate officials.

PHRYGIA, the name of a large district of Asia Minor in ancient times, derived from a people whom the Greeks called Φρύγες; *i.e.,* "freemen." Taken at its widest extent, Phrygia comprised the whole north-west and centre of Asia Minor as far as the river Halys and the southern mountain-edge of the peninsula, and had sea fronts on the Black sea and the Aegean. But most ancient authors confined the name to an inland district stretching roughly from long. 29° to 32° or 33°, and from lat. 38° to 40°; and the real core of Phrygia at all times lay in the comparatively small plateau between the river Sangarius and the upper course of the Maeander.

Phrygia in its narrower sense is a table-land 3,000–5,000 ft., dotted with isolated mountains that rise to 8,000ft., and intersected by several river-systems, in particular that of the Sangarius in the north-east, of the upper Hermus in the west, and of the upper Maeander in the south. Its deep-cut valleys are well suited to the cultivation of cereals and of the vine, but in general the rainfall of the country is too scanty and irregular for the growth of crops or of forest, and the dry, bare uplands are best adapted to rough grazing. The mineral wealth of Phrygia is inconsiderable. Iron was formerly worked in the district of Cibyra, mercury, cinnabar and copper in the neighbourhood of Iconium; but the most notable product was the marble of Docimium, a white stone streaked with veins of violet.

The principal line of communications across Phrygia was a route which rose steeply out of the Hermus valley and traversed the entire length of the plateau in a somewhat irregular line, proceeding at first in a north-easterly direction to Dorylaeum, thence eastward past Gordium and Ancyra to the old Hittite capital at Boghaz-Keui. This road eventually formed part of the "Royal road," by which the Achaemenid kings of Persia connected Sardes and the Aegean seaboard with their capital at Susa. It appears at all times to have served a military and administrative rather than a commercial purpose. The southern edge of Phrygia was crossed by another trunk road which ascended the valley of the Lycus (a tributary of the Maeander) to Apameia-Celaenae, and thence led to Iconium and across Mt Taurus into Syria. This route was much used by the Seleucid kings of Syria and by the Romans, and was probably at every period the chief line for commercial traffic to the Aegean sea. The scenery of Phrygia is generally monotonous Even the mountainous districts rarely show striking features or boldness of character

The Phrygian Immigration.—It may be taken for granted that the population of Phrygia always contained a large element of that indigenous "Asianic" stock, whose survival to the present day has been noted by modern travellers. The persistence of this element in ancient times is indicated by the continued prevalence of native Asianic cults in Phrygia (*See* p. 853) But the Phrygians properly so-called were an immigrant folk According to Greek tradition they entered Asia Minor from Thrace or Macedonia; and this tradition is confirmed by the fact that their language was certainly Indo-European

For the date of the Phrygian immigration the best evidence is found in Homer, who represents the Phrygians as rendering aid to King Priam at the siege of Troy, in return for assistance which he had given to them in their wars against the Amazons (=the Hittites?) on the banks of the Sangarius This story indicates that the Phrygians had entered Asia Minor some time before 1200 B.C. A date not later than 1500 B.C. has been inferred from the furniture of certain burial-mounds in north-western Asia Minor, which resemble the contents of Macedonian tumuli of the early second or late third millennium

It would appear from Homer that the incoming Phrygians made their principal settlement in the Sangarius valley Their chief surviving monuments are also found in this valley (at Gordium), and on the adjacent plateau to the south-west of the Sangarius. But it is probable that about 1000 B.C. all the northern and central parts of Asia Minor had come under Phrygian occupation. The extension of Phrygian power to the western seaboard of Asia Minor may be inferred from a somewhat enigmatic Greek tradition, that in the 9th century B.C. they exercised a "thalassocracy" or "lordship of the seas" in Aegean waters, and from the abundance of Phrygian remains on Mt. Sipylus in the lower Hermus valley. The description of Sinope as a "Phrygian" town indicates a Phrygian settlement along the Black sea. Another Greek tradition, that the Armenians were an offshoot of the Phrygian stock, is supported by the resemblance between the

Phrygian and the Armenian tongues.

The expansion of the Phrygians into eastern Asia Minor is proved by the discovery of an inscription in the Phrygian language at Tyana in Cappadocia. This text, it is true, does not appear to be of earlier date than the 8th century B.C. But the presence of Phrygians on the borders of the Euphrates may perhaps be inferred from Assyrian records which relate victories by Tiglath-Pileser I. (*c.* 1120 B.C.) and by Sargon (717–709 B.C.) over a tribe named the Mushki. The fact that in one of Sargon's inscriptions the chief of the Mushki bears the name "Mita" suggests that the Mushki were Phrygian, or at least had Phrygian rulers, for "Mita" or "Midas" was a common name among the kings of Phrygia proper.

The relation between the Phrygians and the Hittites, who were the predominant people in Asia Minor *c.* 1500 B.C., is not yet quite clear. The existence of a group of rock-carvings in Hittite style, extending from Ancyra to Sardes and Smyrna, suggests that Phrygia proper may at one time have been under Hittite government, but the character of Hittite influence in northwestern Asia Minor still remains uncertain. On the other hand there is little doubt that the decline of Hittite culture and the disappearance of Hittite power from Asia Minor after 1000 B.C. was in large measure due to the expansion of the Phrygians over the peninsula.

Decline of Phrygia.—About 1000 B.C. the Phrygians had penetrated southward in Asia Minor as far as the Hermus and the Maeander, and eastward to the Halys, if not to the Euphrates. But over the greater part of this territory they were unable to consolidate their power, or to extend their culture. East of the Halys they disappear from history about 700 B.C. Their frontage on the Black sea was taken from them by the Bithynians, who probably entered Asia Minor from Europe soon after 1000 B.C. Their access to the Aegean was shut off at some unknown date by the Greek colonists of the coastland and by the Lydians of the Hermus valley. After 800 B.C. the only districts which remained in Phrygian occupation were the tableland between the Sangarius and the Hermus, and the borderland of the Dardanelles and the Sea of Marmora, known later as "Hellespontine Phrygia."

In the 8th century B.C. Phrygia proper achieved a considerable measure of prosperity under a line of kings who had their capital at Gordium and were called alternately "Gordius" and "Midas." The last and greatest of this dynasty was a king Midas who reigned, according to Greek chronologers, from 738 to 695 B.C. This ruler cultivated close relations with the Greeks. He was the first foreign ruler to dedicate offerings to Apollo at Delphi, and he took to wife the daughter of Agamemnon, king of the Aeolic Greek city of Cyme. His name may still be read on his tomb in the "Midas city," one of the most notable remains of Phrygian art.

Soon after 700 B.C. the reign of Midas was brought to a sudden end by the incursion of a Thracian people named the Cimmerians, of which Greeks, Lydians and Assyrians felt the force, but the Phrygians took the full brunt. By the second half of the 7th century the Cimmerians disappeared from Asia Minor without leaving a trace, but Phrygia was now so far enfeebled that it fell under the dominion of the neighbouring kingdom of Lydia.

Phrygia under Foreign Rule.—Under the Lydian rule Phrygia seems to have recovered some of its former prosperity. If the dates usually assigned to Phrygian monuments are correct, Phrygian art reached its highest development about 600 B.C. A resumption of commerce with the Greeks at this period is indicated by finds of Corinthian pottery at Gordium. But after the conquest of Lydia by the Persians (546 B.C.) Phrygia shared in the general decline which now befell western Asia Minor; nothing more is heard of its trade with the Greeks, except that it was a favourite hunting-ground for Greek slaves. It formed one large Persian province, but about 400 B.C. it was divided into two portions, "Great Phrygia" and Hellespontine Phrygia.

After two centuries of uneventful history under Persian rule Phrygia passed into the hands of Alexander of Macedon, who visited Gordium (333 B.C.) and there cut the "Gordian knot"; legend declared that this knot, which secured the yoke to the shaft of an archaic farm-wagon, had been tied by Gordius, the founder of the Phrygian dynasty, and that whosoever might unravel it should become lord of Asia. After Alexander's death Phrygia became a battle-ground for the contending forces of his former marshals. At first it formed the nucleus of the territory of Antigonus, who set up his capital at Celaenae; but after the decisive action at the neighbouring site of Ipsus (301 B.C.) it was transferred to Seleucus as an annex to the kingdom of Syria.

About 275 B.C. all the Phrygian lands east of the Sangarius came into the possession of a horde of Celtic invaders from the Danube lands and was renamed Galatia. The western portion of Phrygia at the same time was taken from the kings of Syria by the newly-founded monarchy of Pergamum. For nearly a century the Phrygian territory remained a bone of contention between the kings of Pergamum and Syria and the Galatian Celts, until in 189 B.C. the Romans expelled the Syrian kings from Asia Minor, confined the Celts to Galatia, and left the western half of the peninsula under the undisputed control of the Pergamene rulers. After the annexation of the Pergamene kingdom by Rome in 133 B.C., Phrygia west of the Sangarius became part of the province of Asia, and remained in this condition until *c.* A.D. 300, when the emperor Diocletian constituted it into two independent provinces, Phrygia Prima and Secunda. Under the Byzantine empire the name Phrygia disappeared altogether.

ECONOMIC LIFE AND CULTURE

Economic Conditions.—Phrygia was at all times an agricultural and, still more, a pastoral land. The only industrial products of greater importance were the marble of Docimium, which was exported in large quantities to Rome under the empire, and the dark-coloured woollens of Laodiceia and Colossae (in South Phrygia, on the River Lycus). The southern border of Phrygia, as we have seen, was traversed by a trade route which, in the days of Greek and Roman rule, attained considerable importance. On the other hand the Royal road, which ran through the heart of Phrygia, played no great part as a highway of commerce, and there is no evidence of any notable quantity of traffic having been carried along the valley of the Sangarius. Phrygia's chief source of wealth lay in its grasslands, which produced fine breeds of horses and of sheep. The horses were exported as far as Rome for use in the circus. The sheep provided a clip of wool which supplied the looms, not only of Phrygia itself, but also of Miletus, Pergamum and other Greek centres of the textile industry.

Under economic conditions such as these, Phrygia was always a land of villages rather than of cities. In the days of the native monarchy Gordium and the "Midas city" grew to be considerable towns, and Celaenae (subsequently renamed Apameia) was probably at all times a trading centre of some importance. Under the rule of the Syrian and Pergamene dynasties a number of new cities with a predominantly Greek population were founded, but most of these were little more than garrison towns or settlements of veterans: the only places that require mention here are the industrial cities of Laodiceia and Colossae (noticed above). The villages were usually built on the slopes of the lower hills, near the site of a temple or of a great landowner's manor-house. The soil for the most part belonged to the successive kings or overlords of the country, to their principal vassals, and to the priesthoods of the more important temples. The actual cultivators lived mostly in a condition of serfdom.

Culture.—The history of Phrygian art is not easy to trace, because the chronological order of the surviving monuments is not yet certain. Its most typical products are rock-cut tombs and houses, and ornamented rock-façades. The entrances to the tombs are often decorated with a gable like that of a Greek temple, supported on pillars in a primitive Dorian or Ionic style. The subjects most commonly represented in the sculptured reliefs are the native goddess Cybele, and pairs of rampant lions, heraldically opposed. Another characteristic ornament consists of a maeander pattern carved in flat relief. The native pottery is ornamented with geometric patterns in matt paint. In the relations of Phrygian art to that of other peoples the one clear point

is that its technique of rock-carving bears close resemblance to that of the Hittites, as exhibited at Boghaz-Keui and in eastern Asia Minor, and was probably borrowed from this people. The maeander patterns, which are no doubt in imitation of tapestry work, also appear to have been derived from Hittite models, and it was perhaps through a Hittite medium that the heraldic lions and the Ionic pillars were introduced into Phrygia from Mesopotamia. The gables and the Doric columns of the Phrygian rock-tombs are strongly reminiscent of archaic Greek art, and it is not unlikely that they are Greek in origin. In general, the Phrygian artists were not inventive, but they knew how to adapt to their own uses whatever they borrowed from their neighbours.

Phrygian music is only known to us from the descriptions of Greek critics, who considered it too florid and exciting. Its favourite instrument was a double flute, which the Greeks regarded as the prototype of their own *aulos*. But the double flute was also known in prehistoric Crete, and can therefore not be regarded as a Phrygian invention.

The alphabetic script of the Phrygians bears a closer resemblance to archaic Greek than to Phoenician; but its exact relation to either of these has not yet been determined. It is only represented by a few texts: all the later inscriptions from Phrygia are in Greek or Latin characters. The Phrygian tongue, which may best be studied in the fairly numerous texts (mostly epitaphs) of the early centuries A.D., is akin to Armenian. In the period of Greek and Roman rule it gave way to Greek in the towns, but on the countryside it remained in use until the 5th or 6th century A.D. (*See* ASIANIC LANGUAGES.)

Religion.—The religion of Phrygia was plainly a composite product. The Phrygian immigrants of *c.* 1200 B.C. brought with them several typical Indo-European gods, such as Papas, the equivalent of the Greek Zeus, and Men, a male moon-deity. The god Sabazius, who was usually equated by ancient writers with the Thracian Dionysus, may be referred to the same group. But the gods of the Phrygian invaders were never able to displace the original Asianic deities, of whom the foremost were Cybele, the "Great Mother," and Attis, a youth who died untimely but in death retained his beauty of figure. This couple, which had several parallels in the religions of the Near East, evidently represented the generative force of nature and the vegetation that withers and blooms with each new season. The worship of these deities was highly orgiastic, and their priests, the so-called "galli," carried their devotion to the point of self-mutilation. The principal sanctuary of Cybele stood at Pessinus, by Mt. Dindymus in central Phrygia, where a hierarchy of priests exercised theocratic rule over the inhabitants of the extensive temple estates. Not only did the cult of Cybele and Attis maintain itself against the religion of the Phrygian newcomers, but it partially absorbed them. Nay more, it more than held its own against the religions of Greece and Rome, and it competed against these on European soil. The worship of Cybele spread to Greece in the 5th century B.C.; in 204 B.C. it was officially established at Rome; in the days of the Roman empire it was carried on the tide of oriental immigration into every part of Italy and penetrated the western provinces as far as the Rhineland and Britain. Thus the religion of Phrygia was its most distinctive contribution to ancient Mediterranean civilization. The influence of the native Asianic religion may also be traced in the various heresies, and especially the heresy of Montanus (himself a Phrygian), that arose in Phrygia after the spread of Christianity. Nevertheless the conversion of Phrygia to Christianity was remarkably early and complete. Christian inscriptions begin there in the 2nd century and are abundant in the third. In all probability the mass of the people had been converted by 300, and Eusebius is no doubt correct in saying that in one Phrygian city at that time every soul was a Christian.

BIBLIOGRAPHY.—(*a*) *Topography and Monuments.*—Recent records of exploration will be found in the numerous books and articles of Sir William Ramsay, especially in his *Cities and Bishoprics of Phrygia* (1895–97), and in the *Journal of Hellenic Studies* (1882 ff.). The results of the German excavations at Gordium are set forth in Körte, *Gordion* (1904). Much useful information will be found in D. G. Hogarth's chapters in the *Cambridge Ancient History,* vols. ii. and iii. (1924–25). (M. C.)

PHRYNE, Greek courtesan, lived in the 4th century B.C. Her real name was Mnesarete, but owing to her complexion she was called Phryne (toad). She was born at Thespiae in Boeotia, but seems to have lived at Athens. She acquired so much wealth that she offered to rebuild the walls of Thebes, on condition that the words "Destroyed by Alexander, restored by Phryne the courtesan," were inscribed upon them. On the occasion of a festival of Poseidon at Eleusis she laid aside her garments, let down her hair, and stepped into the sea in the sight of the people, thus suggesting to the painter Apelles his great picture of Aphrodite Anadyomene, for which Phryne sat as model. She was also (according to some) the model for the statue of the Cnidian Aphrodite by Praxiteles. When accused of profaning the Eleusinian mysteries, she was defended by the orator Hypereides. When it seemed as if the verdict would be unfavourable, he rent her robe and displayed her bosom, which so moved her judges that they acquitted her. A statue of Phryne, the work of Praxiteles, was placed in a temple at Thespiae by the side of a statue of Aphrodite by the same artist.

See Athenaeus, pp. 558, 567, 583, 585, 590, 591; Aelian, *Var. Hist.* ix. 32; Pliny, *Nat. Hist.* xxxiv. 71.

PHRYNICHUS. 1. Son of Polyphradmon and pupil of Thespis, one of the earliest of the Greek tragedians. Some of the ancients, indeed, regarded him as the real founder of tragedy. He gained his first poetical victory in 511 B.C. His most famous play was the *Capture of Miletus.* The audience was moved to tears, the poet was fined for reminding the Athenians of their misfortunes, and it was decreed that no play on the subject should be produced again. In 476 Phrynichus was successful with the *Phoenissae,* celebrating the victory of Salamis and especially the deeds of Themistocles, who was choragus. Phrynichus is said to have died in Sicily. He introduced a separate actor as distinct from the leader of the chorus, and thus laid the foundation of dialogue. But in his plays, as in the early tragedies generally, the dramatic element was subordinate to the chorus. According to Suïdas, Phrynichus first introduced female characters on the stage (played by men in masks), and made special use of the trochaic tetrameter.

Fragments in A. Nauck, *Tragicorum graecorum fragmenta* (1887).

2. A poet of the Old Attic comedy and a contemporary of Aristophanes. His first comedy was exhibited in 429 B.C. He composed ten plays, of which the *Solitary* (Μονότροπος) was exhibited in 414 along with the *Birds* of Aristophanes, and gained the third prize. The *Muses* carried off the second prize in 405, Aristophanes being first with the *Frogs,* in which he accuses Phrynichus of employing vulgar tricks to raise a laugh, of plagiarism and bad versification.

Fragments in T. Kock, *Comicorum atticorum fragmenta* (1880).

3. PHRYNICHUS ARABIUS, a grammarian of Bithynia, lived in the 2nd century A.D. According to Suïdas he was the author of (1) an *Atticist,* in two books; (2) Τιθεμένων συναγωγή, a collection of subjects for discussion; (3) Σοφιστική παρασκευή or Sophistical Equipment. The work was learned, but prolix and garrulous. A fragment contained in a Paris ms. was published by B. de Montfaucon, and by I. Bekker in his *Anecdota graeca* (1814). Another work of Phrynichus, not mentioned by Photius, but perhaps identical with the *Atticist* mentioned by Suïdas, the *Selection* (Ἐκλογή) *of Attic Words and Phrases,* is extant. It is a collection of current words and forms which deviated from the Old Attic standard, and is interesting as illustrating the changes through which the Greek language had passed between the 4th century B.C. and the 2nd century A.D.

Editions of the Ἐκλογή, with valuable notes, have been published by C. A. Lobeck (1820) and W. G. Rutherford (1881); Lobeck devotes his attention chiefly to the later, Rutherford to the earlier usages

noticed by Phrynichus. *See* also J. Brenous, *De Phrynicho Atticista* (1895).

4. An Athenian general in the Peloponnesian War. He took a leading part in establishing the oligarchy of the Four Hundred at Athens in 411 B.C., and was assassinated in the same year (Thucydides viii.).

PHTHALIC ACIDS, the name given to the three isomeric benzene-dicarboxylic acids, $C_6H_4(CO_2H)_2$: (1) ortho, or phthalic acid; (2) meta, or *iso*phthalic acid; (3) para, or terephthalic acid. The most important is the first, as it forms the starting material in the production of many synthetic dyes and of the synthetic resin, glyptal, glyceryl phthalate.

Phthalic acid was obtained by Laurent in 1836 by oxidizing naphthalene tetrachloride, and, believing it to be a naphthalene derivative, he named it naphthalenic acid; Marignac showed Laurent's supposition to be incorrect, upon which Laurent gave it its present name. It was formerly manufactured by oxidizing naphthalene tetrachloride (prepared from naphthalene, potassium chlorate and hydrochloric acid) with nitric acid, or by oxidizing the hydrocarbon with fuming sulphuric acid, using mercury or mercuric sulphate as a catalyst (German pat. 91,202). These methods have been superseded by a catalytic process in which air and naphthalene vapour are passed over heated vanadium pentoxide; the yield is upwards of 80% of phthalic anhydride, which is readily separated by fractional sublimation from unchanged naphthalene. Phthalic acid forms white crystals, melting at 213° with decomposition into water and phthalic anhydride; the latter forms long white needles, melting at 128° and boiling at 284°. Heated with an excess of lime it gives benzene; calcium benzoate results when calcium phthalate is heated with one molecular proportion of lime to 330°–350°. The acid (and anhydride) are largely used in the colour industry. (*See* FLUORESCEIN; PHENOLPHTHALEIN; DYES, SYNTHETIC.)

Phthalyl chloride, $C_6H_4(COCl)_2$ or $C_6H_4(CCl_2)(CO)O$, formed by heating the anhydride with phosphorus pentachloride, is an oil solidifying at 0° and boiling at 275°. In some reactions it behaves as having the first formula, in others as having the second. Phthalyl chloride with phosphorus pentachloride gives two phthalylene tetrachlorides, one melting at 88° and the other at 47°. They cannot be changed into one another, and have been given the formulae $C_6H_4(CCl_3)(COCl)$ and $C_6H_4(CCl_2)_2O$. Phthalimide, $C_6H_4(CO)_2NH$, is formed by heating phthalic anhydride or chloride in ammonia gas or by molecular rearrangement of ortho-cyanobenzoic acid. It forms *N*-metallic and alkyl salts. Bromine and potash or alkaline hypochlorite give anthranilic acid, $C_6H_4(NH_2)(CO_2H)$. (*See* INDIGO.)

Isophthalic acid is obtained by oxidizing meta-xylene with chromic acid, or by fusing potassium meta-sulphobenzoate, or meta-bromobenzoate with potassium formate (terephthalic acid is also formed in the last case). It melts above 300°, and dissolves in 7,800 parts of cold water and in 460 of boiling. The barium salt ($+6H_2O$) is very soluble (unlike the barium salts of phthalic and terephthalic acids).

Terephthalic acid, formed by oxidizing para-diderivatives of benzene, or best by oxidizing caraway oil, a mixture of cymene and cuminol, with chromic acid, is almost insoluble in water, alcohol and ether; it sublimes without melting when heated.

PHTHISIS (tī'sĭs), a name formerly given (like "Consumption") to the disease of the lung now known as Tuberculosis (*q.v.*) from the wasting often observed. This wasting, however, depends mainly upon secondary infection of tuberculous areas by pyogenetic micrococci and is accompanied by much fever and profuse sweating. The modern tendency is to use the term "phthisis" only when implying the existence of this double infection.

PHYLACTERY, a term applied in Matt. xxiii. 5 to the *tefillin* of the Jews on the assumption that these were amulets (φυλακτήρια), against physical evil. *Tefillin,* either from טָפַל, to attach, or פָּלַל, whence תְּפִלָּה, prayer, are certain Pentateuchal texts which, in accordance with Exod. xii. 16 and Deut. vi. 5–9, were to be worn as constant reminders of God during the daily avocations. Hence they were not used on Sabbaths and festivals, as the day itself was a reminder and the schools and markets were closed. The idea of such an outward sign is common. The modern habit of wearing a cross on a watchchain may be compared. Romans had tablets for memoranda hanging from the wrists. Isaiah xlix. 16 evidently denotes this custom. Possibly the origin is to be sought in tattooing. Tefillin are worn on the hand and head, the verses being enclosed in leather boxes fixed in position by leather thongs. The hand phylactery has one compartment, in which the texts figure on one parchment, the head phylactery having four such compartments, each with one text. The extracts are Ex. xiii. 1–10:11–16; Deut. vi. 4–9, xi. 13–21.

BIBLIOGRAPHY.—For further details, illustrations and historical and critical views, see *Jewish Encyclopedia, s.v.* For the prayers and meditations, *see* S. Singer's *Authorized Daily Prayer Book*, pp. 19 *sqq.* For certain Jewish objections *see* A. Asher's *Collected Writings,* pp. 80–89 (1916, privately printed). Linked with *Tefillin* are the *Mezūzah* (door text) and *Çiçith* (fringes). The former is a text containing Deut. vi. 4–9 rolled in a glass or metal tube on the right-hand of each door, so that everyone who enters or leaves shall think of God (see *Jew. Enc. s.v.* Singer, *op. cit.*, p. 292). The latter (see *Jew. Enc. s.v.* Fringes) is based on Numbers xv. 37–41, which ordains the knotted tassel as a mnemonic.

PHYLE, a mountain fortress, on a pass leading from Athens into Boeotia on the south-west end of Mt. Parnes; famous for its occupation by Thrasybulus at the head of the Athenian exiles during the rule of the Thirty Tyrants in 404 B.C. Defending himself with the help of a snowstorm, he succeeded by a night march in seizing Munychia.

PHYLLITE, in petrology, a group of rocks which are in practically all cases metamorphosed argillaceous sediments, consisting essentially of quartz, chlorite and muscovite, and possessing a well-marked parallel arrangement or schistosity, so called from Gr. φύλλον, a leaf, probably because they yield leaf-like plates, owing to their fissility. They form an intermediate term in the series of altered clays or shaly deposits between clay-slates and mica-schists. The clay-slates have a very similar mineral constitution to the phyllites, but are finer grained and are distinguished also by a very much better cleavage; in the phyllites also white mica (muscovite or sericite) is more abundant as a rule than in slate, and its crystalline plates are larger; the abundance of mica gives these rocks a glossy sheen on the smooth planes of fissility.

A microscopical section of a typical phyllite shows green chlorite and colourless mica, both in irregular plates disposed in parallel order, with a greater or smaller amount of quartz which forms small lenticular grains elongated parallel to the foliation. Grains or iron oxide (magnetite and haematite) and black graphitic dust are very commonly present. Felspar is absent or scarce, but some phyllites are characterized by the development of small rounded grains of albite, often in considerable numbers. The minute needles of rutile, so often seen in clay-slates, are not often met with in phyllites, but this mineral forms small prisms which may be intergrown with black magnetite; at other times it occurs as networks of sagenite. Other phyllites contain carbonates (usually calcite but sometimes dolomite) in flat or spindle-shaped crystals, which often give evidence of crushing. Very tiny blue needles of tourmaline are by no means rare in phyllites, though readily overlooked. Garnet occurs sometimes, a good example of the garnetiferous phyllite being furnished by the whetstones of the Ardennes, in which there are many small isotropic crystals of manganesian garnet. Hornblende, often in branching feathery crystals, is a less frequent accessory. In some phyllites a mineral of the chloritoid group makes its appearance; this may be ottrelite, sismondine or other varieties of chloritoid, and occurs in large sub-hexagonal plates showing complex twinning, and lying across the foliation planes of the rock.

The structural variations presented are comparatively few. The most finely crystalline specimens have generally the most perfect parallel arrangement of their constituents. The foliation is generally flat or linear, but in some rocks is undulose or crumpled. From the imperfection of their cleavage phyllites are rarely suitable for roofing materials; their softness renders them valueless as road stones, but they are not uncommonly employed as inferior building materials. They are exceedingly common in all parts of the world where metamorphic rocks occur; as in the

Scottish Highlands, Cornwall, Anglesey, north-west Ireland, the Ardennes, the Harz Mountains, Saxony, the Alps, Norway, the Appalachians, the Great Lakes district in America, etc.

(J. S. F.)

PHYLLOXERA, a genus of insects belonging to the group Phylloxerinae of the family *Aphididae* which comprises the aphides (*q.v.*) or plant lice. The Phylloxerinae are sometimes placed in a separate family of their own, since they differ from true aphides in characters exhibited in the wing-veins, and also in the fact that the parthenogenetic forms lay eggs instead of producing living young. The genus *Phylloxera* includes over 30 species, the best known being the grape Phylloxera (*P. vastatrix*), which is native to the United States. It was imported into Europe between 1858 and 1863, when American vines were brought over for grafting purposes, and has since reached almost every vine-growing country in the world. The first definite European record was in England in 1863; soon afterwards it was identified in France where it rapidly spread through the vineyards of that country. By 1885 it had extended to most other European grape-producing countries and had reached Algeria, Australia, and the Cape. It was first discovered in California in 1880, but there is evidence that it was present in that State from about 1858, being introduced along with American vines from east of the Rocky Mountains. It was the advent of the highly susceptible European grape that led to the Phylloxera becoming a pest in the Californian vineyards. The presence of this insect is manifested by the vines being stunted and bearing smaller and fewer leaves. When the disease is advanced the leaves are discoloured and galls are present on their under surface. These galls are wrinkled and hairy and their cavity communicates by means of an opening upon the upper surface of the leaf. If the roots be examined, numerous knotty swellings are found upon the smaller rootlets; at first yellowish in colour and fleshy, they finally assume a brown or black colour and become rotten. At the same time the grapes themselves are arrested in their growth and their skins become wrinkled. The damage wrought by the Phylloxera is occasioned by the extraction of the sap by means of the piercing suctorial mouth-parts of this insect, and the subsequent deformation of the plant that is brought about. Millions of acres of vineyards have been destroyed by this pest, and, when at its worst in France, it is stated to have ruined 2,500,000 acres which represented an annual loss in wine-products of £50,000,000.

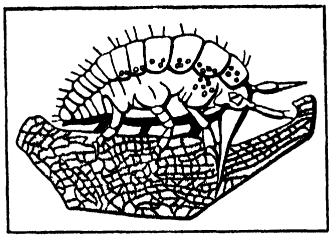

FIG. 1.—ROOT INHABITING FORM OF THE PHYLLOXERA, WITH ITS PROBOSCIS INSERTED INTO TISSUE OF ROOT OF VINE

The complete life-history of Phylloxera is briefly as follows: A single egg is laid by the fertilized female on the bark of the vine where it passes the winter. It hatches in spring into a wingless female or *fundatrix* which, creeping into an opening bud of the vine, forms a gall on the young leaf and lays therein a number of eggs. The latter develop into further wingless forms or *gallicolae* which multiply rapidly and produce new generations of gall-formers on the leaves. Among their progeny there appear, later in the season, wingless females of different behaviour, the *radicolae* (fig. 1), which pass to the roots. The *radicolae* continue reproducing generations of their own kind, but among them winged migrants (fig. 2) eventually appear. These occur from July until October and fly to other vines where they lay two kinds of eggs—small male-producing eggs and large female-producing eggs. The true sexual forms derived from these eggs (fig. 3) are small wingless individuals with vestigial mouth-parts and an aborted alimentary canal. Fertilization takes place and each fertilized female deposits a single over-wintering egg which hatches into a fundatrix as already described. All the rest of the reproduction of the species is by means of parthenogenesis (*q.v.*).

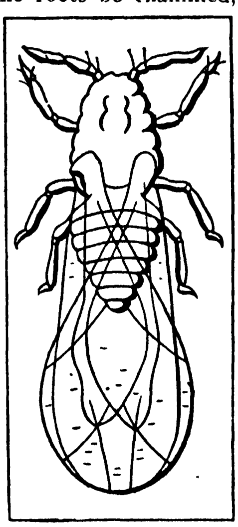

FIG. 2.—WINGED MIGRANT FEMALE
Hatched from the egg of the root Phylloxera, this form flies to other vines where it lays parthenogenetically, eggs of two kinds, male and female

It is noteworthy that in Europe and California the fundatrices

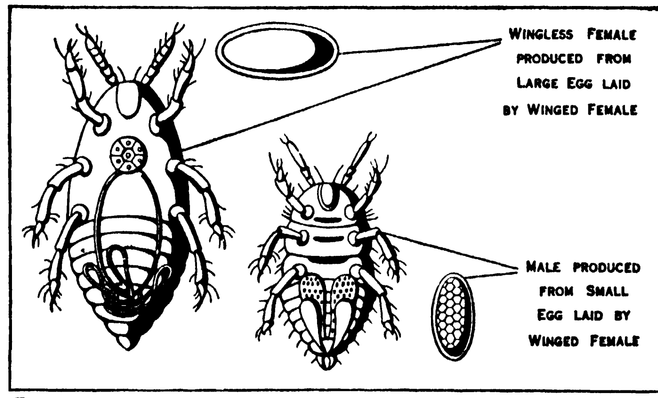

FIG. 3.—MALE AND FEMALE FROM EGGS LAID BY WINGED MIGRANT FEMALE
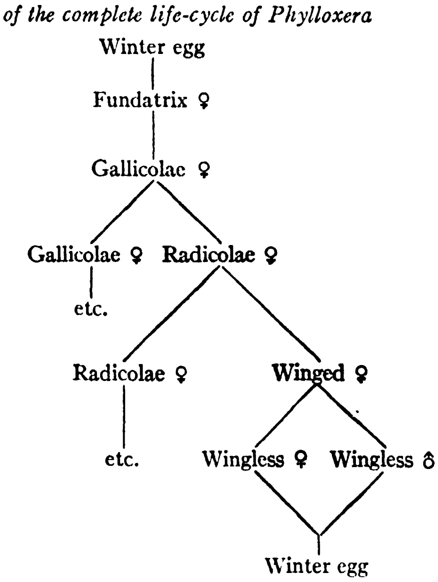
The female dies after laying a single egg which hatches out in the spring as a female insect known as a fundatrix. This form produces eggs from which are hatched gallicolae. Some of these remain in the buds while others descend to the roots as radicolae

usually fail to develop in the absence of certain American vines and the gallicolae generations are consequently rare. Reproduction and spread are brought about by the radicolae, many of which hibernate and continue multiplying in spring. According to the German authority Boerner, there is a race of Phylloxera found in Lorraine which produces galls on European vines, but not on most American varieties, and he has given this Lorraine race the distinctive name of *pervastatrix.*

Scheme of the complete life-cycle of Phylloxera



Many control measures have been suggested against the Phylloxera but few have been generally adopted in practice. The enforcement of quarantine regulations precluding the distribution of rooted vines from infested areas is important. The utilization of vine-stocks less susceptible to the root-feeding form of the insect is generally recognized. Varieties of American grapes, such as *Vitis riparia, V. rupestris, V. berlandieri* and their hybrids, are not seriously injured by the radicolae, and by growing these varieties, or using them as stocks upon which the susceptible European varieties have been grafted, injuries by the pest have been greatly reduced. In certain cases the injection of carbon bisulphide into the soil to kill the root form of the insect has been profitable. The flooding of infested vineyards has been a recog-

nized procedure where conditions are favourable.

BIBLIOGRAPHY.—The literature on the Phylloxera is voluminous. Valéry Mayet, *Les Insectes de la Vigne* (1890); B. Grassi, "The Biology of the Vine Phylloxera" (*Monthly Bulletin of Agric. Intelligence and Plant Diseases*, vol. vi., 1915); W. M. Davidson and R. L. Nougaret, "The Grape Phylloxera in California" (*Bulletin 903, U.S. Dept. of Agriculture*, 1921), are among the less technical writings. For a full bibliography *see* B. Grassi, *Contributo alla Conoscenza delle Fillosserine* (1912). (A. D. I.)

PHYSHARMONICA, a keyboard instrument fitted with free-reeds, a kind of harmonium much used in Germany. It resembles a small harmonium, but differs from it in having no stops. The physharmonica was invented in 1818 by Anton Häckel, of Vienna.

PHYSICAL CULTURE is the development of the body by exercise to promote and maintain good health or to correct defects or weaknesses of the body. Benefit to the body is the main object and recreation derived therefrom is incidental. Physical culture in its simplest form is taking exercises such as setting-up exercises or calisthenics. The use of equipment—dumb-bells, wands or weight machines—though not necessary, adds interest and variety to the exercises.

Development.—The value of exercise to promote health and physical strength has probably always been recognized by mankind. In ancient and mediaeval times building up of the body was principally for purposes of war, or, as in ancient Greece, preliminary training for sports. Systematic physical culture first appeared during the last part of the 18th century in Germany. In 1774, Basedow founded at Dessau a school in which running, wrestling, riding and manual labour were prescribed as exercise for the students. In 1785, Guts Muth started a system of gymnastics in a school near Gotha, and in 1793 published a book, *Gymnastics for the Young*. At about the same time Nachtigall in Denmark, and Ling in Sweden, were introducing physical training in those countries.

To Professor Ludwig Jahn of Germany should probably go the greatest credit for organizing physical training on a broad scale for the benefit of all the people of the country. Under the direction of Jahn, boys, youths and men of all classes of society took part in exercises for physical development throughout Germany (about 1810). Even with Jahn the idea was physical culture with the ultimate object of physically strengthening the manpower of Germany for war. Physical culture first appeared in the United States and England about 1825, and probably in other European countries at about the same time. It developed slowly between 1825 and 1875. Since 1875, due to the rapid growth of the machine, mechanical transportation and labour-saving devices, the occupations of millions of adults have changed from manual labour to office work; the play of children has been restricted in large densely populated cities, thus the necessity for and practice of physical culture has grown rapidly.

General Rules.—From 10 to 15 minutes daily is sufficient for physical culture exercises; preferably in the middle of the morning or in the afternoon. Exercise immediately before or after a meal should be avoided. Children should be given exercises under the supervision of teachers or parents. If the exercise must be taken before breakfast it should be immediately after rising and be followed by a warm bath and dressing leisurely; if the daily bath is taken at night the exercises should precede the bath. The air in the room should be fresh but not chillingly cold. Clothing should be light and loose. All parts of the body should be exercised during each period even when the object is to strengthen a particular part, but no part should be given more than two exercises in succession. For example, take an arm exercise, a trunk exercise, a leg exercise, etc., following some system of rotation. After an exercise that causes muscular strain, take one that loosens the muscles. Take the breathing exercise at the middle and end of the period. The exercises may be made harder by going to full positions, increasing the cadence or number of repetitions and by the use of equipment. They may be made easier by going to quarter positions and executing slowly. For those who are old or weak the milder exercises should be selected, and regulated to result in good circulation of the blood and loosening up and exercising the muscles without exhaustion.

Attention.—Start the exercises from the position of attention, heels together and on the same line, toes turned out equally at about 45°, weight resting on the balls of the feet, legs straight but not stiff, hips level, stomach drawn in, chest raised, back straight, shoulders back and sloping equally, neck and head vertical, chin raised, body and mind alert. In moving the shoulders back keep the stomach drawn in; otherwise a swayed back position will result. Standing with the back to a flat wall and attempting to make the back touch it from head to heel will indicate how the stomach must be drawn in to make the back straight. Repeat each exercise from 5 to 15 times. Words in parentheses, below, indicate parts of the body that will be benefited.

Exercises. *Arms Sideward*—horizontal, palms down, fingers extended and joined, arms stretched; (1) Close fists; (2) spread fingers to fullest extent. Repeat ten times. Variations: Move wrists up and down, or right and left, or with a rotary motion. (Fingers, wrists, biceps.)

Arms to Thrust—forearms horizontal and parallel at waist, elbows back, fists closed, back of hands down; (1) Thrust arms to front horizontal, palms down; (2) swing sideward, palms up, forcing shoulders back and chest out; (3) return to front position; (4) return to thrust. (Chest, shoulders.) Variation: At 2 swing arms upward.

Arms Sideward Upward—vertical, parallel, palms facing; (1) Bend trunk to right side; (2) recover starting position; (3) bend trunk to left; (4) recover. (Trunk, side and back muscles.) Variations: Bend trunk 30° forward and backward on 1 and 3. Bend trunk forward and circle right, back, left and forward.

Hands on Hips—thumbs to rear, tips of fingers on point of hip; (1) Quarter bend knees, spreading them and lowering trunk in its erect position as far as possible without raising heels; (2) recover. (Leg muscles and joints, balance.) Variations: Half bend—heels off floor; or full bend—sitting on heels, in all cases body erect.

Hands on Shoulders—tips of fingers touching shoulder, elbows to sides and pressed back, upper arm horizontal; (1) Rise on toes, stretching body upward; at same time extend arms to side horizontal, palms up; (2) recover. (Toes, calves, arms.) Variations: Extend arms forward, or upward, or to the three positions in rotation.

Hands on Hips—(1) Bend neck forward, chin in, stretching back of neck; (2) recover; (3) bend neck backward; (4) recover. Variations: Bend neck to sides or bend forward and circle head right, back, left, forward.

Arms Sideward Upward—lock thumbs, palms to front; (1) Full bend trunk forward, touching floor, knees straight; (2) recover; (3) bend trunk backward; (4) recover. (Stomach and back muscles.) Variations: Spread feet about 18 in. and swing hands down and back between legs, or twist trunk as it bends forward and swing arms to side of legs and backward.

Hop to Side Straddle—feet spread about 24 in., landing on toes and raising arms sideward upward; (2) recover attention on toes. Execute in fast cadence, loosening up all muscles of body.

Lunge forward with right foot 30 to 40 in., right knee bent, raising arms to side horizontal, palms up, upper body erect; (2) bend trunk forward, clasping right knee with both arms; (3) recover first position; (4) recover attention. Repeat lunging with left foot. (General exercise, arms, trunk and legs.) Variations: Lunge to sides and on 2 twist as well as bend the trunk so as to clasp the knee.

Bend to squatting position, hands on floor between the feet, knees spread; (2) extend legs backward, feet together, toes on floor, body straight, supported only on toes and straight arms; (3) recover squatting position; (4) recover attention. (General exercise, arms, shoulders, trunk, back, legs.) Variations: Extend one leg back at a time, alternating; or both legs back and at (3) spread feet 30 to 40 in., at (4) bring feet together; (5) recover squatting position; (6) recover attention.

Lie on Back—hands at sides, palms on floor; (1) Raise right leg to vertical, knee straight, toes pointed upward; (2) lower; (3)

raise left leg; (4) lower; (5) raise both legs; (6) lower. (Trunk.)

Sitting Position—arms to thrust, knees straight. Rowing exercise: (1) Bend trunk forward, extending arms to touch toes; (2) recover erect sitting position bringing arms to thrust with force. (Trunk and chest.)

Leap in air 8 or 10 in. (1) toes point down and back, knees straight, legs together, throwing arms upward, sideward and back, head back, looking at ceiling and arching back in midair, all in one count; (2) return to position of attention on toes. (General exercise all parts.)

Hands on Hips—(1) Swing right leg to front horizontal, bending trunk forward and extending left hand to touch right toe, rising on left toe; (2) recover; (3) same with left leg and right arm; (4) recover. (Loosening exercise, leg and trunk.)

Breathing Exercise—(1) Inhale slowly, rising on toes, raising arms forward upward, filling the lungs, raising chest and stretching the whole body upward; (2) exhale rapidly, bringing arms down and back to sides and resume attention. Repeat 5 to 10 times.

(E. L. K)

PHYSICAL RESOURCES. Though the term "physical" or "natural" resources has no precise definition, it may be taken to designate those things, inert substances, living organisms and effective combinations or products of natural forces, which men utilize to promote their material well-being.

An analytical classification of natural resources might rest on any one of several bases. The historical method might be followed, since it is known that primitive men first made use of vegetable materials, later domesticated animals and finally arrived, at a relatively recent time, at a state of civilization in which the extensive use of minerals is the most important characteristic. As this coincides with fundamental distinctions as to the nature of the resources themselves, it will, in general, be followed here. Another basis of classification might be the human needs which they serve, but such a classification would be confusing, since both vegetable and animal products are used for such diverse purposes as food and clothing, while mineral products as well as the other two are used for shelter. Still another basis of classification might be a division into those resources which men use as a source of energy, and those which are used in connection with its application or production. This classification is also partly followed.

Underlying these considerations is the more fundamental view of natural resources as the principal things that are utilized in the satisfaction of human wants. The most fundamental of these are air, water, food and sunlight. Shelter, clothing and a variety of simple tools are more complex wants and illustrate the kinetic aspect of human needs. The horses, cattle, dogs and other animals of to-day do not (broadly speaking) want anything beyond what the same animals wanted in 5000 B C, while the wants of men have greatly increased and diversified during the same period Much of the material that is utilized to-day owes its usefulness to the way in which it satisfies mental and spiritual rather than purely physical needs. Raw materials therefore pass through repeated transformations and modifications before they serve their final end. A symphony concert, heard over the radio, is related in a remote and complex way to the lumps of ore and fragments of wood which are the basic components of the musical instruments. Though natural resources will be here discussed in their material aspects they are also involved, in a most important and essential way, in the mental and spiritual life of men.

Most of the energy-imparting resources have their basal origin in the radiant energy from the sun. The animal products which men utilize, have been derived by metabolism from vegetable life, and this is in turn the product of the action of living cells upon inert substance, resulting from the energy input of the sunlight. E. E. Slosson has estimated that the heat received by radiation from the sun in a growing season in the latitude of Washington, D.C., amounts per acre to more than would be produced by burning over 200 tons of coal, while the heat value of the corn (maize) grown on an acre in a season amounts to less than that in half a ton of coal. The energy content of coal is ultimately derived from sunlight, and evidence strongly indicates that petroleum and natural gas are decomposition products derived from organic material. Their energy content is derived from the same source.

Water is, similarly, another of the great natural resources, since it is an essential to the life of both plants and animals. The amount of it present in the atmosphere determines, to a large degree, the character of the vegetable and animal life in a given area, while in the descent over the land surface it may be utilized as a perpetual source of power.

The atmosphere is almost never thought of as a natural resource, because it is everywhere present and freely available to all. Yet its oxygen content is essential to all animal life and to the combustion by which power is derived from the hydrocarbons, and its rather small content of carbon dioxide forms, with water and sunlight, the basic components of vegetable life. It also furnishes the mechanism by which water is enabled to maintain its cycle of distribution. Its vital importance as a cooling agent to the human body, considered as a machine, and upon human health, has only become fully recognized within the present century.

Soil, as the rather complex superficial layer which covers the earth's surface is termed, is also an important basic natural resource. It furnishes not only the mineral constituents necessary for plant growth but also the physical conditions that are equally essential. The nature of the soil of a region affects, to a considerable degree, the civilization which may there develop. The character of the soil, in turn, is profoundly affected by climate. Vegetation, forests and animal life are in turn affected by soil and climate, so that these natural resources are complexly interrelated.

The inert natural resources, which may be thought of as static rather than kinetic, may be subdivided into those that are sources of energy, and those which are utilized in other ways. One significant difference is that the first group are destroyed in use, while the others are permanent, to a varying degree Most of the gold that has been produced is still available, while most of the coal that has been produced has been completely destroyed. The lead in storage batteries, on the other hand, is almost completely salvaged and re-used, while that used in paint is almost completely lost. The steadily growing use of natural resources such as these and the fact that the quantity of each now available by the present methods of production has, in every case, some limit and in many cases one that, at the present rate of increasing consumption, is near enough in the future to be a source of real concern, make it appropriate to include in an article on natural resources a discussion of possible substitutes.

The discussion given below is divided as follows: (1) energy group; (2) metallic and non-metallic group; (3) precious metals group; (4) rare metals group; (5) substitutes for natural resources. (T. T. R)

ENERGY GROUP

This classification here includes Animal Life, Vegetation, Soils, Water, Fisheries, Forests, Natural Gas, Coal and Petroleum A discussion of food supply is given in the article FOOD SUPPLY OF THE WORLD Under the article SUN there is a description of this form of energy considered as a natural resource

I. ANIMAL LIFE

The ability of animal life to perpetuate itself and in addition to supply man with a large proportion of his necessities and comforts has materially aided human progress Besides being one of the most interesting and valuable of the world's resources, animals have impressed a record of their own on the pages of history Ancient inscriptions portray the hunt, the feeding of live stock, milking scenes and the slaughter of domestic animals for food.

Man's migrations over the globe and his ability to sustain himself under diverse and adverse conditions have depended largely on animal life With the camel or horse, man can live in the desert. With sheep he can establish himself in regions of high elevation or sparse vegetation With the presence of wild life and a few dogs he can inhabit the frigid zones. Under the more

favourable conditions prevailing in temperate climates, man has built up extensive industries, producing meats, hides, wool, milk and other animal products in commercial quantities. For such purposes he has developed breeds and types especially adapted for his own use or for the demands of his markets.

It is clear, therefore, that the greatest usefulness of animal life to man depends on his wisdom and ability in regulating the number and kind of animals under his control so that they may best serve his needs. With the steady increase in human population, there has been a progressive tendency toward the raising of animals for definite human needs rather than depending on wild life. In recent years this trend has also included the breeding and raising of fur-bearing animals.

Live-Stock Production.—In the age-old struggle for the survival of the fittest, certain types of animal life have proved to be especially well adapted to man's requirements. These he has preserved, improved and protected until their production has become a major part of the world's agriculture. It is important to bear in mind that crop production and stock raising are closely allied enterprises, inasmuch as animals consume most crops that are not utilized by man directly. Moreover, land that is too rough for cultivation may support vast herds of cattle, sheep and goats. (See *Vegetation* below.) Thus live stock serves as a useful balance wheel in the mechanism of human nutrition. Famine rarely occurs in countries where live stock is abundant.

As in the production of other commodities, however, a great number of economic factors are involved. These influence the extent of animal breeding and feeding operations, thus determining the number of animals produced and their age and condition when marketed. As a consequence, animal life as a natural resource is the basis for an industry which, though of great magnitude, varies in extent from year to year, depending on supply and demand. Animal life is an elastic resource, responding closely to the demands made upon it. In most countries the principal domestic animals are counted or estimated periodically and this information serves as a guide for breeding and feeding operations.

Extent of Live-Stock Industry.—As a world resource, cattle exceed all other domestic animals in number and value, aggregating about 629,000,000 head, according to current estimates. This term includes all bovine animals, whether kept for beef production, dairy purposes or as draft animals or beasts of burden. In some countries, notably India, buffaloes are included in cattle estimates. Of the world total, Asia possesses about two-fifths, Europe about one-fifth, with South America, North America, Africa and Oceania following in the order given. Oceania includes Australia and New Zealand. Sheep are the next most numerous domestic animals of economic importance. The world's supply is estimated at about 593,000,000. Of this number Europe has nearly a third, Asia about a fifth and Oceania slightly less than a fifth. South America, North America and Africa follow.

Swine, though much fewer in number than either cattle or sheep, are noteworthy as a food resource owing to their fecundity and early maturity. The adaptability of pork for curing is also worthy of mention as it permits storage and long shipments without refrigeration. Throughout the world, swine are estimated to number about 255,000,000, of which Asia, Europe and North America, respectively, have the largest supply. On the other continents, the swine industry is relatively undeveloped. Though the world's animal resources include a great variety of other stock utilized for food, work and sundry purposes there is a dearth of dependable information regarding their numbers. Even in the case of cattle, sheep and swine, which have just been mentioned as of outstanding prominence, numbers alone give scarcely a true picture of their value to the populations of the various countries. The improved bovine animal, as found in North and South America and in the British Isles, where much attention has been given to breeding for beef production, is vastly different from the beast of burden types in India or Mongolia.

Types of sheep vary greatly, depending on the relative demand for their wool and meat. Similarly, man's influence on animal life has resulted in swine that excel in bacon production or a high yield of lard, depending on the breed selected. Differences in types of animals extend to horses, goats, poultry and pet stock. These differences have been brought about through systematic breeding for a long term of years, giving rise to the establishment of recognized breeds embodying the conformation and other qualities sought. Record associations for the various breeds have served to maintain uniform standards and otherwise to aid in development and improvement. Live-stock shows and expositions at which prizes are offered for animals of superior merit likewise have been influential in stimulating breeders to their best efforts. In the case of food animals especially man's skill in the selection of breeding stock has greatly increased the utility value of his herds and flocks. Whereas the dressed carcass of an ordinary hog weighs, usually, between 65 and 75% of its live weight, the proportion is more than 80% in the case of well-bred, well-managed swine. Moreover, good breeding tends to result in earlier maturity so that animals may be marketed profitably at younger ages, with a resulting saving in feed, labour and other expenses. So highly has this feature of stock raising developed that it is not unusual for a litter of pigs from one sow to weigh a ton or more at six months of age. Improved breeding has numerous practical benefits in the raising of other kinds of live stock. Consequently there is keen competition among progressive stock owners throughout the world in obtaining choice breeding animals.

Inasmuch as the population of the world is increasing steadily, much study has been given the conservation of animal life in order that it may yield more meat and live stock products per unit of area. In regions where land values have increased there is need also for economic reasons to reduce losses and to seek greater economy in production. As a consequence public officials and stockmen have engaged in co-operative endeavours to combat animal diseases and parasites and to stop the ravages of predatory animals. Improved housing and equipment likewise have reduced losses from exposure and the mortality among young animals.

Veterinary Medicine and Surgery.—Beginning originally in France as a means of saving horses injured in war, there has developed in the more important live-stock countries a system of medical service for animals. The science of veterinary medicine and surgery, though designed chiefly to conserve animal life, has made many direct contributions to human welfare. Knowledge of animal anatomy is the basis for the official inspection of meat and meat food products, and the veterinary inspection of dairy cows safeguards the milk supplies of progressive municipalities. With veterinary medicine there has developed also research into problems affecting the health and well-being of man and animals alike. The discovery, by veterinarians, of means to eradicate tick fever from cattle led shortly afterwards to success in combating malaria and yellow fever in man. Knowledge concerning tuberculosis among animals is leading similarly to a reduced incidence of this scourge in the human population, especially among children.

In the light of such information, any statistical measure of the world's animal resources and their usefulness to man in the form of food and clothing must necessarily be incomplete. There can be no accurate appraisement of the service rendered by man's noble friend, the horse, nor by his faithful companion and guarding sentry, the dog. And in the frozen wastes of the globe the oily flesh of animals constitutes the very home fires which maintain human existence. The lower animals are resources which adapt themselves to man's changing needs, and if wisely managed give promise of abundance for many generations to come.

(J. R. Mr.)

II. VEGETATION

If the great physiographic divisions are excempted, the earth's surface is marked more distinctly by vegetation cover than by any other feature. This fact early attracted man to the study of vegetation as distinguished from the study of the individual plant. Primitive man recognized the plant cover not only as a source of sustenance and protection, but also as a guide in his hunting and planting his food crops. Studies in vegetation and its relation to the factors of the environment began very early.

In the recognition of a plant community (a term used in a general sense to include all groups, large and small) the following criteria may be employed: Physiognomy, or the general appear-

ance, historically stands in first place, followed closely by floristic composition which has formed the basis of the science of floristic plant geography. Succession seeks to determine whether the vegetation has reached its final stage, complete adjustment to environment. The study of Habitat (*see* PLANTS: *Distribution and Ecology*) seeks to evaluate climate, soil and biotic factors.

The terrestrial vegetation of the world may be classified into the following great plant types: *Forest, Grassland* and *Desert.* The forests of the world may be divided into seven great formation groups covering a world area of about 22,000,000 square miles. Most of this area is valuable timber land, and about 14,000,000 sq.m. are capable of being converted into crop-producing land, of which about 6,000,000 are suitable for warm-weather crops, and 8,000,000 suitable for cool-weather crops. About 3,000,000 sq.m. of forest land are suitable for grazing only. The grasslands of the world are divided into seven great formation groups covering 13,000,000 sq.m. of valuable grazing land. Of this area 3,500,000 sq.m. are suitable for the production of cool-weather crops such as wheat, rye and oats; while 6,800,000 sq.m. are suitable for warm-weather crops such as sorghum and cotton; and 2,700,000 sq.m. are suitable for grazing only. The deserts may be divided into five great formation groups covering a world area of 17,000,000 sq.m., valuable chiefly as grazing land of low carrying capacity and, where water is available, for irrigation farming. The world contains about 26,000,000 sq.m. of land suitable for grazing; about 12,800,000 sq.m. of land capable of producing warm-weather crops, and about 11,500,000 sq.m. capable of producing cool-weather crops. Allowing no waste land it would limit the production area of the world to less than 25,000,000 square miles.

Forests.—*Tropical Rain Forest* is a luxuriant, evergreen forest with trees of unequal size and height and of varying age forming a dense canopy of thick, leathery leaves, and composed chiefly of Leguminosae, Lauraceae, Myrtaceae, Moraceae and Dipterocarpaceae—a true climax forest with trees of all ages and a mixture of many species. Temperature is uniformly high, air damp, and rainfall 60 to 200 in. per year. Soil is greyish or reddish-brown, poor in humus and containing a large amount of hydrolyzed iron and alumina. Animal life is abundant but chiefly arboreal. Primitive man has lived for the most part at the edge of this forest, and civilized man has utilized natural products such as rubber, gum, wood and bark. Cultivated crops are chiefly tropical such as rubber, sugar cane, cacao and tropical fruits, vegetables and fibre plants, though temperate ones can be grown. This forest covers 3,800,000 sq.m., in Africa, South America and the East Indies.

Temperate Rain Forest is even more luxuriant and varied than the tropical rain forest. It is a many-storied forest, rich in mosses, tree ferns and vines. It consists of the southern conifers such as *Podocarpus* and *Araucaria,* as well as *Ficus, Olea, Juniperus* and *Nothofagus.* The temperature is moderate and the rainfall 40 to 80 inches per year. Under cultivation it will produce temperate cereals and fruits. This forest occupies about 550,000 sq.m., chiefly in the highlands of Central Africa, South America, south-eastern Asia, East Indies and Oceania.

Deciduous Forest is characterized by a dense foliage of thin, grass-green leaves which fall and leave bare branches with heavy bark and scale-covered buds during a long, cold rest period. Oak, birch, beech, maple and ash dominate this forest. There are two distinct climatic seasons: a warm, moist season or growth period, and a cold, moist season, or rest period. Precipitation varies from 30 to 70 in. The soils are either light coloured podsols or grey forest soils. Under natural conditions this forest supports a fauna and fruits and nuts for primitive man. It produced much of the wood and hardwood lumber, and has given way to fields of temperate crops and deciduous fruits. There are three great areas of this forest: Eastern United States, western Europe, and eastern Asia. The total area is about 6,500,000 square miles.

Coniferous Forest presents a uniform stand of similar evergreen trees, and consists chiefly of pine, spruce and fir. The winter climate is rigorous; rainfall varies from 15 to 100 in. annually; the soil is young but the land is of little agricultural value. This forest is the source of much of the lumber used in commerce. It extends across America and Eurasia south of the tundra and pushes down over the highland as far as north Africa and Mexico. It covers about 7,600,000 sq.m. of which 5,500,000 are true forest, and 2,100,000 are woodlands. About 1,000,000 sq.m. are suitable for grazing, 40,000 sq.m. suitable for cool-weather crops and 30,000 sq.m. suitable for warm-weather crops.

Dry Forests are deciduous forests in the tropics and are often called monsoon forests. Leafless during the dry period, they have no cold rest period as does the deciduous forest of the temperate regions. These forests are usually composed of leguminous trees. The temperature is high and rainfall 30 to 40 in. during the growth period. Teak and quebracho are valuable forests of this type. The soil produces good crops of warm-weather cereals, vegetables and fruits. This forest is chiefly in Africa, South America, Australia, south-eastern Asia and Oceania, and occupies about 2,000,000 square miles.

Thorn Forest is composed of small thorn trees, vines and succulents. The trees are leafless during the long drought periods and are found in tropical or sub-tropical regions where the annual rainfall is from 10 to 20 in. Legumes, cacti, euphorbias and lilies are important. This area is unfavourable to primitive man and to animals, but produces gums, fruits, rubber and tanbark. It has no value agriculturally without irrigation, and covers about 330,000 sq.m. in Africa, South America, Mexico, Australia and the dryer portions of Asia.

Sclerophyll Brushland is a forest of small trees or a brushland with evergreen sclerophylls ranging from minute ericas to tree-like proteas, oaks and cherries. Botanically it is extremely variable. The temperature seldom falls below 26° F; rainfall is from 20 to 35 in. annually, and there is a drought period of three to five months. It is an unfavourable habitat for man and animals under natural conditions, but under cultivation it is most favourable for the production of citrus and deciduous fruits and cereals, alfalfa and vegetables. This forest covers about 1,100,000 sq.m. chiefly in the Mediterranean region, Cape Province, south-western Australia, central Chile and California.

Grasslands.—In the *High Grass Savanna* the luxuriant grasses range from 5 to 12 ft. high and consist chiefly of species of *Andropogon* and *Pennisetum.* The luxuriant growth period is followed by a drought during which the grasses are burned. Annual rainfall ranges from 25 to 75 in. The area varies each year from a grassy swamp to a dry desert. The natural production is not great, although the larger animals live here, and rubber, oils and ivory are produced. Under cultivation warm-weather crops of great variety can be produced. This savanna covers about 2,800,000 sq.m. in Africa, south Asia and South America.

The *Tall Grass Savanna,* known as Low Veld or Tree Steppe, consists of grasses from three to five ft. high with trees 10 to 30 ft. high scattered through. The grasses are chiefly andropogons and the trees legumes. The temperature is tropical or sub-tropical with rainfall of 30 to 80 in. It is excellent grazing land. It is a favourable home for primitive man and for civilized man, with rich agricultural lands producing cattle and cool or warm-weather cereals and vegetables. It covers a world area of about 3,900,000 sq.m. in South America, Africa, India and Australia.

Tall Grass, the prairie of North America, the pampas of South America, and the high veld of South Africa, are luxuriant, pure grasslands of blue-stems (*Andropogon*), spear-grass (*Stipa*) and wheat-grass (*Agropyron*). The climate is temperate; rainfall is from 20 to 40 in. annually, and the soil is unusually deep and rich, forming a true *chernozyóm* in the dryer portion. There is a short drought rest period, followed by a long, cold rest period. It is excellent grazing land; it supported great herds of wild game, and later cattle and horses, which have given way to its utilization as the richest grain fields of the world. It occupies about 1,580,000 sq.m. in the United States (chiefly east of the 100th meridian), Uruguay and the Argentine, south Russia and Siberia, Rumania and Hungary, South Africa and Australia.

Short Grass is only a few inches high, occurring in a temperate region with rainfall of 15 to 30 in., with a long drought and a cold rest period. The grama, buffalo-grass, spear-grass and needle-grass are valuable for grazing. The better portion of this land is used for dry farming. The soil is dark brown with an accumulation of

carbonate at a depth of 8 in. to 3 ft. below the surface. The world area of this grassland is about 1,200,000 sq.m., chiefly in North America, South America, Africa and Russia.

Desert Grass Savanna, sometimes called Orchard or Thornbush Steppe, consists of a carpet of short or low bushy grasses, including grama-grass, buffalo-grass, wire-grasses, and scattered small trees, with leguminous and other shrubs. Rainfall is from 10 to 20 in., and there is a long, hot drought period. About 2,300,000 sq.m. are occupied by this type of grassland; it is valuable as grazing land of low-carrying capacity. About 140,000 sq.m. are valuable agriculturally, producing cotton, sorghums and peanuts.

Mountain Grassland occurs on the high mountains in the tropics. The climate is temperate with 40 to 60 in. of rain. The grasses are chiefly species of blue-stem (*Andropogon*) (*Eragrostis*) and dropseed-grass (*Sporobolus*). It is generally valuable grazing land, and under cultivation produces temperate crops as well as bananas and coffee and is similar to the Temperate Rain Forest. The world area is about 790,000 square miles.

Marsh Grass occurs in the great swamp areas and consists of coarse grasses. It supports a fauna valuable for meat, furs and ivory, but without drainage is of no agricultural value. The world area is about 100,000 square miles.

Desert Shrub and Desert Grass consists of a sparse cover of low, woody or fleshy plants with desert grasses between. Botanical composition varies greatly, but legumes, composites, cacti and euphorbias are prominent. Rainfall varies from 5 to 20 in. annually. About 10,000,000 sq.m. of this type are valuable as grazing land of low-carrying capacity, but valueless for crop production without irrigation.

Salt Desert Shrub occupies the low, undrained saline basins in all desert regions. It is valuable for grazing land, but for agriculture it must be leached of salt. The world area is about 30,000 square miles.

Desert in the true sense is seldom found, but at least during much of the year many areas seem lifeless. The flora is abundant in species if not in individual, and the plants are adapted to the extremes of drought and uncertain moisture supply. The world area in Africa, Asia, South America and Australia is about 2,400,000 sq.m. and is of little value.

Tundra (including *Alpine Meadow*) shows mixed botanical composition. The growth period is short with a long, cold rest period. In summer the temperature rises gradually to 60° or 65° F, and during the continuously dark winters the temperature falls to 40° F below zero. This area is valuable for grazing land, though not especially productive. The circumpolar world area is about 4,400,000 square miles. (H. L. Sh.)

III. SOIL

In an inventory of the world's resources it is as important to consider the soil in its crop-producing capacity as it is to estimate the reserves of coal, copper and oil, substances more commonly thought of in this connection. All of our food, our clothing and many of our utensils, implements and ornaments come either directly or indirectly from the land. (*See* Food Supply of the World.)

The crop producing capacity of the soil is, however, a natural resource in a somewhat different way from that represented by coal or oil. These substances have a definite entity and can be estimated in tons and gallons. Once depleted they are manifestly gone. The soil, on the other hand, is a resource because of its ability to produce crop-plants. This capacity varies, it may be much reduced and then be definitely rebuilt.

While an accurate and complete tabulation of the soil resources of the world is impossible, the table in the next column gives some idea of the situation. (*See* Soil; Agriculture.)

Besides indicating the magnitude of the soil resources in acres, the table shows the proportion of the landed area available for crop-plants. This in connection with the population has an important bearing on the possible agricultural and silvicultural independence of each country. Such countries as Argentina, Canada, Australia and Russia can support much larger populations. Their forest resources in terms of population are also great.

Table Showing the Approximate Areas of Ploughed and Forest Lands of Some of the Important Countries of the World

Country	Ploughed lands			Forest lands		
	Acres in millions	% of land area	Acres per person	Acres in millions	% of land area	Acres per person
Argentine Republic	52·74*	7·1	5·1	264·00	35·8	25·5
Commonwealth of Australia	17·77†	·9	2·9	90·20	4·7	14·6

Great Britain	13·56	23·8	·3	2·74	4·8	·06
United States	391·46	20·1	3·2	550·00	28·3	4·5
Soviet Russia (U.S.S.R.)	107·17§	2·3	1·1	1,984·55	42·8	20·9

*Possible agricultural area estimated at 250 million acres.
†Cropped area will ultimately be much greater.
‡Possible agricultural area estimated at 300 million acres.
§Possible agricultural area estimated at 700 million acres.

With our rapidly increasing world population two major soil problems present themselves, *first,* the possibility of increasing the area of lands growing crops other than forests, and *second,* methods of preventing soil depletion and consequent crop decrease. The utilization of virgin and well watered grass lands and the reduction of our forest areas have met the first problem in times past. Unfortunately soils have often been deforested and put under cultivation when they should have been left with their forest cover.

The reclamation of swamps and the better drainage of crop-bearing lands have increased the area and effectiveness of the cultivable soils. (*See* Drainage; Reclamation of Land.)

The utilization of arid and semi-arid lands is particularly promising in certain countries. Such soils, developed under low rainfall, are potentially fertile. Thousands of acres of arable and very highly productive lands will ultimately be added to that now available for crop production through irrigation (*q.v.*).

Another important means of utilizing semi-arid soils is by dry-land farming. (*See* Agriculture.) By proper methods of cultivation, moisture is conserved in the soil and carried from one season to the next. Farming operations thus become possible in areas where the annual rainfall is as low as 20 inches.

The second major soil problem relates to the maintenance of soil fertility. Land can not be cropped without certain losses taking place. These losses are four in number: *first,* erosion or the removal of the surface soil, the most fertile portion, by water or wind; *second,* the loss of constituents by the drainage of water through the soil, called leaching; *third,* the removal of nutrients by plants; and *fourth,* the loss of organic matter as a result of bio-chemical oxidation and the liberation of carbon dioxide.

Water erosion may be controlled by small dams, by terraces, and by the use of sod crops. In spite of such possibilities, however, thousands of tons of fertile soil are swept annually into our rivers. In many cases this is the major cause of soil depletion and is closely correlated with deforestation and flood devastations.

The losses through drainage, crop removal and organic oxidation are susceptible of but little control. Farming operations, even the most careful, encourage rather than check such depletions.

The major features of soil fertility maintenance may be very simply set forth if it is taken for granted that the soil drainage is good, that tillage is adequate, that erosion is under control, and that a suitable crop rotation, if possible, is utilized. Under such conditions the problem is to add certain constituents in such amounts and proportions as at least partially to off-set the inevitable losses. At the same time the physiological balance of the plant nutrients should be maintained as nearly as possible.

While plants require ten nutrient elements for their normal growth and probably several more besides, ordinarily only four are likely to become especially critical, namely nitrogen, potassium, calcium and phosphorus. Sulphur also may be a limiting

factor particularly for such crops as alfalfa and sweet clover.

The nitrogen losses may be met by applying farm manure, turning under crop-residues and by utilizing, either as a crop in the rotation or as a green manure, certain legumes. Commercial nitrogen may be resorted to, although it is generally used to stimulate the crop directly rather than to reduce the drain on the soil nitrogen. Obviously the methods utilized in maintaining the soil nitrogen automatically add organic matter as well. As this material decays and humus is formed a definite ratio is established between the organic matter and the nitrogen. The nitrogen is always in the minimum and apparently controls the amount of humus that finally is present in the soil. The advantage of legumes as green manures over non-legumes is quite apparent, since they obtain nitrogen from the air and are especially rich in this constituent. The soil organic matter besides carrying nitrogen is a source of energy for various bio-chemical transformations and encourages a suitable physical condition of the soil.

The presence of this decaying organic matter tends to make available to plants certain soil constituents, especially potassium. Therefore it is often unnecessary to add a potassium fertilizer to a soil rich in this element if the organic matter is properly maintained and is actively decomposing.

Many soils are low in active calcium and as a consequence become acid. This deficiency also develops other conditions that may be detrimental to some plants but by no means to all. Liming, therefore, must be resorted to for certain crops and is thus an important feature in the maintenance of soil fertility the world over. (*See* FERTILIZERS.) The lime not only reduces the soil acidity but also adjusts other physiological soil conditions.

Phosphorus exists in the soil in small amounts and is often very slowly available to plants. In fact it is so slightly soluble as to be lost but sparingly, if at all, in the drainage water. The only way of dealing with this element is by direct addition of phosphorus fertilizers (*q.v.*).

As the losses of soil constituents increase, the necessity becomes greater for commercial fertilizers.

IV. WATER

Water is probably the natural resource that is most essential to man's existence on the earth. It furnishes him food and drink, means of sanitation and transportation and in large measure the power necessary for his use of other natural resources.

Surface Water.—Run-off is directly the result of precipitation, but the rapidity with which run-off follows precipitation depends upon various conditions, most conspicuously the snow storage. In tropical and subtropical lands the sequence is rapid, but in extreme northern and southern areas it may be delayed several months. The areas from which run-off is supplied mainly by melting snow embrace in general all lands north of the Arctic Circle and all areas that rise above an elevation of about 5,000 ft. in the latitude of the northern United States and central Europe, and above 12,000 to 15,000 ft. in the tropics. In other areas run-off occurs most frequently during the rainy season. If the rainfall is fairly uniform throughout the year as it is in the eastern United States and most of western Europe, the distribution of run-off is also nearly uniform, but there is a considerable reduction during the summer, due to heavier evaporation. Areas in subtropical and warm temperate lands receive precipitation during a definite rainy season, which may not exceed half the year, and the run-off from such areas is, therefore, likely to be variable. On the other hand, streams that rise in areas having a permeable soil and subsoil or are underlain by cavernous rocks are likely to have relatively well maintained run-off. Lakes which cover a considerable part of a drainage basin tend to regularize run-off. Streams draining areas in which there are two or more of these type conditions have a composite run-off. Good examples are the Great Lakes of North America and the lakes at the head of the White Nile in equatorial Africa.

The utility of any stream for power, irrigation or municipal supply, depends in large measure upon the adaptability of its run-off to the demand. Storage must ordinarily be provided to assist in this adaptation. Natural sites available for use as storage reservoirs may contribute largely to the value of the water resources of a drainage basin. Areas that were covered during the glacial period by continental ice sheets or by extensive alpine glaciers generally abound in lakes, which in their natural condition regulate run-off in some degree, and some of these lakes may be converted into reservoirs of large capacity. High rates of run-off and attendant possibilities of power and irrigation development are generally associated with mountainous areas, such as the Sierra Nevada and Cascade Range, in western North America, the central Andes of South America, the Alps and Caucasus in Europe and the Himalayas in Asia.

Ground Water.—Practically all vegetable life depends for sustenance upon underground water. It has been estimated that 50% of the population of the United States depends directly upon wells for its water supply and the proportion for the world is no doubt nearly, or quite as great. A large part of the water used for irrigation is drawn from the ground, which contains water in immense quantities. The practicable use of this water is measured not by its total volume but rather by the extent to which it may be replaced by precipitation. In many areas the water table has been progressively lowered by excessive pumping. In some places the rate of recharge of the underground water from surface streams may be increased to offset the lowering of the water table, but large drafts on the supply inevitably reduce it. Seepage due to the excessive use of water for irrigation generally finds its way into the ground and in many places may be re-used after it is discharged from springs or recovered by pumping.

Water-power.—The developed water-power of the world, according to estimates made by the U.S. Geological Survey, was about 23,000,000 h.p. in 1920, 29,000,000 h.p. at the end of 1923 and 33,000,000 h.p. at the end of 1926, an increase of 43% in six years.

Summary of Developed Water-power of the World in 1926, and Potential Water-power at Ordinary Low Water in Horse-power

	Developed	Potential
North America	17,635,000	65,800,000
South America	751,200	54,100,000
Europe	13,100,000	58,100,000
Asia	2,068,000	69,200,000
Africa	13,680	190,950,000
Oceania	242,500	16,650,000
Total	33,810,000	454,800,000

The estimates given above are based on data of widely varying completeness and accuracy, but they afford a general idea of the water-power resources of the world. For Asia, Africa and South America, where great areas are practically unexplored, it has been necessary to rely largely on studies of precipitation and topography. It appears that the potential water-powers of four of the continents are approximately equal, that Africa's quota is equal to that of any other three, and that Oceania, including Australia, possesses a negligible quantity. Africa is essentially a great plateau on which the streams are large and from which they fall rather abruptly to the sea. Tropical Africa, particularly the Congo, comprises the largest land area within the belt of the equatorial rains, and this fact taken in connection with the characteristic topography of the continent, gives it by far the greatest concentration of potential water-power on the globe. Asia comprises vast elevated areas, including the highest mountains and plateaux, but in northern, western and central Asia the precipitation is low, and in its southern and eastern parts the rainfall is irregularly distributed through the year. The water power resources of Asia are therefore hardly greater than those of North America.

Irrigation.—Nearly one-third of the earth's surface receives only 10 in. of rain or less annually, and for another third the annual rainfall is between 10 and 20 inches. On the area receiving

less than 10 in. and on much of that receiving up to 20 in., irrigation is generally essential to the production of a profitable crop. The earliest civilization of which we have any knowledge was developed by means of irrigated agriculture. Not until near the Christian era did the world dominion and leadership in art and culture pass to nations inhabiting other than great irrigated lowlands such as Egypt and Mesopotamia. With the general decay of civilization during the dark ages, irrigation systems were neglected and some were entirely destroyed by invading armies. Egypt, protected by the sea and the desert, suffered relatively little. Mesopotamia, exposed to the full fury of successive surges of Mongolian nomads, received blows from which it has never recovered. With the advent of the Renaissance and the gradual growth of modern civilization, the centre of civilization gradually shifted to the more humid parts of northern Europe and eastern North America, and artificial moisture became a less important factor in the growing of the world food supply.

After 1875 new influences in world affairs gave a decided impetus to irrigation development. Railroad construction has opened up vast areas of arid and semi-arid lands requiring irrigation to bring them to a high degree of crop production. Construction equipment and methods have been greatly improved. Projects are now feasible which, a half century ago, would have been entirely impracticable. Dams are projected and under construction of a height and size undreamed of a few decades ago. Improved standards of living have increased the demand for certain products of irrigated lands such as citrus and deciduous fruits, and increased transportation facilities have made possible their widespread distribution. As a result, the irrigated areas in the newly developed countries of the Western Hemisphere have been increasing rapidly. The population of India, China and other lands of ancient civilization has been very largely limited by the area of tillable land, and this in turn by the supply of water available for irrigation. The very considerable growth during recent years in the population of India has been due in large measure to the effectiveness of the irrigation works constructed by the Government. Probably one-fourth of the population of the globe is now primarily dependent for food on the products of irrigated land.

The irrigated area of the world by countries in 1926 has been estimated by the U.S. Bureau of Reclamation as practically 200,000,000 ac., made up by continents as follows: North America, 26,834,000 ac.; South America, 6,613,000 ac.; Europe, 14,798,000 ac.; Asia, 140,760,000 ac.; Africa, 10,310,000 ac.; Oceania, 1,270,000 ac.; grand total 200,585,000 acres. (F. F. H.)

V. FISHERIES

The important fisheries of the world are found for the most part within the north temperate zone, chiefly between the 40th and 60th parallels of north latitude. In this region conditions are especially favourable to fish life, including large continental shelves with relatively shallow water and extensive coastal indentations, richly supplied with materials from the massed land areas of the region to support an abundant aquatic flora and fauna. The herrings, of which there are some 150 species, represent the most important family of fishes. The species are widely distributed in fresh and salt water and contribute a greater yield than any other family of fishes. They supply the raw materials for the highly important sardine industries of Norway, France, Spain, Portugal and the United States, the extensive herring curing industries of northern Europe and North America, extensive fish meal, fertilizer and oil industries of Norway, United States, Canada and Japan, as well as being widely used for food in the fresh state wherever they are found. As they feed on microscopic plant and animal forms, they are especially important as converters of plankton organisms at one step into food for man.

The gadoid fishes which include the cod, haddock, hake and pollock also rank high in their contribution to man's needs. The annual catch of cod along the Atlantic coast of North America exceeds 1,000,000,000 pounds. These are white-meated fishes, and the fat is stored in the livers, the basis for the cod-liver oil industry. Next in importance are the salmons, noted for their exceptional food properties, size, beauty and gameness. The family includes not only the salmons but the white fishes, the ciscoes or lake herring and the trouts. The most important members are the five species of salmons native to the North Pacific, entering the tributary rivers in North America and Asia to spawn. The annual catch amounts to about 1,000,000,000 lb. a year and is the basis for the important salmon canning and curing industry.

The mackerels, of which there are about 60 species, are widely distributed and highly prized for food in the areas where they are found in abundance. Included in this family are the highly prized tunas, the true mackerels of the north Atlantic, Spanish mackerel and the bonito. The shell-fish fisheries are also of considerable importance, including some of the choicest products of the sea and valued as food because of their distinctive flavour and their richness in iodine and minerals, essential elements of our diet. The oyster fisheries are of importance in the United States, France and Japan. Lobsters, crabs, clams and shrimp are widely sought after.

The fisheries are a most important source of food. In addition they supply many articles of importance in the arts and industries. Fish meal is gradually winning a place for itself as one of the most valuable protein feeds for hogs, cattle and poultry. Fish fertilizer is generally recognized and widely used as a plant food. The demand for and use of fish oils for soap making, for hydrogenation, including use in lard substitutes, and for many other purposes is increasing. About 60,000,000 gal. of whale oil alone is now produced annually. Shells of molluscs are an important source of raw materials of buttons and various artistic articles. From the shells of the fresh water mussels taken in the Mississippi valley region are produced about 3,000,000,000 buttons per year. From shark hides are made fancy leathers for artistic articles; from fish scales is derived fish scale essence used in the manufacture of imitation pearls; from Japanese pearl farms are derived artificial pearls and from numerous waters of the globe are taken genuine pearls. From the sea-weed industries are derived many products and from the sea itself the indispensable solar salt.

The annual world harvest of fish and fishery products amounts to not less than 30,000,000,000 lb. with a first value of about $1,250,000,000. In addition there is a very considerable draft on water areas by angler and fisherman for home consumption for which no satisfactory estimate can be made. Among the leading nations of the world in the prosecution of fisheries arranged in the relative order of the magnitude of their fisheries are: Japan with a catch of about 5,700,000,000 lb.; United States with 3,000,000,000 lb.; England, 1,700,000,000 lb.; Norway, 1,450,000,000 lb.; Russia, 1,200,000,000 lb.; Canada, 17,190,000,000 lb.; and Spain, 900,000,000 pounds. These seven countries produce about one-half of the world's fishery harvest. Among the other nations producing in excess of 500,000,000 lb. annually are: Scotland, Newfoundland, Germany, France and Portugal. (L. RA.)

VI. FORESTS

The world production and consumption of wood amounts to approximately 56,000,000,000 cu.ft., which is an average of 32 cu.ft. per caput. About 26,000,000,000 ft. is saw-timber, and 30,000,000,000 ft. is firewood.

Increase of Consumption.—As populations grow and as living standards rise and human wants become more complex, timber consumption increases, in spite of the extensive and growing use of substitute materials, and in spite of the tendency to utilize wood more economically. Railroad ties, newsprint and other products of wood pulp, automobiles, phonographs, radio cabinets and many other articles requiring large quantities of wood, all have come into extensive use within recent times.

In Great Britain timber consumption has increased much more rapidly than has the population. Even in France with a practically stationary population, timber consumption was slowly increasing until 1914; that of Germany more than doubled within the century; in the United States at least seven times as much lumber is (1929) used as in 1850. Judging from the rates of increase in these and other important consuming countries, the world's timber needs may be expected to double within approximately 50 years. The per caput consumption in North America of saw-timber (188 cu.ft.) is five times as great as that of Europe, and if the tropical countries south of the United States be disregarded, it is six and one-half times that of Europe. Europe,

South America and Australia use about equal amounts of wood per caput (39 cu.ft.). The proportion of saw-timber to total amount of wood used, however, is quite different, being only one-ninth in South America, two-fifths in Australia and over one-half in Europe. Asia and Africa use comparatively small amounts of wood (9 and 5 cu.ft. respectively).

The total quantity of wood grown in the world each year is roughly estimated at about 38,000,000,000 cubic feet. If this increment were spread evenly over the whole forest area, it would amount to only 5·1 cu.ft. per acre. It is apparent that the present annual growth of 38,000,000,000 cu.ft. is not replacing the present annual cut of 56,000,000,000 cubic feet. The amount of growth each year represents the growth of only a small part of the forest. Vast areas of virgin forests must be left out of the calculation, because in their present condition there is no net growth in them. If all the forests of the world were placed in a growing condition, with a moderate amount of management and protection against devastation, they could produce annually at least 355,000,000,000 cu.ft. of wood, or nearly 50 cu.ft. per acre.

The World's Timber Supply.—With about 5,500,000,000 ac. of productive forest area in the world, bearing heavy stands of virgin timber, having possible growth many times the world's present timber requirements, it would seem that there is enough timber to last for centuries. This would be true if all kinds of wood were equally capable of satisfying human wants. There are about 2,645,000,000 ac. of softwoods or conifer forests in the world; some 1,204,000,000 ac. of temperate hardwoods or broad-leaf forests, and 3,638,000,000 ac. of tropical hardwoods. Although the softwoods and temperate hardwood forests together form only one-half of the total forest area of the world, 91% of all the timber cut and used comes from the softwood and temperate hardwood forests of the Northern Hemisphere, and only 9% from the tropical hardwoods. The softwood forests are furnishing three-fourths and the temperate hardwoods one-fifth of the construction timber of the world. The temperate hardwoods, in addition, supply three-fourths of all the firewood. The amount of standing timber in the tropics is far greater than the amount remaining in the temperate regions, yet until recently, the tropical forests have played a minor part in supplying the world's timber. There has been prevalent an idea that the tropical forests are composed chiefly of cabinet woods, dyewoods and similar kinds of hard, heavy, deeply coloured wood, suitable for furniture and special uses, but not for construction. Recent explorations have shown that there are many excellent construction woods, equal if not superior to the woods of conifers for use in the tropics because more resistant to decay and termites. Before the tropical forests are able to supply a large part of the world's requirements there must be developed adequate systems of cheap transportation and adequate supplies of efficient labour. Another difficulty is that the tropical forests are mostly composed of a variety of species, intermingled in the greatest confusion, and can be exploited economically only if practically all the important species can be utilized. The crux of the world's timber supply problem, during the next two or three generations at least, lies in the available supplies of softwood and temperate hardwood.

Softwood Supplies.—The softwood forests are very largely confined to the cooler regions of the Northern Hemisphere, although some conifers occur in the Southern Hemisphere. The present growth of conifer timber is about 80% of the present cut. The forest capital is being depleted. The principal conifer regions are: (1) North America, including Canada, the United States, and the Sierras of Mexico; (2) northern Europe and central Europe; (3) Asiatic Russia, Manchuria and part of Japan.

In *Canada* the total amount of accessible merchantable saw-timber is estimated at approximately 61,500,000,000 cu.ft. and of pulpwood 52,000,000,000 cubic feet. The forests are being destroyed from two to two and one-half times faster than they are grown. At a total annual drain upon the forests of 5,000,000,000 cu.ft., the accessible stands of virgin forests would be exhausted in about 25 years. In the *United States* roughly only 385,000,000,000 cu.ft. of softwoods of saw-timber size remain. Softwoods comprise two-thirds of the 13,000,000,000 cu.ft. of large timber used annually and more than three-fourths of the sawed lumber. Of the paper consumed in the United States, nine-tenths is made of softwoods. To meet its 1929 requirements, the United States cut about four times as much as grows each year. *Alaska* has great reserves of virgin timber in her coast forests and will contribute largely to the world trade. *Mexico* has about 20,500,000,000 cu.ft. of pine in mountainous forests at an elevation between 7,000 and 10,000 feet.

Europe is barely capable of meeting its softwood timber needs. Just before the World War Great Britain imported 97% of the timber she consumed; France, Germany, Italy, Belgium and the Netherlands imported approximately 30, 47, 65, 77 and 82% respectively. The only European countries that have any prospect of increasing their output of softwood timber for any considerable period or even of continuing to export at the present rate are Sweden, Finland, Russia and possibly Czechoslovakia and Yugoslavia.

In *Asia* the only country exporting on a large scale at present is Japan. In Asia only western and eastern Siberia are reputed to have enormous supplies of virgin softwood timber. Siberian forests, however, are largely unexplored, and little is known of their actual condition. Of the vast forest area of *South America* only 5% is composed of conifers. The bulk is in southern Brazil and adjacent portions of Argentina and Paraguay. The entire region produces only from one-third to one-half as much softwood timber as Argentina alone buys from the United States and Canada. The other South American countries depend upon the Northern Hemisphere for much of their construction timber.

Africa, although it possesses extensive equatorial forests, does not contain enough softwood timber to furnish even the small amounts required locally for construction purposes. In *Australia,* the softwood supply is inadequate for local needs. Much pine, fir and spruce lumber is imported from North America, Europe and north-eastern Asia. The small area of softwood forest in New Guinea and the other islands of the Pacific is insignificant.

Lord Lovat, after a survey of the softwood forests of the world, arrives at the conclusion that, except in Russia, the main softwood virgin timber reserves will be exhausted before very long, and Europe will have to depend more and more on timber raised by the agency of man; that the United States shortage is likely to come more quickly than that in Europe; that the more the American supply becomes centred in the Pacific coast States, the greater is the probability of the industrial States of north-eastern America coming into the European markets for saw-timber in the same way that they do now for pulpwood; and, finally, that as the United States consumes over 13,000,000,000 cu.ft. of softwoods, as opposed to a total European consumption of 9,000,000,000 cu.ft., the United States advent into European markets will have an important bearing upon European prices.

Temperate Hardwoods Supplies.—Like the conifers the temperate hardwoods are confined chiefly to the Northern Hemisphere and are located fairly close to consuming centres. They as a rule occupy the better soils of the more favourably situated lands and, therefore, have been progressively destroyed to make room for cultivation. The large old timber has been depleted even to a greater extent than that of the softwoods. *Europe* has still extensive areas of hardwood forests and even exports special kinds, such as the oak of Poland and Yugoslavia. On the whole, however, the consumption of hardwoods in Europe greatly exceeds the production. In *Asia,* Japan exports small quantities of oak. Walnut and other hardwoods are exported from Asiatic Turkey and the Caspian region. Siberia has about 30% by area of the temperate broad-leaved forests of the world. Except in the Far East, however, they consist of fairly light stands of aspen and birch, much of it valuable chiefly for firewood or pulp and not to be compared with the hardwoods of the United States and Europe. In *North America* the United States now has the largest supply of temperate hardwoods. The other North American regions have no surplus over their own needs. The original stand of approximately 250,000,000,000 cu.ft. of merchantable hardwoods has dwindled to about one-fourth of that amount and is being further depleted at the rate of over 2,000,000,000 cu.ft.

a year. The United States uses nearly 4,000,000,000 cu.ft. of hardwood timber a year, exclusive of firewood, or almost two-thirds of the entire world consumption of temperate hardwood timber. In the temperate region of the Southern Hemisphere including *southern Chile* and *Argentina, portions of New Zealand* and *Tasmania* and the *high mountains of South America* and *Africa*, there are relatively small quantities of valuable hardwood timber, and little or none for export. The outlook for future supplies of hardwoods, however, is probably better than for softwoods, because woods adapted to the same uses can be got from the tropical forests, though they may cost much more. (R. Z.)

VII. NATURAL GAS

The occurrence of natural gas is widespread, both geographically and geologically. Geographically, natural gas is produced in (1) United States: Alaska, Arkansas, California, Colorado, Illinois, Indiana, Kansas, Kentucky, Louisiana, Michigan, Missouri, Montana, New Mexico, New York, Ohio, Oklahoma, Pennsylvania, South Dakota, Tennessee, Texas, Utah, West Virginia and Wyoming; and (2) Canada: Alberta, New Brunswick, Ontario and Saskatchewan. It is found beneath the earth's surface, compressed in small cavities or in porous rock strata. The "gas sand" is a porous rock formation containing millions of small cavities which gas, oil, water or all three together may occupy.

There is a considerable difference of opinion among geologists and chemists as to the origin of natural gas. There are two theories—the organic and the inorganic. In the former, natural gas is considered as having been formed as the result of a tremendous distillation process of decayed vegetable and animal matter millions of years ago. The inorganic theory places the origin of natural gas at a still greater age back into the beginnings of the world, and regards it as a product of heat and volcanic action on carbon possibly deposited when the first crust of the earth was formed. The organic theory is the one more generally accepted. It is a well-established belief, however, that regardless of the process by which natural gas came into existence, the new gas now being generated underground is negligible, so that when the present supplies are exhausted, natural gas will fail.

The by-products of natural gas are natural gasolene, helium, chloroform, formaldehyde, formic and other acids. An important use of natural gas is in the manufacture of carbon black, produced for the manufacture of printer's ink and automobile tyres.

More than 1,000,000,000 gal. of gasolene were (1929) being recovered as a by-product, thus adding to the total supply of motor fuel. Also many millions of cubic feet of liquefied petroleum gases were produced and marketed as raw materials; many thousand pounds of medicinal synthetic and pharmaceutical preparations were made. It has been estimated that 100,000,000 cu.ft. of helium could be produced annually.

The natural gas industry is of most importance in the United States where its magnitude is indicated by the fact that between 15 and 16 million persons living in some 2,500 cities and towns in 24 States represent the domestic consumers of natural gas. In addition possibly 17,000 industrial concerns utilize this fuel. The supply of gas is drawn from more than 45,000 wells covering an area of over 15,000,000 acres. The expansion of natural gas service by means of long high pressure transmission lines to distant towns is one of the outstanding features of the public utility situation in many parts of the United States, natural gas replacing manufactured gas at many important centres.

As in the petroleum industry, pessimistic opinions prevalent a few years ago regarding dwindling supplies of natural gas have been forgotten as a result of the enormous developments of 1929.

Drilling for gas, even with the modern and improved methods, is generally quite uncertain. Expensive drilling is the only means of definitely determining whether gas exists in paying quantities. Thus out of a total area of 3,000,000 sq.m. in the United States, less than 12,000 sq.m. have been productive of natural gas. Geologists are able to indicate probable productive or non-productive lands with a reasonable degree of accuracy, but not with sufficient accuracy to establish a safe estimate of the probable reserve.

In recent years much attention has been given to the conservation of this fuel. Since natural gas is so often incidental to the recovery of oil, it is in many cases largely wasted—acting merely as the vehicle which propels the oil out of the oil sand. (F. W. PA.)

VIII. COAL

Since the estimate of the coal resources of the world was made in 1913 by the 12th International Geological Congress, the World War and the Versailles treaty have changed many boundaries and consequently the resources of many nations. The best revision of these figures for Europe is that by Sir Richard Redmayne, and it is used for European figures in the accompanying table. It does not show the quantities of various kinds of coal in European countries, a task that must be left to some future congress. Neither Sir Richard Redmayne nor the International Geological Survey gives consideration to the exhausted minerals, except that the United States figures are corrected to 1910. Because of the impossibility of correcting all the figures, owing to the changes in boundaries and to inadequate data as to kinds of coal extracted and even as to total extraction in some countries, no attempt has been made, as it should have been, to correct for consumption and waste in mining. The figures for Ireland have been energetically debated. Those given by the congress may be too low, especially in view of some recent discoveries. Nevertheless, the figures of the congress have been taken without change, including those of England, though, there also, extensions of fields have been indicated without definite estimates of their importance. Some changes were made in the figures for Panama, Pennsylvania, Rhodesia, Victoria and British Columbia, the last because the report of J. D. MacKenzie has shown the resources of Vancouver island to be probably overestimated.

Using the figures in the table on p. 865 and the figures for production of coal in the 1925 publication of the Bureau of Mines (Department of Commerce, United States) *Mineral Resources of the United States*, it is found that the 1925 production of coal in the United States was about 582 million tons while the coal reserve in the United States is estimated at 4,231,076 million tons. This shows a supply of over 7,000 years on the basis of the 1925 production. Similarly for the world, with a coal reserve estimated at 7,867,600 million tons and a 1925 production of about 1,498 million tons, a supply of over 5,000 years is shown based on the 1925 production. These figures indicate that, even with large increases in coal consumption it will take many years to exhaust the known world resources, as estimated in 1925.

In the table, A represents anthracite; B is coal with volatile matter between 12 and 35%; C is coal lying between B and a coal D, the moisture in which exceeds 20%.

IX. PETROLEUM

In discussing the petroleum resources of the world the best that can be offered is a scientific guess carefully formulated on the basis of the data now available. Probably the best available study is that by Eugene Stebinger, chief of the Foreign Mineral Section, in the U.S. Geological Survey (made in 1919) on a map upon which he indicated by circles the relative importance of the estimated oil reserves of the different regions. Stebinger's estimates follow, the table on p. 866 expressing first, the relative values of these groups as compared with unit value for the United States, and second, the corresponding quantities when unit value for the United States is 7,000,000,000 barrels.

Since the Stebinger estimates, there have been several careful investigations and reports on the oil reserves of the United States. Petroleum recovered by present methods of flowing and pumping from existing wells and acreage thus proven in the United States amounts to 5,300,000,000 bbl., according to an estimate made by the Committee of Eleven of the American Petroleum Institute in 1925. The report estimates "that after pumping and flowing there will remain in the area now producing and proved 26,000,000,000 barrels of crude oil, a considerable portion of which can be recovered by improved and known processes such as flooding with water, the introduction of air and gas pressure and mining, when price justifies. Improved methods of deep drilling below oil sands now producing will disclose in many areas deposits not hitherto available, which will be tantamount to the discovery of new fields."

The Federal Oil Conservation Board in its report issued in Sept. 1926, said "from the most recent estimates it would appear that the reserves of oil available by flowing and pumping wells from present production and proven fields amount to about 4,500,000,000 barrels." The board points out that there is a wide variation in estimates of the amount of oil left underground in the sands after production ceases with ordinary methods of flowing and pumping which have been hitherto employed.

Dr. David White, of the U.S. Geological Survey, commenting on the Stebinger estimates pointed out that oil indications are

Total north of Equator	5·20	36,400
Total south of Equator	·95	6,655

known in regions not indicated on the Stebinger map although in most such instances the geological conditions seem to preclude reserves of great importance, and that there are in other countries many untested regions in which the geological conditions appear to be favourable for the occurrence of oil fields though surfaee indications of oil have not yet been reported, possibly due in part to insufficient exploration. It is highly probable, he said, that oil in considerable amounts will eventually be discovered in areas of north-west Canada. Other regions outside of the United States in North America which seem likely to make contributions, possibly of minor importance, include Central America, Santo Domingo and lower California. In South America, important new centres of production seem probable along a very extensive strip of territory bordering the east surface of the Andes, and in addition areas of north-eastern Brazil are possibly oil bearing.

Madagascar offers much promise, and conditions favourable for developing oil fields appear to be present not only in Angola and other regions of west Africa but possibly in east Africa also. Australia, Tasmania and New Zealand may yet disclose producing areas of value and it seems reasonable to expect new discoveries of importance in parts of India not on the Stebinger map. Arabia, Palestine, Armenia and Anatolia all offer thoroughly circumstantial indications.

Also it seems rather probable that oil will be produced in portions of Spain, Austria and other countries of western Europe. Considerable extension of the known Russian oil areas may be expected, and Siberia, about which geological information is so greatly desired, and which is said to carry indications of oil deposits in Transcaspia, Turkistan, Kamchatka and notably in northern Saghalien, may reasonably be expected to contain oil-bearing areas. China has oil indications in at least four of her provinces. It appears probable that oil is present, scattered from Persia and Transcaspia, eastward as far at least as Gobi. There are possibilities of oil in the Philippine Islands.

"Evidence as to the probable presence of additional oil reserves in the areas just reviewed," leads White to conclude "that there are probably 20,000,000,000 barrels of oil available in the world in addition to the 43,000,000,000 barrels contained in the regions covered by Stebinger's estimates quoted above, or as much, in round numbers as 60,000,000,000 barrels in all."

Petroleum Substitutes.—The chief substitutes for petroleum now available is oil obtained by distillation from oil shale and from coal. Though oil shale is now utilized in only a few countries, it is widely distributed throughout the world, and the oil shale resources of the United States are so extensive as to furnish a guarantee for the future. In North America oil shale occurs in both Canada and the United States but is commercially undeveloped.

Large areas in the eastern United States and eastern Canada are underlain by dark shales of the Primary or Palaeozoic age that are in many places as rich in organic matter from which oil can be distilled as those mined commercially in Scotland and France. Comparatively little is known about oil shale in South America, though it is said to occur in Argentina, at several localities in Brazil, and in Chile. Unprofitable attempts have been made to distill oil from oil shale in eastern Brazil. In Africa thin beds of unmined shale capable of yielding oil when distilled are reported from Angola, the Belgian Congo, Natal and the Transvaal. Perhaps the largest area of oil shale is in the Belgian Congo.

In Europe the commercial development of the oil-shale industry began early in the 19th century, before the rise of the modern petroleum industry. About 91% of the world's oil shale output is produced in Scotland, 8% in the Autan and Aumance districts in Estonia and France and the remainder in Australia, Germany and Italy. In Scotland the oil-shale industry has been able to compete successfully with the petroleum industry because of the output of valuable by-products made in connection with the oil and because of the remoteness of Scotland from the principal sources of petroleum—southern Russia and the United States. Large deposits of oil shale are reported to occur in northern Russia. Oil shale in Asia is not mentioned in any report that has been seen, but valuable deposits may nevertheless exist there.

Formerly oil shale was mined and distilled in Oceania, at several places in Australia (most of them in New South Wales) and in New Zealand. But the total shale oil produced in all these places has amounted to less than 1% of the world's output.

The U.S. Federal Conservation Board estimates a supply which can be recovered from domestic oil shale, if and when the price warrants its extraction, of 92,000,000,000 bbl., nearly ten times the total quantity of oil that has been produced in the United States from 1859 to 1929. At the present rate of production from wells, this quantity would suffice for roundly 100 years. The estimate is made that the two and one-half trillion tons of bituminous, sub-bituminous and semi-bituminous coal in the United States, within 3,000 ft. of the surface, is capable of yielding about 92,000,000,000 bbl. of motor fuel, more than 300 times the motor fuel production in 1927. It is also estimated that another 12,000,000,000 bbl. of motor fuel may be obtained from the 940,000,000,000 tons of lignite deposits in this country. This would make available an estimated total quantity of 104,000,000,000 bbl. or 4,264,000,000,000 gal. of fuel for motors in addition to the numerous billion barrels of crude oil from wells and oil shales.

(L. M. F.)

METALLIC AND NON-METALLIC GROUPS

Under this heading are discussed the most important metallic and non-metallic substances including Iron, Lead and Zinc, Copper, Aluminium, Nickel, Manganese, Tin, Tungsten, Vanadium, Sulphur, Mercury, Silicon and Mica.

I. IRON

Broad allowances for incomplete information must be made when considering iron ore resources. While no new immense iron ore fields remain to be discovered in either Europe or North America the remaining four continents are still largely unsurveyed. Of known iron ore reserves 15,000,000,000 tons occur in North America, 12,000,000,000 in Europe and 7,000,000,000 in South America. If it be assumed that the remaining three continents are proportionately as well supplied—and against this assumption there is no geological argument—the conclusion is reached that the world iron ore reserve is a total of 90,000,000,000 tons.

The world was in 1929 using annually some 150 million tons of iron ore. This was supplied by many mines, but a few great ore fields were responsible for the bulk of the tonnage. The Lake Superior iron ore region in the United States ships some 60 million tons annually, and the Lorraine field of France and Luxembourg about 40 millions. The fields of Great Britain rank third with around 13 million tons, and the Alabama region of the United States fourth with some 6 millions. After that, ranging from 5 million down to 1 million annually, come Spain, Sweden, Manchuria, western France, Newfoundland, Cuba and North Africa.

The localization of demand may cause more concern than excessive total consumption, for a few ore fields are being drawn upon in exceptional tonnages while other large fields are practically unused. For example, if the present-day drafts continue,

our current estimates of known ore reserves in the different great fields suggest that ore of present day grade will be exhausted in the Lake Superior region within 50 years, in Spain and Great Britain within the century, and in Lorraine in less than 150 years. As against this far-off threat, it may be seen that on the basis of present drafts the Alabama fields should last 300 years or more, while the vast reserves of Brazil, Cuba and Newfoundland have not yet been drawn upon seriously. It is safe to say that the United States can retain its present leadership in iron and steel manufacture for several decades more. It is probable, however, that soon the old primacy of Great Britain and the present American leadership will, in these heavy manufacturing lines, be challenged by a new European competition based on the Lorraine and Norman ore fields, and upon west European coals and cokes.

With regard to the four continents which are less well known and less developed industrially, existing knowledge of relative ore and fuel supplies permits certain deductions of considerable validity. It may be safely assumed, for example, that the known coal supplies of Asia, particularly in China and India, will justify and encourage a large iron and steel industry as local consumption increases; and that under certain conditions the excess product may be exported so as to become a serious factor in European and North American trade and industry. With regard to South America, Africa and Australia, present knowledge of raw material resources suggests that while Australia may easily become self-supporting in the way of steel and iron products, the other two are likely to become important as exporters of iron ore to coal-rich areas, but not as serious producers of iron and its products. Older conclusions as to iron ore exhaustion have been modified seriously by the fact that, within the past two decades, their bases of deduction have been strikingly changed. For 150 years the world iron industry had increased at the rate of 50% each decade; and most earlier estimates prolonged this past rate of increase into the indefinite future. Now, for the first time in the history of modern industrialism, there has been experienced a period of 15 years in which the world iron industry has not progressed; and there is no reason to assume that, whenever this dead point is finally passed over, the old rate of increase will be resumed. It is indeed far more likely that in the future the iron industry of the world will increase at a far slower rate, possibly not above that of the rate of increase of world population. If so the known ore reserves will last for very many generations (E. C. E.)

II. LEAD AND ZINC

Lead.—No quantitative estimate of the copper, lead and zinc resources of the world has been made and it is doubtful whether a reasonable approximation can be made. Looking backward through 50 years there have been periods when it was thought that the supply of these ores was superabundant and other periods when they have seemed to be scarce and opinion has swung from one extreme to another. Especially has this been true in the instance of zinc. However, as to each of these metals, new discoveries, both geographical and technological, may develop valuable resources out of what was previously unknown or worthless. The only conditions under which the world's resources of minerals can be reasonably forecast are when we may say that at least we have so much, as in the instances of coal and iron. Between these extremes it is always a matter of the equilibrium among production, consumption and price. So far as we can see ahead we shall have a sufficient supply of these metals, but we can not see clearly what price we shall have to pay for them, even through the next 10 years.

The production of lead comes principally from the following districts, their percentages being given. South-eastern Missouri, 11·7; Utah, 8·6; Coeur d'Alene (Idaho), 7·5; Tri-State, covering the contiguous parts of Oklahoma, Kansas and Missouri, 5·9; Mexico, 12·6; Spain, 9·2; Broken Hill, N.S.W., 9·5; Sullivan mine, Kimberley, B.C., 7·5; Bawdwin mine, Burma, 3·5. These places account for about 76% of the world's production. Except in south-eastern Missouri, the mines produce a mixed ore which is milled so as to give an enriched galena product for the lead smelter and a blende product for the zinc smelter. Many of the great lead-producing districts of the past were exploited for lead alone, such as Eureka, Nev., and Leadville, Colo., and exhausted Lead-producing districts have waxed and waned more generally and more rapidly than either copper or zinc. Because of this and the failure to make any new important discoveries since 1900, together with the greatly increased demand for lead, experts have taken a pessimistic view and predict a steadily rising price in order to develop poorer ores and remoter mines. About 1925 the new process of selective flotation enabled the profitable mining of large supplies of previously unworkable zinc-lead ores. Lead and zinc production became increasingly interlocked. In 1929 the mines that produce straight lead or zinc ore are few. What will be said hereinafter under "zinc" will therefore apply equally to lead

Zinc.—The world's greatest resources of zinc ore, mentioned substantially in the chronological order of their exploitation, have heretofore been the mines of Upper Silesia; Franklin, N.J.; the Tri-State district of Missouri, Kansas and Oklahoma; Iglesias in Sardinia; Broken Hill in New South Wales; Butte, Mont.; Kimberley in British Columbia; and Bingham and Park City, Utah In 1926 these districts produced about 70% of the world's total of 1,250,000 tons of spelter. The remainder was mined in Bolivia, Algeria, Burma, China, Czechoslovakia, France, Germany, Great Britain, Indo-China, Japan, Mexico, Peru, Spain, Scandinavia, Tunis and the United States. Some great mining districts have lived and died, the most noteworthy of these having been Vieille Montagne (now of Belgium) and Leadville, Colo., but many new districts are being exploited. A maintenance of the output of the present large producing districts—Broken Hill, Franklin and Kimberley—at the current rate for another 20 years at least may reasonably be forecast Upper Silesia, Tri-State, Iglesias and Butte can not be expected so to do, except as to the Blei Scharley mine in Upper Silesia, and the Orphan Girl at Butte.

On the other hand new sources of production are being developed as the results of exploration of new territory, the extension of transportation and improvement of metallurgic processes, which not only make it possible to use profitably ores that formerly were considered refractory but also to give an increased yield from all ores. Among the new districts that are making or are promising a yield are Flin Flon, Sudbury, Buchan (N.F.), Broken Hill (N. Rhod.), Roseberry (Tas.), Mount Isa, Cerro de Pasco (Peru). By 1932 most of these will be producing A general upward trend of price was expected in 1925 as a consequence of the increasing scarcity of zinc ore, but the advent of selective flotation changed that outlook almost immediately Portions of the world, as yet unexplored scientifically, may have great zinc ore possibilities as, northern Canada, wherein important deposits are now being opened; Labrador, Newfoundland, the Andes; Siberia, where there are some great known deposits; Africa, especially in the north and in the Congo region and in Rhodesia; the interior of Australia, and in New Guinea

The production of ores up to the present time has been from deposits whereof there have been surface indications Much of the world's surface is covered by alluvial material which probably hides mineral deposits We are on the eve of advances in geophysical science and methods that are opening the way to the discovery of such hidden deposits. On the side of requirements, the need for all of these metals steadily increases Immediately previous to the World War the annual per caput consumption of the United States was about 8 lb. of copper, 9 of lead and 6·5 of zinc. In the principal countries of Europe the average was a little less, especially of copper. In 1929 the American per caput consumption was about 15 lb. of copper, 12 of lead and 10 of zinc European consumption was, however, still below the pre-war rate A continuing increase may be expected in America, and in Europe a regaining of pre-war rate and then advances. These prospects as to requirements follow from the intimate association of copper and lead with electrification and with storage batteries. For lead there is no general substitute, although aluminium is employed occasionally for electrical transmission. Though hardly to be rated with copper and lead, zinc is used to an important extent in brass, and in paints it replaces lead when the latter becomes scarce. (X.)

III. COPPER

The recent history of the copper industry is closely related to the tremendous development of the electrical industries in the past 30 years. In 1929 nearly 70% of the total annual output of the metal was consumed by those industries. World production for the ten years ending Dec. 31, 1900, was 4,158,513 tons; for the ten years ending Dec. 31, 1927, approximately 13,157,500 tons. In the earlier period the United States furnished 52·3% and in the later 53·9%. South America's proportion rose from 8·4% to 16·2% and Africa's from about 2% to about 5½%. The total recorded output of the world since 1800 has been about 39,600,000 tons, one-half of which has been supplied by the mines of the United States. Indications are that South America, Africa and Canada will increase their proportion in the next ten years. Prior to the exploitation of the large bodies of the "porphyry" or low grade copper ore, it was not customary for the copper producing companies to publish statements of reserves of ore in the ground. The porphyry companies report reserves because in general the exploration of such deposits can be done very cheaply by drilling many years in advance of mining operations.

The so-called "deer level" or "vein" mines still adhere to the practice of not publishing reserves because of the large amounts of money required to explore such deposits much in advance of actual mining, and the probability that if such a policy were pursued, the work would largely have to be done over again when mining operations overtook exploration. The general practice of these companies is to keep exploration four or five years ahead of mining, gauging against past performances the amount to be done by the relative rate of discovery per foot of development. Published estimates of reserves in porphyry mines have included only such material as could be treated profitably at the time of the estimate. Lower cost per ton of ore, increased recovery of metal per ton of ore and higher price of metal all tend to lower the minimum grade of ore that can be treated profitably.

Several important companies are now making money by the extraction of ores which do not contain over 15 lb. of the metal to the ton, while 25 years ago the minimum grade which could be profitably handled was more than double this amount. The Rio Tinto district in Spain has been producing copper since the days of Caesar and in 1924 had an output in the neighbourhood of 70,000,000 pounds. The last official statement of ore reserves by the principal company in this district was made in 1905, at which time the reserves were estimated at 60 years' supply. Since then, highly important discoveries have been made.

The Mansfeld Copper Company mines in Germany have been exploited for several centuries and are now producing between 30,000,000 and 40,000,000 lb. annually. The first recorded production from this district was about A.D. 1200. Attention has been recently attracted to developments in Chile and Peru. One hundred years ago Chile was one of the chief copper producers of the world, and the copper deposits of Peru with associated high-grade silver ores were known to Pizarro. With cheaper sources of supply in the United States, importance waned in these deposits, only to be revived in the present century with the recognition of the availability of large deposits of copper ore containing 40 to 50 lb. per ton, which could be profitably exploited on a large scale.

The latest official estimate of the reserves of the Chile Copper Company shows about 700,000,000 lb. of 2·12% copper, from which about 24,000,000,000 lb. of the metal are recoverable by present known methods. This is equal to 100 years' life at the present rate of output—with, possibilities of additional hundreds of millions, if not billions of tons, which may become available, if costs can be reduced to the present level of those of the Utah Copper Company now operating profitably on 1% ore. This ore body, together with certain others, constitutes a very large reserve of copper. These occurrences do not include all the deposits of copper amenable to even the present methods of exploitation, to say nothing of the known deposits certain to be developed through future economies. Similar considerations apply to the still more recent developments in Africa, where one company already estimates its reserves at approximately 85,000,000 tons of ore averaging 6·87% copper. The existence of ore of this grade in this area is the best evidence of the presence of greater amounts of copper contained in ore carrying only 2% or less, which, upon the development of adequate transportation and labour supply, will eventually become commercially available.

To summarize the situation as to the world reserves of copper in the so-called "porphyry" deposits, which, although known, were unavailable at the beginning of this century, these deposits are now supplying one-half the world's needs and have resources sufficient to last 50 years at the present rate of production with present methods. The "vein" mines in the United States have in the past supplied over 65% of the output and may long maintain this proportion. At least we might estimate that their present resources are as great as those of the porphyry group. The American Bureau of Metal Statistics has published consumption figures showing clearly the relatively slow recovery of the European industry since the World War compared to the marked progress in the United States. At the same time the figures point definitely to an increasing European demand for the metal. Great Britain, France and Germany have an aggregate population of 150,000,000 people. If their per caput requirements eventually reach the present level of those in the United States (15·54 for 1926) they will require an additional one and one-quarter billion pounds of the metal per annum. On the other hand, the existing facilities for production, plus those in process of development and projected, are sufficient to meet these requirements within the next ten years if they are needed. There is nothing to indicate any present failure of the supply of copper. Copper is practically indestructible and as the total supply of metal above ground increases, the amount of second-hand metal or scrap available for consumption increases and the need for virgin copper from the ground decreases.

(A. NOT.)

IV. ALUMINIUM

The aluminium content of the earth appears to be concentrated near the earth's surface. F. W. Clarke and H. S. Washington estimate that the earth as a whole contains only 1·79% of aluminium, but that the outer crust, to a depth of 10 m., contains 8·05%. This is equivalent to an aluminium oxide content of 15 to 16%. The ores of aluminium are employed for the production of aluminium, alumina, aluminous abrasives, cement, aluminium chloride, alum, etc. From economic considerations those ores are employed which yield the maximum number of units of alumina per unit of cost. For this reason the pre-eminent ore is bauxite, which contains 50 to 60% of alumina. The bulk of the world's aluminium is produced from alumina extracted from bauxite by digestion with caustic soda—the well known Bayer process. In 1929 about four tons of bauxite would produce a ton of aluminium. Bauxite of commercial grade is available in extensive deposits in Europe, North and South America, Asia and Africa, but the bulk of the production comes from the first three of these continents. E. C. Eckel, upon the assumption that the available bauxite per square mile of area is the same in other continents as in Europe, has estimated the world's bauxite reserves as about 2,500 millions of tons. In 1928 the world's consumption of bauxite was only about 1,500,000 tons. Allowing for substantial annual increases in consumption, therefore, the world's supply will last a long time.

The aluminium industry was in 1928 using the purest bauxite, particularly with respect to silica, and much of the world's supply of bauxite is less desirable for the Bayer process. However, there are other processes being developed which can handle lower grades. Among these are the electric furnace process of C. M. Hall as recently developed by Aluminum Company of America, as well as the processes of Pedersen and Haglund. Other ores of aluminium, particularly certain of the silicates, are proving susceptible to treatment by processes now under development, so that when they become economically important they can be utilized. This will still further extend the available supplies of aluminium ores. The consumption index of aluminium is increasing more rapidly than some of the older, commonly used metals. Up to 1929 aluminium has competed principally with copper and other non-ferrous metals on a price per volume basis. With the greater realization, however, of the economic value of the lightness and strength of aluminium and the development of strong, light alloys, aluminium

competition with steel will increase in the future. This will be accompanied by improved production and fabrication methods. Uses of the compounds of aluminium, as in the abrasive, cement and chemical industries should expand rapidly. For all these demands, the supply of aluminium appears ample for hundreds of years. (J. D. E.)

V. NICKEL

While nickel is one of the elements of most common occurrence in the earth's crust, the commercially important ore deposits are confined to two localities, Canada and New Caledonia. Of these Canada is by far the more important, producing (1929) approximately 90% of the world's nickel. While there are numerous other known nickel deposits, it is improbable that this percentage will be much affected for many years. The ore deposits are of two kinds: *sulphide deposits*, where the nickel occurs in conjunction with copper and sulphur; and *silicate deposits*, where the ore occurs as nickel silicate (generally as a double silicate of nickel and magnesium). The Canadian deposits are typical of the first type, those of New Caledonia of the second type The known Canadian nickel deposits are located in Sudbury district, Ont., within an area 40 m long by 30 m. wide. While some 35 deposits of varying size and richness have been located since the original discovery in 1883, only a few of these mines are worked. Thus in 1929 The International Nickel Company was operating only the Creighton mine, and was at work developing the Frood mine for future production. The Mond Nickel Company was developing the Frood extension and operating the Garson and Levack mines On the basis of diamond drilling and other exploratory work it is estimated that there is proven ore in sight of approximately 175,000,000 tons, containing between three and four million tons of nickel. With a world consumption of approximately 40,000 tons of nickel per annum, this is equivalent to 100 years of proven ore

The New Caledonia deposits, originally discovered in 1865, rapidly assumed primary importance, and from 1875 to 1880 were the chief producers of the world's nickel. In 1905 the New Caledonia deposits were surpassed in production by the Canadian mines, which since that time have maintained their pre-eminence. The peak of New Caledonia production was reached in 1911 It is now a steady producer of about 10% of the world supply Owing to the character of the New Caledonia deposits it is impossible to give any figures on ore resources, or potential production It is known that there is still a large amount of ore on the island, and it is believed that New Caledonia will continue to produce nickel for many years Besides these two localities deposits of nickel ore are known to exist at a number of places. In general these conform in type to one of the two classes mentioned above, but the size and character of the deposits render them non-commercial under present economic conditions The best known of these are deposits of the sulphide type ores, in Norway, Finland, Sweden, Germany and South Africa, and the silicate type ores in Madagascar, Germany and Greece Nickel ores in the United States are comparatively unimportant (J F TH)

VI. MANGANESE

World resources of manganese may be divided into two classes: manganese ore containing more than 35% manganese; and manganiferous ores containing less than 35% manganese In countries where manganese ore production is large and consumption small the second class is of small interest, whereas if the opposite conditions prevail manganiferous ores may be of considerable importance. In modern steel-making practice the trend is toward a greater use of high manganese pig iron (*see* MANGANESE STEEL) and manganiferous ores are extensively used in blast furnaces. This practice is particularly useful where the production of ferro-manganese grade ores is small, as the high manganese in the pig iron results in a higher manganese content of the steel during refining and thus in a saving of expensive ferro-manganese The use of high-manganese iron is common in Germany and is becoming so in the United States.

The largest resources of manganese ore are in Russia, India, Brazil and the Gold Coast of Africa. The largest developed deposit is the Tchiaturi deposit in the Republic of Georgia (Caucasus). This has been estimated to contain from 40,000,000 to 200,000,000 tons. The Nikopol deposit in south-eastern Russia has been estimated to contain upwards of 10,000,000 tons. The deposits in India are numerous and it has been estimated that an annual production of 600,000 tons could be maintained for at least 40 years. The main deposits are in the Central Provinces. The Gold Coast resources are estimated at 10,000,000 to 20,000,000 tons and the Brazilian resources at 15,000,000 tons. Large deposits of high-grade ore are also known to exist in Dutch East Indies, Chile, China, Cuba, Czechoslovakia, Spain and Bechuanaland Protectorate of South Africa. The reserves of manganese ore in the United States of America are estimated at about 1,500,000 tons Of manganiferous ores there are some 40,000,000 tons. The world's present demands have been estimated at 2,500,000 tons (C H. HE)

VII. TIN

Tin resources of the world are generally—and probably correctly—considered to be smaller than those of any of the other major industrial metals and nearer exhaustion. Necessarily in making this statement price is a factor to be considered. If the market price soars, deposits of progressively lower grade will become profitable Likewise, economies to be effected in mining, and higher recoveries resulting from improved methods of ore dressing and smelting will tend to expand the resources of the world. Still another factor is the possibility of discovering new fields of substantial importance, the most likely area being interior Africa, with French Indo-China, Siam and China offering excellent opportunity. In 1926 some authorities forecast a fairly uniform rate of production for ten years to be followed by a gradual decline, because of the exhaustion of the producing fields To-day even the more apprehensive foresee supplies to assure any reasonable demand for a substantially longer period

For a number of years the Federated Malay States have contributed about one-third of the world's output of about 150,000 tons almost entirely from placer operations. In 1928 as a consequence of the putting into operation a large number of new modern dredges the percentage was increased to about 40, the world total at the same time passing 170,000 tons. Still further increases in the Malay States are to be expected, and with the introduction of bigger and better dredges, the reserves of exploitable grade are steadily expanding Bolivia was the next largest producer in 1928 with 25% of the world's total compared with about 22% in recent years Production comes from lode mines mostly in one district The largest individual producer is planning a substantial expansion in production. Placers are being developed that may augment the output Improvements in ore dressing and metallurgy are likely to make practicable the winning of lower grade lode ores, of which there are good supplies. The Dutch East Indies, third largest contributor, account for about a quarter of the world's supply The mines are placers and, being controlled by the Government, no expansion in output took place in 1928. Nigeria, Siam and China, each with about 5% of the world's total output, have fields possessing possibilities of expansion and a reasonably long life. (A B. P.)

VIII. TUNGSTEN

The metal tungsten has played a very important part within the last quarter of a century in the progress of the electrical and mechanical arts Recent developments indicate that its importance will be still greater in the coming years It is a chief component of tool steels and enters into the manufacture of heat-resisting and non-corrosive steels. Recently tools have been invented consisting of pure tungsten carbide imbedded in a metallic matrix which promise to revolutionize the art of cutting and shaping not only metals but also such unworkable materials as porcelain, glass, bakelite, etc. In 1929 tungsten formed the light filaments, contact points and X-ray targets of the electrical industry besides entering as a component into magnet steels With the rapid strides made in radio and television its expansion into the electric industry may grow to huge proportions

Nature has fortunately provided a very wide-spread mineralogical occurrence of tungsten, both in the primary and secondary formations of the earth The primary deposits are invariably

associated with granitoid rocks and are most important. The secondary deposits form the lesser resources of tungsten minerals. Oceania and the Continents of Asia, Australia, North and South America, Europe and Africa have all, one time or another, been commercial producers of tungsten minerals. Tungsten has been a comparatively cheap metal and it has been the endeavour of producers to obtain their ore supplies as cheap as possible. The supremacy of tungsten production has floated from country to country as the surface ore was exhausted and more expensive deeper mining made necessary. Burma and the Federated Malay States held the bulk of the tungsten market until the World War. Then North and South America began to produce ores. China in 1917 produced only about 5% of the total output of the world, whereas in 1927 it produced over 68%. From indications in 1929 the United States bid fair to become a large factor in tungsten mining, as they are the largest consumer. Owing to its great importance in warfare it is the endeavour of the principal Governments of the world to keep their indigenous tungsten resources under development in spite of the lower cost of foreign minerals.

The important commercial minerals of tungsten fall under two main groups, the first group being tungstates of the metals iron and manganese, and the second group being the tungstate of calcium. The pure iron tungstate mineral is known as ferberite, and the manganese tungstate as hubnerite. The mixed iron manganese tungstates are called wolframite. The only important mineral in the second group is the calcium tungstate, known as scheelite. Until recently scheelite was the more coveted mineral for metallurgical purposes owing to its greater purity, but progress in smelting and reduction practice has offset this advantage.

IX. VANADIUM

The tremendous advances made within the last few years in the transportation industry, be it railroad, automobile or aeroplane, have very markedly brought forth the importance of the metal vanadium. It is always used in the metallurgical industry as an alloy. It is added to metals in very small quantities, yet produces in the finished metal very marked changes in physical properties. The present day mass production in the automotive industry or the developments in the aeroplane motor would not have been possible had it not been for the development of vanadium metallurgy. Vanadium has also played an important part in armaments.

Vanadium is one of the most widely distributed elements in the earth's crust, being present in almost all igneous rocks. However, occurrences of the metal in concentrated mineral deposits are scarce. The one dominating occurrence of vanadium is at Minas Ragra in Peru, South America, being the source of 85% to 90% of the total vanadium produced in the world. The other workable deposits of vanadium have up to now also been confined to the Western Hemisphere, in Mexico and the western parts of the United States, especially the States of Colorado and Utah. Very recently, however, deposits containing vanadium have been developed on the African continent, in Rhodesia and in the territory formerly known as German South-west Africa and now under British mandate. There are other less important occurrences of vanadium known on the European continent, in the iron ores of Sweden and Norway, and also in those of Luxembourg. However, these have no commercial significance. The mineral found in the most important deposit in Peru is patronite, a vanadium sulphide. In Colorado and Utah the occurring minerals are roscoelite, a vanadium silicate, and carnotite, a radium-bearing uranium vanadate. The ores of Mexico and Africa are descloizite and mottramite, complex vanadates of lead, zinc and copper.

The already known resources of vanadium minerals in the world fully assure an adequate supply for approximately the next 35 years. At the same time considerable effort is directed towards finding new deposits or further exploiting the known ones. The consumption of vanadium is augmenting yearly. Vanadium is an essential constituent of high-speed tool steel, the demand for which has increased tremendously with the expansion of mechanical production. It is also used in heat-resisting and non-corrosive steels. Very recently developments in the chemical industry will tend to make large demands on vanadium resources. Vanadium is beginning to be used in the textile, varnish, linoleum and rubber industries, and a particularly important application seems to be the use of its oxide as a catalyzer in the manufacture of sulphuric acid replacing platinum. Vanadium may also be applied in the agricultural and pharmaceutical industries. Marked strides have been made in the metallurgical treatment of vanadium minerals so that materials previously considered low grade or useless have been made available to the industry, thus augmenting the sources of raw materials and thus adding to vanadium reserves. (B. D. S.)

X. SULPHUR

Native sulphur, or brimstone, occurs in many places throughout the world, generally either in beds of gypsum, limestone and associated rocks or in the vicinity of active and extinct volcanoes. The principal extensive deposits are found along the Gulf coastal plain of the United States, in two places in Sicily, at several points on the mainland of Italy, in Japan, Spain, Austria, in the Aleutian islands, Alaska, in the Chilean Andes, South America, in China, India, Russia and in several of the South Sea islands. Until 1905, Sicily controlled the sulphur industry, approximately 85% of the total world's supply being produced in Sicily and Italy.

It was discovered many years ago when drilling for oil that sulphur existed in large quantities in the saline dome formations of the Gulf coastal plain of the U.S. No successful method was devised for winning this sulphur until the development of the Frasch process about 1900. (*See* SULPHUR.)

With sulphur obtained at low cost by this process, the deposits of Louisiana and Texas became the principal sources for the world, the Sicilian production taking second place. Since 1923 about 85% of the world's supply has been from the Texas field, 12% from Sicily and 3% from Japan, Spain and other countries.

It is estimated that the Texas known reserves are at least 50,000,000 tons. That more discoveries will be made is almost assured. The world's consumption of native sulphur since 1923 has averaged yearly about 2,300,000 metric tons. No recent data have been published regarding the reserves in Sicily. It is therefore to be seen that the supply will apparently be adequate for many years. Other deposits in the United States are of considerable extent, but are not of present day commercial value. Pyrite ores, gypsum and waste smelter gases may be considered sources of sulphur, competing with native sulphur.

The chief use for native sulphur is to burn it to sulphur dioxide gas for the manufacture of sulphuric acid or for the production of sulphite liquors for paper pulp manufacture. For certain chemical purposes, especially for the production of agricultural insecticide sprays, and in the manufacture of rubber and sulphuretted products, native sulphur has a distinct field of use. (A. E. W.)

XI. MERCURY

Although free mercury is found in the form of amalgams, and approximately 25 ores containing mercury are known, cinnabar is the only ore found in sufficient quantity to be of commercial importance. It is rarely found in a high degree of purity, but is always mixed with large quantities of rock. Italy and Spain (1929) furnish over 80% of the world's mercury. Nearly all of Italy's production comes from the Idria and Monte Amiata districts. In Idria, the ore is rapidly approaching exhaustion, but in Monte Amiata the quantity of reserves now under development is estimated at 20,000 metric tons, indicating a life of ten years at the 1929 rate of production, and is supplemented by large undeveloped areas in the same region, which insure a supply for a much longer time. In the Almaden district, which furnishes the bulk of the Spanish supply, the reserve is estimated at 40,000 metric tons or more, assuring a supply for 25 years. The United States holds third place in production, but the richest fields are fully or nearly exhausted, and a thorough survey has revealed no important possibilities. Production in Czechoslovakia and Russia has increased, each reaching 2% of the total. Mexico supplies about 1% of the total, and the rest of the world less than 1%.

Production in the principal fields of Italy and Spain is regulated by agreement. The principal uses for mercury are: (1)

drugs and chemicals; (2) fulminates in explosives; (3) pigments for paints, including marine anti-fouling points; (4) electrical apparatus, including radio supplies; (5) treatment of felt for hats; (6) mercury vapour engines. In the mirror industry, the use of mercury has been almost entirely replaced by deposition of silver, and the amalgamation process for the extraction of gold and silver, once important, has been largely supplanted by the cyanide and flotation processes. The use of mercury vapour engines is increasing. (F. F. R.)

XII. SILICON

While the element silicon does not occur free in nature, its compounds make up approximately 88% of the earth's crust. Silicon is found in the form of silicon dioxide, either as quartz or as silicates, generally in combination with alumina (clay, shale, feldspar, etc.). Industrially useful and commercially important, silicious resources are consequently generally available in all countries. Of primary importance are hydrous aluminium silicates, broadly termed clays, varying in purity of chemical composition and in physical properties from kaolin, which approaches the pure aluminium silicate, kaolinite, to the shales which contain enough kaolinite to render them workable in ceramic processes The uses which clays find in industry may be summarized as follows: *kaolins* (white burning clays of high purity) for making paper, porcelain and chinaware, electrical porcelain, wall tile and rubber; *fire clays* (high fusing clays generally with some free silica and 1 or 2% of iron, lime and alkalies) for fire-brick and other metallurgical refractories, glass-house refractories, gas retorts and retorts for zinc smelting and in general for use to withstand high temperatures, sewer pipes, chimney tiles, clay and graphite crucibles and in the manufacture of aluminium sulphate; *common clays* and *shales* (miscellaneous rocks which become plastic on grinding in water) for common brick, sewer pipes, building tiles, portland cement, electrical conduit tiles, chemical stoneware.

Silica (silicon dioxide) occurs chiefly as quartz, in the form of sand, sandstone, quartzite rock, vein quartz and rock crystal and also as infusorial earth. Quartz sand and crushed quartzite rocks find uses in abrasives, glass, glazes and enamels, silica refractories, electric furnace products (silicon carbide and many metal-silicon alloys), porcelains, sand lime brick and other ceramic products. Vein quartz or rock crystal is necessary for the production of transparent fused silica, but the translucent material may be made from quartz sand. Rock crystal in large sizes is important as a gem. Gannister, a form of quartzite, is employed in manufacturing silica refractories. *Infusorial earth,* or diatomaceous earth, is employed for thermal insulation and for filtering and clarifying in chemical manufacture, and "fullers' earth" which is properly a "clay," is similarly used for bleaching and clarifying oils and fats. Among the useful silicate minerals is feldspar, of primary importance in porcelain, whiteware and other ceramic products, glazes, enamels and glass. The minerals sillimanite, andalusite and kyanite are important raw materials for electrical insulators and also for greatly improved metallurgical refractories. *Asbestos*, a hydrous magnesium silicate (chrysotile) is woven into fire-resisting fabrics and for brake linings, and the shorter fibres are used in shingles and roofing sheets, coverings for the insulation of steam pipes and for parts of electrical equipment. *Talc* and *mica* are also important. (E. W. T.)

XIII. MICA

The commercial importance of mica is due to its highly developed cleavage, which permits the manufacture of dimensioned parts with great accuracy; its transparency; flexibility; stability at high temperatures; and insulating qualities. No satisfactory substitute is known nor has any medium developed which can replace mica in modern electrical equipment. Mica is an essential constituent in the ignition system of the internal combustion motor and therefore of great importance in the automobile and aeroplane industries. The rapid development of wireless communication has also been dependent upon abundant supply of high grade mica. Mica production is restricted to the ancient, stable, land masses such as the peninsula of India, central and southern Africa, Madagascar, the Appalachian area in North America and the eastern areas in South America.

The micas of economic importance are of two varieties: *muscovite,* found in many localities; and *phlogopite* found in Madagascar and Canada. India, the United States, Canada and Madagascar produce over 90% of the world's mica. In none of these countries is there any immediate indication of exhaustion of the deposits. Production at the 1928 level may be maintained for an indefinite period. Continued search for new deposits may be depended upon to add to known resources. Mica of good quality is produced in minor quantities in Central and South America, Africa, Australia and Siberia. (W. M. My.)

PRECIOUS METALS GROUP

This classification includes the Platinum group of metals (Platinum, Palladium, Iridium and others) and Gold and Silver.

PLATINUM METALS

Prior to the World War 95% of the world's supply of platinum metals came from placer mines in the Ural mountains, Russia. The platinum-producing placers of the San Juan river in the Choco district of Colombia, South America, became the largest source of supply during the World War and have continued important. Nickel-copper ores became an important source of platinum metals when electrolytic refining was started on a large scale in 1907 by the International Nickel Company and the Mond Nickel Company, both of which operated mines in the Sudbury district of Ontario, Canada. The platinum metals have been produced in various provinces of Australia, and Tasmania was for many years the largest producer of osmiridium. In 1921 Osmiridium was first recovered as a by-product from the treatment of gold ore and tailings in South Africa, still the only reliable source

Various other countries have yielded small quantities of the platinum metals, but are not important sources of supply. In 1925 a discovery of platinum group metals was made in certain basic igneous rocks in the Rand district of South Africa. Development of these deposits over the last two years has demonstrated the importance of this field. A small production of the metal was made during experimental work on the complex metallurgical problem, which must yet be satisfactorily solved if these relatively low-grade platinum metals-bearing copper-nickel ores are to compete successfully with the placer fields of Russia and Colombia. Remelted or refined scrap platinum metals form a very important part of the yearly supply of the noble metals; the total recovered in 1927 in the United States alone was 53,072 troy ounces.

Africa.—So long as the mines of the Transvaal continue their system of treating the "banket" gold ores on corduroy or similar tables, there should continue to be produced at least 5,000 oz. of osmiridium a year. In 1924, there was discovered in the Transvaal what appears to be one of the largest and most important sources of platinum metals in the world The deposits are in lodes and pipe form. The development so far accomplished has shown very large reserves of ore carrying 4 to 6 dwt. of platinum metals a ton. The metallurgy is complex and, up to 1928, had not been satisfactorily solved There is an immense reserve of platinum metals in the South African deposits, which will eventually be available for consumption. It is reported that platinum has been discovered in alluvial deposits covering an area of at least 40 sq m. in Sierra Leone, north of the Gulf of Guinea.

Australasia.—Platinum occurs with gold, tin and monazite in beach sands on the north-eastern coast of New South Wales, at the mouths of Clarence and Richmond rivers. Apparently the production from this source has been small. Platinum has also been found in some masses of ironstone at Darling creek and Mulga springs, near Broken Hill. Most of the platinum produced in New South Wales has come from alluvial washings at Fifield and Platina Of late years the production from this district has been greatly diminished. Some quantities of platinum are known to occur with tin, monazite and gold in the beach sands at the south-eastern border of Queensland. So far as can be learned, little platinum has been saved from these deposits. There are osmiridium fields, 20 m. west of Waratah, Tasmania, on Nineteen Mile creek, a tributary of Savage river. The Adams River field in west-central Tasmania was discovered in 1925, but was largely worked out by 1927. Papua, the south-eastern part of New Guinea, has

produced a little osmiridium from placer deposits in the Waria, Gira and Arkora rivers on the south side of the Stanley range.

Japan.—Osmiridium and platinum associated with magnetite, chromite and cinnabar occur in the placers of Yubari-gawa, Pechan and Usotannai rivers, in the central and northern parts of Hokushu island. A small yearly production has been made.

Europe.—About 95% of the platinum in the world has come from five districts on the European and on the Asiatic side of the Ural mountains of Russia. The platinum is washed from creek and river gravels from localities eroded from masses of peridotite and pyroxenite. To a considerable extent the production is still obtained from small hand-workings, but recently large electric dredges have been installed, which are able to handle poorer grades of materials. The average yield is said to be about 0·07 oz. of platinum per metric ton of gravel. Professor Lipovsky estimates that there are reserves of 7,000,000 oz. of platinum in Russia.

North America.—Several creeks, including Dime creek on Seward peninsula, and some tributaries of Copper river in south-central Alaska, have yielded a little placer platinum, but cannot be considered as sources of regular supplies. The chief source of platinum metals in Canada is in the nickel-copper ores of the Sudbury district of Ontario. These deposits are extremely large, are in strong hands and should continue as regular producers of platinum metals for many years to come. The Tulameen river in southern British Columbia has been the source of a small yearly production of crude placer platinum. Most of the gravels have been worked several times and the district holds little promise for the future. In the United States the principal production of crude platinum has come as a by-product of gold dredging on the east side of the Sacramento and San Joaquin river valleys in California, though a minor quantity of metal has been saved on Cottonwood creek, in Shasta county, Hayfork creek, in Trinity county, Calif., the Illinois river, in Josephine county, Ore., and from the beach sands at various places from Eureka, Calif., north to the mouth of the Columbia river, Ore. The production in recent years has been declining, and, with the exhaustion of known dredging ground by about 1938, the output will be very small. A small quantity of palladium-nickel-copper ore has been produced from mines on Prince of Wales island, south-east Alaska, near Goodsprings, Nevada, and Albany, Wyoming.

South America.—Platinum was first discovered and described in material from Colombia, and in 1788 the metal was being largely used in jewellery and in the manufacture of crucibles. At the end of 1788 there had been collected from Choco 3,820 Spanish pounds of the metal. In 1824 the annual production from Choco is said to have amounted to about 1,000 pounds. The gold-platinum alluvial deposits of Colombia cover an area of more than 5,000 sq.m., which lies west of the central ridge of the Colombian Andes, in the Atratro and San Juan drainage basins, and extends south of the mouth of San Juan river along the coast to Mira river. The richest deposits and those most worked are near the headwater of San Juan river, principally on Condoto river. In the gravels of the San Juan drainage there are about equal quantities of gold and platinum, but in the Atrato basin platinum constitutes approximately 15% of the value, the remainder being gold. The most productive area is held by American companies. What appears to be a conservative estimate gives a total of 336,000,000 cu.yd. of gravel that can be considered as reserves, with 68,000,000 cu.yd. as proved ground capable of producing at a profit under present working conditions. This estimate of reserves may be increased in the light of future work.

Uses of Platinum Metals.—The essential uses of these metals are in the chemical, electrical and dental industries. Pure platinum is required in the chemical industry for catalyzers in the manufacture of sulphuric acid by the contact process and in the manufacture of nitric acid from ammonia. Pure platinum utensils of various kinds, including crucibles, dishes, tongs and triangles, are required in every chemical laboratory. Platinum-iridium alloys containing from 15 to 50% iridium have been used very extensively by the electrical industry, but several satisfactory substitutes have been developed. Tungsten, molybdenum and nickel-chromium alloys are the principal substitutes, but their use has not done away with the need for platinum in the industry. The principal use of platinum-iridium alloys in electrical work is in contact points, and the proportion of iridium necessary in the alloys is directly dependent on the intensity of the current passing through the contacts and the speed at which the contacts move.

The chemical industry in the United States since 1918 has used between 5 and 7% of the platinum metals consumed and it uses relatively little except platinum. The dental industry uses approximately 14% of the yearly consumption of platinum metals and uses nearly equal quantities of platinum and palladium with relatively little iridium. Its use of platinum has decreased and of palladium has increased since 1925. The electrical industry normally consumes from 13 to 19% of the United States total of platinum metals, using 12 times as much platinum as palladium and eight to ten times as much platinum as iridium. There is an increasing demand for iridium with the development of aeronautic internal combustion engines. The jewellery industry is the largest market for platinum group metals, absorbing from 57 to 65% of the yearly turnover. It normally uses about 40 oz. of platinum to one oz. of iridium, but since 1925 has been consuming more palladium and the minor metals of the platinum group, including rhodium and osmium. The miscellaneous uses of platinum include the photographic-chemical industry as the largest consumer, and the gold pen industry, which uses either the natural osmiridium or in recent years a synthetic osmium-iridium alloy, which is said to be a satisfactory substitute for the native "point metal."

The metals of the platinum group are essential to three important industries, yet these three take only about one-third of the yearly total. The jewellers take approximately the remaining two-thirds and are the stable market for the noble metals. Stated in another way, the platinum metals are essentially "luxury metals" and their continued demand on a large scale depends more on style in jewellery than on any other factor. Platinum jewellery can be made in more intricate design with equal strength than in other metals, according to the makers, and sets off gems and the costume as no other metal can. It would appear that the known reserves of platinum-group metals in Russia, Colombia and South Africa are sufficiently large to supply world demand for many years to come, with the possible exception of a supply of iridium. Iridium is an essential constituent of all "hard platinum." Its chief source is from the natural alloy osmiridium and this alloy is extremely rare. Had it not been for a change in practice in South Africa for the treatment of the gold ores of the Rand in 1921 there would have been a serious world shortage of iridium.

(J. M. Hi.)

GOLD

Since the rise of the Spanish empire in the New World, £4,245,000,000 of gold has been produced. Only 15% of this amount was produced between 1493 and the Californian alluvial discoveries of 1848, and over half in the first 27 years of the present century.

Of the total gold produced since 1493 the Transvaal has contributed 22%, the United States 21½% and Australasia 17%. The following table shows the value of the production in different areas:—

Locality	Total amount.	Amount produced in 1912–27.
	£	£
United States (practically since 1849)	911,000,000	220,000,000
Transvaal (since 1884)	929,000,000	604,000,000
Australasia (since 1851)	715,000,000	98,000,000
Russia and Siberia (since 1814)	378,000,000	48,000,000
Mexico (since 1521)	146,000,000	46,000,000
Canada (since 1858)	132,000,000	74,000,000
India (since 1880)	70,000,000	32,000,000
Rhodesia (since 1898)	66,000,000	46,000,000
West Africa (since 1880)	28,000,000	19,000,000
	3,750,000,000	1,187,000,000
South America, etc. (since 1493)	869,000,000	128,000,000
Total 435 years	4,245,000,000	1,315,000,000

Eduard Suess has calculated that during the period 1848–75 the annual yield of £22,000,000 was obtained as to £19,300,000 or 88% from alluvial and as to £2,700,000 or 12% from lodes. By 1890 the output of £24,500,000 was derived as to £11,000,000 or 45% from alluvial, as to £11,500,000 or 47% from lodes, and as to £2,000,000 or 8% from the stratified banket of the Transvaal. So productive has the last source of the metal become, that of the world's gold production of £82,000,000 in 1927, £43,-000,000 or 52% came from banket, while lode mining yielded £34,000,000 or 42%, and alluvial had probably fallen to £5,000,-000 or 6%.

Though production has advanced so rapidly in the course of the present generation, there are indications that, apart from any new discoveries which may yet be made, the output reached its zenith in 1915. Thereafter, partly as a result of restriction of production due to the increased costs resulting from the World War, but partly also as a result of exhaustion of mines, the annual total fell from £96,400,000 to £65,500,000 in 1922 (a year exceptionally affected by a white miners' strike in the Transvaal), recovering to £82,000,000 in 1926 and 1927.

The commanding position of the British empire regarding gold production is indicated by the fact that it was responsible in 1927 for 71% of the total production. The Transvaal alone yields three-fourths of the empire's and over half of the world's total. Such countries as Australia and the United States are declining.

The destination of the gold taken out of the earth since 1493 has been estimated as follows: industrial arts (Europe and America), 31%; India, 14%; China and Egypt, 3%; available as money, 52%.

Gold Consumption.—The industrial arts and India have the first call on gold production They largely increased their demands after the outpourings of gold by California and Australia after 1848 and 1851, thereby serving to moderate the great increase of prices of commodities which took place, and largely maintained their rate of absorption for some time after the gold output had commenced to decline. Again, after production in the 'nineties started its great climb to the height of 1915, they increased their demands exceptionally until for the 20 years to 1924 industry absorbed £20,000,000 and India £15,000,000 per annum. On the whole they have taken 45% of the aggregate gold production, and all of this has been effectively withdrawn from the amount available as money, for India's imports and its own production have been wholly turned into jewellery, possessions and hoards.

The distribution and redistribution of the aggregate output between the end of 1913 and the end of 1926 is as follows.—

Distribution of World's Aggregate Gold Production in 1913 and 1926

	Dec. 31, 1913.		Dec. 31, 1926.	
	£	%	£	%
State banks and treasuries				
Other banks	1,044,000,000	33½	1,918,000,000	46
In circulation	59,000,000	2	13,000,000	½
Not traceable (including private holdings)	483,000,000	15½	107,000,000	2½
			147,000,000	3½
World's stock of gold money	1,586,000,000	51	2,185,000,000	52½
Absorbed by industrial arts (Europe and America)	1,042,000,000	33½	1,274,000,000	30½
Absorbed by India	392,000,000	12½	597,000,000	14½
Absorbed by China and Egypt	100,000,000	3	107,000,000	2½
World's gold output (from 1493)	3,120,000,000	100	4,163,000,000	100

The figures set down for money in circulation are guesswork and may be too high, but the table serves to show that while about £400,000,000 has been taken out of the pockets of the public, through monetary changes produced by the World War, about twice that amount has been added to the stocks in central banks.

World's Resources.—In the early days of the Rand, *i.e.*, from 1893 to 1901, experts like Hamilton Smith, Bergrath Schmeisser, Messrs. Hatch & Chalmers, Dr. George F. Becker and John Hays Hammond estimated that the total production of the field down to a vertical depth of 3,060 to 6,000 feet would be from £325,000,-000 to £800,000,000 (the estimates growing with time), while to the end of 1927 the production had already reached £895,000,000 and the Rand had not passed its zenith. The further yield to be obtained from the existing mines was in 1925 put by Sir Robert N. Kotze (until lately the Government mining engineer of the Union of South Africa) as at least 310,000,000 tons from the end of 1924, which would be equal if one takes the yield at 28s per ton to £430,000,000. In 1927 Dr. H. Pirow, the present Government mining engineer, with £81,000,000 more taken out of the ground, put it at 327,000,000 tons (say £450,000,000) or more Unofficial estimates which allow for three new producers would put it much higher at £600,000,000 from the end of 1926, and this figure would give a total Rand output from the commencement of £1,450,000,000 Needless to say the actual output depends not merely on extensions of areas at present known to be payably auriferous, but upon conditions of work as depth is attained and especially upon working costs

It is more important to attempt to forecast the annual rate of gold production and this is especially difficult. As regards the Rand the average yield for the seven years to 1917 was 27s. 5d per ton and for the nine years following (omitting the exceptional year 1922) it averaged 28s. 3d, varying no more than between 27s. 10d and 28s 9d. annually, taking gold at its standard value Most estimates of the future rate of production refer to tonnage only, but this may be taken to yield 28s. per ton, the figure interpolated above. Sir Robert N. Kotze as far back as 1914 expected that for the then existing producers the yield would be £25,800,-000 per annum at the end of 1924 (while it was actually £39,-700,000 including some new producers), £17,600,000 at end—1929, £15,300,000 at end—1934, £11,700,000 at end—1939 and £7,900,-000 at end—1944 Writing on Sept. 30, 1925, he expected the yield from the then existing producers to be (if we take the yield at 28s, per ton) £31,000,000 in 1931, £21,000,000 in 1936 and £7,000,000 in 1941. Dr Pirow, writing on May 27, 1927, expected the yield (again translating his tons at 28s. apiece) to be £36,000,000 per annum at the end of 1934 and £20,000,000 at the end of 1939. A probable estimate, allowing for three probable new producers, would put it at £40,000,000 in 1930, £35,000,000 in 1935, £25,-000,000 in 1940 and £15,000,000 in 1945 Most of these estimates are based on the mines existing at the time they were made, and contain no allowance for additional areas taken up by those mines or for any increase in their rate of crushing—apart altogether from ignoring new producers. There are considerable areas on the Rand which may in course of time be worked, but except for the possible three new mines just mentioned they cannot at present be assessed Sufficient has been said to indicate that as time goes on the estimates increase, and this may be repeated. It is, however, clear that the West, Central and Middle-East Rand reached its zenith in 1912 with £32,700,000, while it at present contributes £20,500,000 and will probably continue to decline. On the other hand the Far East Rand—which is a vigorous growth of more recent date, taking its rise about 1904—has steadily advanced until it has reached over £21,000,000 and is likely to maintain this rate for many years to come. The Rand may shortly reach its zenith, though until quite recent years it seemed to have attained that point in 1916, when the world's output also was at its height.

It is not easy to assess the possibilities of the rest of the world, but on the whole its output is likely to decline. There are no outstanding goldfields outside the Rand The production of the United States, Australia and India is declining and that of Rhodesia and West Africa is stationary, while most hope of an increase is to be looked for especially in Canada, and possibly in Russia and Mexico. The world's output apart from that of the Rand was £63,000,000 in 1910, £59,100,000 in 1915, £35,200,000 in 1920, £41,300,000 in 1925, and £39,500,000 in 1927, the chief contributors to the decline being Australia and the United States, which together in 1910 yielded £33,200,000 and in 1927 only £12,-000,000. The present outlook is that the world's total may reach

£85,000,000 in 1930 and then decline to about £75,000,000 by 1940, unless some outstanding discovery is made. (J. Ki.)

SILVER

Any attempt to evaluate the world's resources in silver is complicated by the fact that so much of it is produced in connection with other metals, notably lead, copper and gold; almost every gold mine produces some silver and every silver mine some gold. The three largest silver-producing States of the United States are Utah, Montana and Idaho; in the first two silver is produced chiefly in connection with copper, and in the latter in connection with lead ores. About one-third of the silver in the United States is derived from what are primarily copper ores, one-third from lead ores and the remainder from all other kinds, including those which are simply silver ores. The silver content of many of these ores is so low that they could not possibly be worked for silver alone, so that an evaluation of silver resources becomes an estimation of the resources of copper, lead, zinc or other deposits which are important producers of silver.

Silver occurs in rocks of all geologic ages from the oldest to the most recent. It also occurs in nearly all countries of the world, so that nearly all of them are able to produce at least some part of their requirements. China, however, which is one of the principal silver-consuming countries of the world, produces very little silver, and it is not understood where its silver supply was obtained during its long isolation from the rest of the world. The available evidence as to the silver production of the countries with which it maintained contact does not indicate probable sources of supply. The Comstock lode in Nevada was discovered in 1858; by 1877 its annual production had reached $22,000,000 in silver, and for a long period this deposit furnished half the silver output of the United States, its total output of silver to 1900 being estimated at $220,000,000. Its output since 1886, when most of the deep mines in the lode were abandoned, has been relatively small. With the decline of the Comstock district the Leadville district in Colorado took its place as the greatest silver district of the world. Silver production there reached its peak (over $11,000,000) in 1881, followed by a gradual decline until 1907, since when it has remained at about $2,000,000 annually. The silver production of Canada was about 5,000,000 oz. per year until 1905, when the Cobalt district was discovered; in 1910–13 the output was over 32,000,000 oz. per year. Eight years later it was about 13,000,000 oz.; now it is over 20,000,000 annually. The average yearly production of the world for the period 1901–22 was 188,000,000 oz., ranging from 163,000,000 to 226,000,000. Mexico produces about one-third of the total; the United States about one-fourth, and Canada and South America each contribute about one-tenth of the total production.

The principal use of silver is in coinage, and the industrial arts. Photographic and chemical uses (which are the only ones in which silver may be said to be consumed) require an annual amount estimated at from 10,000,000 to 20,000,000 ounces. It is evident therefore that there are two reserves of silver, unmined ore and the accumulated stock of metal. It seems certain that the world can produce for a long period enough silver for the uses by which it is actually consumed. How long it can produce enough to supply needs for coinage and industrial arts depends not only on the discovery of new silver-producing districts, and the production of metals with which it is associated, but also to the extent to which silver coins may be replaced with token coins made of other more abundant metals. It is quite possible also that other metals may be substituted for silver in its uses in the industrial arts, since recent developments in the art of chromium plating and in the production of non-corrosive alloy steels make it possible to produce at a reasonable price metal articles that will not tarnish. It is possibly safe to imply that a silver-producing district like Cobalt will not be discovered anywhere except perhaps in northern Canada or parts of Africa and Siberia that have not been sufficiently explored. Consequently the principal additional supplies of silver for future use are likely to be copper, lead, zinc and other metal deposits where the large tonnage involved may yield considerable quantities even though the amount per ton is small. However, the copper deposits of Africa, which constitute the largest additions to the reserves of that metal which have recently been developed, contain no important silver reserves. (T. T. R.)

RARER ELEMENTS

Cobalt, molybdenum, titanium, tantalum, uranium and radium are treated here as representative of important classes of rare minerals, and nickel, vanadium and tungsten, properly termed rare minerals, are discussed separately above.

Cobalt.—Cobalt is found in small quantities in many places, and in large quantities in few. Its chief ores are smaltite ($CoAs_2$), and cobaltite ($CoAsS$). It is closely associated with nickel in occurrence, and has been found in meteorites and in a number of rare minerals, but these sources naturally play no very important rôle. The chief supply (1924–26) has been as follows: Queensland, Australia, furnishing about 100 tons of cobalt content in cobaltite concentrates; the Belgian Congo, about 825 tons of cobalt content in copper-iron-cobalt alloy; and Ontario, Canada, about 750 tons of cobalt content in alloys and chemicals. Arseno-sulphide ore from Chili, and cobalt-bismuth-nickel ores from Saxony, Germany, have added a few tons more of cobalt content, making a total of about 1,600–1,700 tons. During 1927 prospecting failed to reveal any new commercially important supplies, though some few prospects were located in Queensland, at Pola de Lena (Asturias), and in the Province of Leon. Shipments of ore from Cobalt, Ontario, in that year were reported as 7,309 tons, and of oxide metal and salts from the Union Minière du Haut Katanga as 350 tons. During the first nine months of 1928 the production from Ontario amounted to 460,995 lbs. of oxides, salts and unseparated oxides. The principal source in Ontario is high-grade silver ores and concentrates, averaging 5%–10% cobalt. These deposits and those of Africa seem to give an assurance of adequate supply. Some cobalt ores have been found in Norway, Sweden, the Caucasus, New Caledonia and at Lancaster Gap, Pennsylvania, U.S.A. During the last few years no cobalt has been produced in the United States. Other minerals containing cobalt are the sulphides linnaeite and jaipurite, the arsenides safflorite and skutterudite and the cobalt-copper sulphide carrollite.

Molybdenum.—The chief sources of molybdenum are molybdenite (MoS_2) and wulfenite ($PbMoO_4$). Molybdite ($Fe_2O_3 \cdot 3MoO_3 \cdot 7\frac{1}{2}H_2O$) and pateraite ($CoMoO_4$) are important sources. Molybdenum is rather widely distributed, having been found in Norway, Sweden, Finland, Saxony, France, Italy, Belgium, Spain, South Africa, Australia, New Zealand, Japan and Peru, but in recent years Canada and the United States have led in production. Early supplies, up to 1910, came chiefly from Queensland. By 1917 Canada was the largest producer, but of late the United States has been well in the lead. The ore at Climax, Colorado, carrying molybdenite and molybdite was said, in 1923, to be capable of producing 1,000 tons per day for 30 years, and this ore contains 11 lbs. of molybdenite per ton. In 1927 the United States was practically the only producer of molybdenum. Concentrates averaging 75%–88% MoS_2 amounted approximately to 2,150,000 lbs. This came principally from Climax, Colorado, and Sulphur Gulch, New Mexico. Although the consumption of molybdenum is increasing, the supply keeps well ahead of the demand, and a very recent statement shows that the area developed at Climax contains over 4,000,000 tons of ore. The present (1929) production is 3,000,000 lbs. of metallic molybdenum per annum. The recent considerable increase in the use of molybdenum has been due to its growing employment in machine and other steels, where great toughness is desired.

Tantalum.—Tantalum is closely associated with columbium or niobium and is found widely distributed in many rare-earth minerals, of which samarskite and euxenite are perhaps best known. The chief sources, however, are the minerals columbite and tantalite, two minerals which are identical except for the relative amounts of tantalum and columbium present. The general symbol representing their composition is $Fe,Mn(Cb,Ta)_2O_6$, and in various samples the ratio between the iron and manganese and the tantalum and columbium differs. In general, tantalite is high in tantalum and columbite in columbium. Some ores from Australia run as high as 50% to 70% Ta_2O_5. In the Black Hills of South Dakota and in Connecticut, U.S.A., ores have been

found ranging from 10% to 40% Ta_2O_5. Tantalum ores have also been reported from Maine, Massachusetts, New York, Pennsylvania, Virginia, North Carolina, Colorado and California in the United States, and from Norway, Sweden, Finland, Russia, Bavaria, Italy and the Malay States Between the years 1918 and 1926, about 17,500 lbs. of columbite were mined in the United States. Comparatively new uses of tantalum are in the manufacture of pen points and of radio tubes.

Titanium.—Titanium is very widely distributed. Its most important mineral sources are ilmenite ($FeTiO_3$) and rutile (TiO_2). F. W. Clarke, of the U.S. Geological Survey, stated some years ago that 784 out of 800 igneous rocks analyzed in the Survey laboratory contained titanium. During the years 1925–6 the production of ilmenite in metric tons was as follows: United States, 9,400; Norway, 4,150; Brazil, 3,000; Canada, 3,800; and India, 330; and the production of rutile from Norway and the United States was about 120 metric tons. The deposits of ilmenite ore at Lake Sanford, New York, and Iron Mountain, Wyoming, are estimated to contain many millions of tons, averaging 35% ilmenite The Titan Co of Norway owns one of the richest and largest known deposits of ilmenite. The Norwegian deposits of titanium in the islands of Lofoten and Vesterael, and near Rodsand and Solnordal, are very extensive. They are estimated still to contain about 500,000 tons, varying from 4%–40% TiO_2 Norway is estimated to have a total of 20–25 million tons of titanium minerals. In recent years the use of titanium oxide in pigments has been greatly developed and is now the chief use of titanium products. Its high covering-power and its non-poisonous and chemically inert properties are much in its favor.

Uranium and Radium.—It is best to discuss these elements together because of their close association. Practically all uranium minerals carry radium, and the world's supply of radium is produced from uranium minerals Uraninite or pitchblende, the chief uranium mineral, contains from 79% to 90% of the oxide U_3O_8 The composition of the mineral is very complex Carnotite is next in importance It is essentially a potassium-uranium vanadate ($K_2O \cdot 2UO_3 \cdot V_2O_5 \cdot 3H_2O$) carrying about 60% UO_3 There are many other uranium minerals, such as autunite, a calcium-uranyl phosphate, gummite, a lead-calcium-uranium silicate; tyuyamunite, a lime carnotite; uranocircite, a barium carnotite; betafite, a complex titano-columbo-tantalate of uranium, thorium and the rare earths, samarskite and euxenite, etc These uranium-radium ores are quite widely distributed, and the following figures, giving the world's estimated total production of radium up to and including the year 1926, in grams, give also an indication of the sources and production of uranium, since large quantities of its salts result as by-products of radium extraction. United States, 250; Belgian Congo, 180; Czechoslovakia, 42; Portugal, 15; Madagascar, 8; Russia (Ferghana), 6; Cornwall, 4, and South Africa, 1 In all, about 500 grams, valued at $70,000 per gram, have been produced The Belgian Congo in 1929 dominated the world market for radium The Union Minière du Haut Katanga sold 26 grams during the year ending June, 1928 The production obtained by the Soviet Government during the year was 6 grams, extracted from a Ferghana radium ore The Czechoslovakian Government is working ores mined at Jachymov, Joachimstal No radium was isolated in the United States during 1928, and only a small amount of radium ore was mined Katanga also furnishes the greater part of the uranium salts for the market. In general, it may be stated that the deposits in the Belgian Congo, together with those in Colorado, Utah, Arizona and New Mexico, U S A, will furnish an adequate supply of radium and uranium for years to come. At present about 28,000 lbs. of uranium pigments for glass are made annually

Zirconium.—The chief mineral sources of zirconium are zircon ($ZrSiO_4$), baddeleyite and brazilite, both essentially ZrO_2. Zircite is a commercial name given to the oxide or to a mixture of the silicate and the oxide. Zircon is found chiefly in Ceylon, the Ural Mountains, Greenland and Australia; and in the United States, in commercial quantities, in western North Carolina, at Ashland in Virginia and at Pablo Beach in Florida It occurs in small quantities associated with many minerals, notably with monazite sands. Baddeleyite, brazilite, zirkelite and zircite (the partially purified ore) come chiefly from Ceylon and Brazil. Exports from Brazil reached 1,119 tons in 1913, but fell off later. Recent information with regard to the amount of zirconium minerals used is lacking; in 1927, however, 4,488 lbs of zirconium was imported into the United States to supplement its supply Brazil is the world's main producer of zirconium ores. Zirconium ores are playing an important rôle in the manufacture of ceramics and refractories (P. E. B)

SUBSTITUTES FOR NATURAL RESOURCES

Any discussion of substitutes for natural resources must be prefaced by a discussion of the meaning of the term substitute. When whale oil was an important illuminant there was much concern as to its future supply and some search was made for possible substitutes The development of the petroleum industry arose principally from a desire to find a use, in order to provide a market, for an available material and not in response to a search for a whale oil substitute. The electric light, which has so largely displaced the oil lamp, was developed as a demand for something better, not as a demand for a petroleum substitute, for the market has been almost continuously over-supplied with petroleum during the whole period of electric lighting development It is therefore possible to think of chinaware and porcelain as substitutes for the vessels of wood, horn and metal that preceded them, of glass as a substitute for the oiled paper with which window openings were once closed, of wooden houses as a substitute for skin tents; and of brick houses as a substitute for wooden ones It is evident that these things are substitutes only in the sense that they replaced something that preceded them, and this because they better served some human need.

The term substitute has come to have a derived sense of something inferior used because that for which it is substituted either is not available in sufficient supply or, because of scarcity, is unduly high in price The idea of the inferiority of the substitute is one that would be cultivated by those engaged in the production and marketing of the original In the case of butter substitutes, for example, their production and sale are hampered by legislation which, it is alleged, represents the relative political strength of the interests involved rather than the scientific aspect of the matter The converse of this situation is presented by various devices which are sold to provide an artificial substitute for the therapeutic effect of sunlight; the producers of devices which give out infra-red rays are not required to furnish any evidence that the devices will produce the effects claimed for them It will therefore be clear that the economic and social problems involved in the use of substitutes are many and varied How difficult some of them are of solution can be illustrated by some examples. Suppose a necklace of artificial pearls so skilfully made that only a few of the most expert persons in the world would be able to detect that they were not real pearls, which would cost 10 or 100 times as much as the substitutes Has the belief in the inferiority of the substitute any other than a sentimental basis?

With inert natural resources the question is more easily determined because the purposes which natural resources serve can usually be set forth in exact chemical and physical specifications There can be no doubt whether one metal will conduct electricity as well as another, or whether one substance produces the same chemical effect as another for the kind and degree of difference can be measured, the cost can be ascertained, and the relation between the difference in the cost and the service studied But even in the case of these substances it is sometimes difficult to make a just evaluation A single substance may be used for a great many purposes, and thus is developed a tendency to carry over its known superiority for one use into another field where it may or may not be also superior The general considerations involved in this tendency are illustrated with specific examples Tin is mostly produced in south-eastern Asia and Bolivia, where there is little local use for it, while the United States, which uses over half the world's total output, produces none. About one-third of the metal imported into the United States is used for making tin-plate, and about two-thirds of the tin-plate is used for

making tin cans for packing various commodities. The principal use of tin cans is for preserved foods. It is easily possible to preserve food in ceramic ware jars, and many foods are sold in glass jars, but these jars are heavier and can easily be broken. For most purposes the glass jar is not, therefore, a satisfactory substitute for the tin can, but for specially selected fruits, which are to be sold at a high price, the glass jar is better, because the more attractive appearance of the jar is part of the consideration which enables it to be sold at a higher price. Thus glass is or is not a satisfactory substitute for tin in connection with food preservation, according to the special conditions attending its use

Tin-plate, in addition to being used for cans, is utilized for roofing purposes; obviously glass could not be so used. Terne plate (an alloy of lead and tin) is, however, used for roofing, but could not be used for food containers as the lead in the alloy produces toxic effects. Collapsible tubes made of tin are extensively used as containers for tooth-paste, shaving cream and various other commodities of a creamy consistence; no satisfactory substitute for tin has been devised for this purpose. Tin foil is used as a wrapping for candy and chewing gum, as a lining for boxes and cartons of cigarettes and for a variety of other purposes. Aluminium foil and lead foil are, to a growing extent, substitutes for this use, but neither has the bright lustre of tin foil. Except for appearance, paraffined paper would serve this use equally well. A variety of attractive transparent, moisture-proof and dust-proof wrapping materials have been placed on the market recently and, for some purposes, they are much better than tin foil, while for other uses they are inferior. Tin when alloyed with copper produces bronze, which has a variety of uses that it best serves. For some of these uses silicon or manganese can be used as the addition agent to the copper, but for others they are not satisfactory. When manufactured for transmission wire, cadmium can be used, with better results than other substances from the transmission standpoint, although not from other considerations. Tin is also used in the alloys employed for bearings in machinery. These alloys are of great variety, depending on the service required of them, and a discussion of possible substitutes would be exceedingly complex. Tin has a variety of chemical uses, two of the most important being for making enamels and weighing silk. In both cases the use of substitutes is possible

For tin, therefore, various things may be used as substitutes in its various uses, with variable degrees of effectiveness, according to the circumstances of each case No one can safely prophesy that research will not reveal some substitute that will give equally good service at equal or even less cost and, on the other hand, no one can safely prophesy that it will. The whole subject of substitutes is charged with uncertainty from its very nature In the search for substitutes several general considerations must be maintained as objectives. The first is that the substitute should be more abundant than that which it replaces; little advantage is gained if a sufficient supply of the substitute material is not available. A second is that the substitution should be real, not fictitious; large quantities of power or of other materials should not be generally involved in making the substitution. Substitutes should, if possible, be locally available, to avoid the burden of transportation cost, and also to avoid the possibility of being dependent on foreign countries for a source of supply. Finally, the substitute should not impose too heavy a task in changing the habits of consumers, or the usual processes of plant operations.

The principal use of manganese is in connection with steel manufacture and for this purpose an alloy containing 80% manganese is usually employed. In America manganese ore of the desired quality has to be imported; domestic ores can be used to make a 20% alloy but less conveniently, as the 20% alloy has to be added while molten, although solid lumps of the 80% alloy that can be employed are commonly used. Substitution of the lower grade alloy is made difficult by this consideration.

Substitutes for gasolene have been much discussed and alcohol is one of the various materials that have been proposed It has the great advantage that it can be made from vegetable materials that are reproducible Alcohol cannot, however, be used effectively in an engine built to use gasolene; it needs one specially designed for it. Its general use as a substitute would therefore involve not only the organizing of industry to produce and distribute the alcohol, but also the replacement of over 20,000,000 gasolene engines. Another possible substitute is gasolene made from oil shale. To mine the shale required to produce any considerable part of the gasolene now used would require the setting up of a mining industry of approximately the same size as our present coal-mining industry, and this industry would have to be in regions that are now very sparsely inhabited because they are arid Thus not only a shifting of population would be required, but also the provision for water and food supply, housing and other facilities. The task is thus much more complex than the working out of a process whereby gasolene can be made from oil shale.

Substitution of one product for another not only involves the various considerations outlined above, but often requires the finding of adequate markets for by-products. Much has been said about the wastefulness of buying coal in its raw state, and one of the principal subjects for research is the processing of coal to yield coke, gas and a great variety of by-products. The proportions of these various things that can be made are definitely fixed by chemical and engineering considerations, but the markets for them are quite variable, not only from day to day, but over longer periods. The demand for gas may be greater than the demand for the coke produced, or it may be less, and these relations may shift from day to day or week to week. For a time it was difficult to find adequate outlet for the benzol made as a by-product, and it was chiefly used as a substitute for gasolene. However, development of the nitro-cellulose lacquers provided a large demand for benzol at an increased price, and the present supply was in 1929 practically all used for this purpose.

The problems involved in considering substitutes for things which are the result of life processes are even more complex. Citing clothing as an example, changes in human habits and considerations of style are extremely important. Only a few years ago wool and cotton were the principal materials from which articles of clothing were made, but in recent years demands have been transferred so largely to silk and fur that the woollen and cotton textile industries have been seriously affected Straw, ribbon and other materials were formerly used extensively in making women's hats, but now felt hats are almost universal. To what extent demands for materials may be affected by a change in styles which may be brought about by skilful advertising and merchandising is exceedingly difficult to prophesy. Such changes have some limits imposed by physical conditions; thus wool is used for men's outer garments, because they keep their shape better.

In food products the tendency has been steadily to increase the number, variety and quality over a long period of years, with the result that people are now better nourished than at any previous period in human history. Fruit, for example, instead of being available to only the wealthier class outside the growing season is now a regular article of diet in almost every home all the year round; its greater consumption, it is believed, has led to a decline in the per capita consumption of meat. Sugar and chocolate are also used much more extensively than formerly; these, like most other food products, seem capable of being produced in any amounts that are required. Chewing gum, though not a food, is, however, an example of an organic product for which it may be necessary to find a substitute, as its increasing use bids fair to outstrip the present supply of chicle gum (the principal ingredient), which is the only gum that at the temperature of the mouth is neither too soft nor too hard, and is also free from any objectionable flavour. Rubber illustrates the manner in which public concern over supply of raw materials varies. The demand for rubber was easily met, until the introduction of the automobile forecast a great increase. This caused much concern for future supply and many chemists have worked to discover substitutes. The great increase in rubber production in Malaya shifted attention to schemes to maintain the price of the raw material in the face of production that had increased faster than consumption. If anything equally serviceable can be produced and sold at less cost it will be adopted, but the world

can produce what is needed without necessity for any substitutes.

Raw material for paper manufacture has long been a source of concern. Different materials are used to produce the various grades of paper, but newsprint, which is the largest in demand, is made from wood pulp. For the purpose soft woods are required, and these woods are also the principal kind needed for lumber purposes. Neither newsprint nor lumber has much salvage value and they are largely destroyed by their first use. Some progress has been made in decreasing the demands on lumber for packages, and it has also been found possible to remove the ink from newspapers, though not sufficiently to permit the re-use of the stock for the same purpose It seems probable that wood and all the other raw materials that are produced as a result of growth can, with care, always be produced in sufficient amounts to meet human needs, so that the problem is really one of producing them at a cost which will not produce some economic shift that disturbs the complex equilibrium in modern industry. Shifts of this sort result from so many other causes in addition to shortage of essential raw materials and human ingenuity has been so successful in meeting them thus far that while the study of substitutes is proper for the engineer and chemist, it does not at present need to be a matter of great public concern.

(T. T R)

PHYSICAL UNITS. In order that our acquaintance with any part of nature may become exact we must have not merely a qualitative but a quantitative knowledge of facts Hence the moment that any branch of science begins to develop to any extent, attempts are made to measure and evaluate the quantities and effects found to exist To do this we have to select for each measurable magnitude a *unit* or standard of reference, by comparison with which amounts of other like quantities may be numerically defined There is nothing to prevent us from selecting these fundamental quantities, in terms of which other like quantities are to be expressed, in a perfectly arbitrary and independent manner, and, as a matter of fact, this is what is generally done in the early stages of every science. We may, for instance, choose a certain length, a certain volume, a certain mass, a certain force or power as our units of length, volume, mass, force or power, which have no simple or direct relation to each other. Similarly we may select for more special measurements any arbitrary electric current, electromotive force, or resistance, and call them our units The progress of knowledge, however, is greatly assisted if all the measurable quantities are brought into relation with each other by so selecting the units that they are related in the most simple manner, each to the other and to one common set of measurable magnitudes called the *fundamental quantities*

The progress of this co-ordination of units has been greatly aided by the discovery that forms of physical energy can be converted into one another, and that the conversion is by definite rule and amount (*See* ENERGY) Thus the mechanical energy associated with moving masses can be converted into heat, hence heat can be measured in mechanical energy units The amount of heat required to raise one gramme of water through 1° C in the neighbourhood of 10° C is equal to about 42 million *ergs*, the *erg* being the kinetic energy or energy of motion associated with a mass of 2 grammes when moving uniformly, without rotation, with a velocity of 1 cm per second This number is commonly called the "mechanical equivalent of heat," but would be more exactly described as the "mechanical equivalent of the specific heat of water at 10° C." Again, the fact that the maintenance of an electric current requires energy, and that when produced its energy can be wholly utilized in heating a mass of water, enables us to make a similar statement about the energy required to maintain a current of one ampere through a resistance of one ohm for one second, and to define it by its equivalent in the energy of a moving mass. Physical units have therefore been selected with the object of establishing simple relations between each of them and the fundamental mechanical units. Measurements based on such relations are called *absolute measurements.* The science of dynamics, as far as that part of it is concerned which deals with the motion and energy of material substances, starts from certain primary definitions concerning the measurable quantities involved In constructing a system of physical units, the first thing to consider is the manner in which we shall connect the various items. What, for instance, shall be the unit of force, and how shall it be determined by simple reference to the units of mass, length and time?

The modern absolute system of physical measurement is founded upon dynamical notions, and originated with C. F. Gauss. The postulate which lies at the base of the study of physics is that in the ultimate issue we can describe all phenomena in terms of mechanical data Our fundamental scientific notions are those of *length, time,* and *mass* Hence, in selecting units for physical measurements, we have first to choose units for the above three quantities.

Fundamental Units.—Two systems of fundamental units are in common use. the British system, having the yard and pound as the standard units of length and mass, frequently termed the "foot-pound-second" (F P S) system; and the "centimetre-gramme-second" system (C G S.), having the centimetre and gramme as standard units of length and mass, termed the "metric" system The fundamental unit of time is the same in both systems, namely, the "mean solar second," 86,400 of which make one solar day (*See* TIME.) Since these systems and the corresponding standards, together with their factors of conversion, are treated in detail in the article WEIGHTS AND MEASURES, we need only deal here with such units as receive special scientific use, *i e.*, other than in ordinary commercial practice Various secondary units are chosen for special purposes. In astronomy, where immense distances have to be very frequently expressed, a common unit is the mean radius of the earth's orbit, the "astronomical unit" of length, *i e.*, 92,900,000 miles For stellar distances astronomers have adopted a unit of length termed the "light year," which is the distance traversed by light in a year; this unit is 63,000 times the mean radius of the earth's orbit. Another unit employed is the par-sec, that is, the distance at which the value of the parallax is one second of arc. For very small lengths, such as the wave lengths of light, the unit selected is a ten-thousand-millionth of a metre, termed an Ångström unit or a "tenth-metre," since it is 10^{-10} metres. Sometimes the thousand-millionth of a metre, the "micromillimetre," denoted by $\mu\mu$, or again the "micron," denoted by μ and equal to one-millionth of a metre is employed. The latter is much used by bacteriologists.

Units in Mechanics.—The quantities to be measured in mechanics (*q v.*) are velocity and acceleration (dependent on the units of length and time only), momentum, force, energy or work and power, dependent on the three fundamental units The unit of velocity in the British system is 1 foot. Similarly, the unit on the metric system is 1 centimetre per second Momentum is defined as the product of mass into velocity; unit momentum is therefore the momentum of unit mass into unit velocity; in the British system the unit of mass is the pound, and in the metric system, the gramme is the unit of mass

Force, being measured by the change of momentum in unit time, is expressed in terms of the same units in which unit momentum is defined The natural British unit is the "poundal," the force which in one second accelerates the velocity of a mass of one pound by one foot per second; but it has not come into general use The metric (and scientific) unit, named the "dyne," is derived in the same way from the centimetre, gramme, and second. The poundal and dyne are related as follows:—1 poundal = 13,825·5 dynes.

A common unit of force among engineers is the "weight of one pound," by which is meant the force equivalent to the gravitational attraction of the earth on a mass of one pound. This unit obviously depends on gravity; and since this varies with the latitude and height of the place of observation (*see* EARTH, FIGURE OF), the "force of one pound" of the engineer is not constant. Roughly, it equals 32·17 poundals A pressure is a force per unit area and can be measured in terms of the above units; for example, as lb. wt per square foot. The standard atmosphere (corresponding to a barometric height of 760 cm.) is often taken as a secondary unit; it is equal to 1,013,600 dynes per centimetre.

Energy or work is measured by force acting over a distance. The scientific unit is the "erg," which is the energy expended when a force of one dyne acts over 1 centimetre. (*See* ENERGY.) This unit is too small for measuring the quantity of energy associated, for instance, with engines; for such purposes a unit ten million times as great, termed the "joule," is used. As we noticed in the case of units of force, common-life experience has led to the introduction of units dependent on gravitation, and therefore not invariable; the common British practical unit of this class is the "foot-pound"; in the metric system its congener is the "kilogramme-metre."

Power is the rate at which force does work; it is therefore expressed by "units of energy per second." The metric unit in use is the "watt," being the rate equal to 1 joule per second. Larger units in practical use are: "kilowatt," equal to 1,000 watts; the corresponding energy unit being the kilowatt-second, and 3,600 kilowatt-seconds or 1 kilowatt-hour called a "Board of Trade unit" (B.T.U.). This last is a unit of energy, not power. In British engineering practice the common unit of power is the "horse-power" (HP), which equals 550 foot-pounds performed per second, or 33,000 foot-pounds per minute; its equivalent in the metric system is taken as 746 watts.

Units of Heat.—In studying the phenomena of heat, two measurable quantities immediately present themselves:—(1) temperature and (2) quantity of heat. Three arbitrary scales are in use for measuring temperature (*see* THERMOMETRY), and each of these scales affords units suitable for the expression of temperature. On the Centigrade scale the unit, termed a "Centigrade degree," is one-hundredth of the interval between the temperature of water boiling under normal barometric pressure (760 mm. of mercury) and that of melting ice; the "Fahrenheit degree" is one-hundred-and-eightieth, and the "Réaumur degree" is one-eightieth of the same difference.

Empirical units of "quantity of heat" readily suggest themselves as the amount of heat necessary to heat a unit mass of any substance through unit temperature. In the metric system the unit, termed a "calorie," is the quantity of heat required to raise a gramme of water through one degree Centigrade. This quantity, however, is not constant, since the specific heat of water varies with temperature. (*See* CALORIMETRY.) In defining the calorie, therefore, the particular temperatures must be specified; consequently there are several calories particularized by special designations:—(1) gramme-calorie, the heat required to raise 1 gramme of water between 15° C and 17° C through 1° C; (2) "mean or average gramme calorie," one-hundredth of the total heat required to raise the temperature of 1 gramme of water from 0° C to 100° C; These units are thus related:—1 common calorie = 0·987 mean calories = 0·992 zero calories. A unit in common use in thermo-chemistry is the *greater calorie,* which refers to one kilogramme of water and 1° C. In the British system the common unit, termed the "British Thermal Unit" (B.Th.U.), is the amount of heat required to raise one pound of water through one degree Fahrenheit; a centigrade unit (C.H.U.) has also been introduced and is rapidly being adopted.

Electrical Units.—We are principally concerned in electrical work with three quantities called respectively, electric current, electromotive force, and resistance. These are related to one another by Ohm's law, which states that the electric current in a circuit is directly as the electromotive force and inversely as the resistance, when the current is unvarying and the temperature of the circuit constant. Hence, if we choose units for two of these quantities, the above law defines the unit for the third. Much discussion has taken place over this question. From the scientific standpoint the current and voltage are most readily defined in terms of forces. The ampere is defined as one-tenth of that current which, flowing in a circle of 1 cm. radius, exerts a force of 2π dynes upon a unit magnetic pole placed at its centre. This unit pole is itself defined in terms of the mechanical force between two such poles; so the ampere is made to depend on mechanical units. Again, voltage × current × time is mechanical work and is expressed in terms of ergs or joules. Resistance is voltage divided by current, and thus the corresponding unit of resistance is defined. But for electric engineering (power and light) the choice is decided by the nature of the quantities themselves. Since resistance is a permanent quality of a substance, it is possible to select a certain piece of wire or tube full of mercury, and declare that its resistance shall be the unit of resistance and if the substance is permanent we shall possess an unalterable standard or unit of resistance. For these reasons the practical unit of resistance, now called the international ohm, has been selected as one of the above three practical electrical units.

It is known that there are two available methods for creating a standard or unit electric current. If an unvarying current is passed through a neutral solution of silver nitrate it decomposes or electrolyses it and deposits silver upon the negative pole or cathode of the electrolytic cell. According to Faraday's law and all subsequent experience, the same current deposits in the same time the same mass of silver. Hence we may define the unit current by the mass of silver it can liberate per second. Again, there is the method already described. Thirdly, the unit of electromotive force may be defined as equal to the difference of potential between the ends of the unit of resistance when the unit of current flows in it.

Apart, however, from the relation of these electrical units to each other, it has been found to be of great importance to establish a simple relation between the latter and the absolute mechanical units. Thus an electric current which is passed through a conductor dissipates its energy as heat, and hence creates a certain quantity of heat per unit of time. Having chosen our units of energy and related unit of quantity of heat, we must so choose the unit of current that when passed through the unit of resistance it shall dissipate 1 unit of energy in 1 unit of time.

British Association Units.—The founders of the modern system of practical electrical units were a committee appointed by the British Association in 1861, at the suggestion of Lord Kelvin, which made its first report in 1862 at Cambridge. (See *B. A. Report.*) The five subsequent reports containing the results of the committee's work, together with a large amount of most valuable matter on the subject of electric units, were collected in a volume edited by Prof. Fleeming Jenkin in 1873, entitled *Reports of the Committee on Electrical Standards.* This committee continued to sit and report annually to the British Association since that date until 1912; the whole of the reports have since been reprinted in book form. It is to the labours of this committee, acting in friendly correspondence with international committees, that the present system of electrical measurements is due.

Electrostatic and Electromagnetic Units.—It has throughout been recognized that a second consistent system of electrical units is possible. The unit electrical charge (or quantity of electricity) can be based upon the force between two electric charges. Accordingly, on the *electrostatic* system the unit of electric quantity is such that $f = q^2/(Kd^2)$ where q is the quantity of each of two equal charges, d is the distance between them and K is the dielectric constant (or specific inductive capacity) of the intervening medium, that of air being taken as unity. (*See* ELECTROSTATICS.) The current is then defined as the amount that flows in unit time, and the energy is specified in terms of ergs or joules; thence the unit of resistance is defined by means of the equation Energy $= RC^2t$. The relation between the electromagnetic and electrostatic system of units is that the absolute EMU unit of current (*i.e.,* 10 amperes) is equal to 3×10^{10} electrostatic units. (*See* the various articles on ELECTRICITY.)

Practical Electric Units.—The committee of the British Association charged with the duty of arranging a system of absolute and magnetic units settled also on a system of practical units of convenient magnitude, and gave names to them as follows:—

10^9 absolute	electromagnetic		units of resistance	= 1 ohm
10^8	„	„	units of electromotive force	= 1 volt
$\frac{1}{10}$th of an	„	„	unit of current	= 1 ampere
$\frac{1}{10}$th of an	„	„	unit of quantity	= 1 coulomb
10^{-9}	„	„	units of capacity	= 1 farad
10^{-15}	„	„	units of capacity	= 1 microfarad

Since the date when the preceding terms were adopted, other multiples of absolute C.G.S. units have received practical names, thus:—

10^7 ergs or absolute C.G.S. units of energy	= 1 joule
10^7 ergs per second or C.G.S. units of power	= 1 watt
10^9 absolute units of inductance	= 1 henry
10^8 absolute units of magnetic flux	= 1 weber
1 absolute unit of magnetomotive force	= 1 gauss

(Neither the weber nor the gauss has received very general adoption, although recommended by the committee of the British Association on Electrical Units. Many different suggestions have been made as to the meaning to be applied to the word "gauss." The practical electrical engineer, up to the present, prefers to use *one ampere-turn* as his unit of magnetomotive force, and *one line of force* as the unit of magnetic flux, equal respectively to $10/4\pi$ times and 1 times the C.G.S. absolute units. Very frequently the "kiloline," equal to 1,000 lines of force, is now used as a unit of magnetic flux.)

An Electrical Congress was held in Chicago, U.S.A., in Aug. 1893, to consider the subject of international practical electrical units, and the result of a conference between scientific representatives of Great Britain, the United States, France, Germany, Italy, Mexico, Austria, Switzerland, Sweden and British North America, after deliberating for six days, was a unanimous agreement to recommend the following resolutions as the definition of practical international units. These resolutions and definitions were confirmed at other conferences, and at the last one held in London in Oct. 1908 were finally adopted. It was agreed to take:—

"As a unit of resistance, the *International Ohm*, which is based upon the ohm equal to 10^9 units of resistance of the C.G.S. system of electromagnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass, of a constant cross-sectional area and of the length of 106·3 cm.

"As a unit of current, the *International Ampere*, which is one-tenth of the unit of current of the C.G.S. system of electromagnetic units, and which is represented sufficiently well for practical use by the unvarying current which, when passed through a solution of nitrate of silver in water, deposits silver at the rate of 0·00111800 of a gramme per second.

"As a unit of electromotive force, the *International Volt*, which is the electromotive force that, steadily applied to a conductor whose resistance is one international ohm, will produce a current of one international ampere. It is represented sufficiently well for practical purposes by $\frac{10,000}{10,184}$ of the E.M.F. of a normal or saturated cadmium Weston cell at 20° C, prepared in the manner described in a certain specification.

"As a unit of quantity, the *International Coulomb*, which is the quantity of electricity transferred by a current of one international ampere in one second.

"As the unit of capacity, the *International Farad*, which is the capacity of a condenser charged to a potential of one international volt by one international coulomb of electricity. (This unit is far too large for most purposes; one millionth of it is called a microfarad; even a millionth of this is more practical in certain modern applications—it might be called a micro-microfarad or a dimicrofarad, on the analogy of the use of di- in chemical nomenclature.)

"As a unit of work, the *Joule*, which is equal to 10^7 units of work in the C.G.S. System, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampere in an international ohm.

"As a unit of power, the *Watt*, which is equal to 10^7 units of power in the C.G.S. System, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

"As the unit of inductance, the *Henry*, which is the induction in a circuit when an electromotive force induced in this circuit is one international volt, while the inducing current varies at the rate of one ampere per second."

Rational System of Electrical Units.—The above-described practical system based on the C.G.S. double system of theoretical units labours under several very great disadvantages. The practical system is derived from and connected with an abnormally large unit of length (the earth quadrant) and an absurdly small unit of mass. Also in consequence of the manner in which the unit electric quantity and magnetic pole strength are defined, a coefficient, 4π, makes its appearance in many practical equations. For example, on the present system the magnetic force H in the interior of a long spiral wire of N turns per centimetre of length when a current of A amperes circulates in the wire is $4\pi AN/10$. Again, the electric displacement or induction D through a unit of area is connected with the electric force E and the dielectric constant K by the equation $D=KE/4\pi$. In numerous electric and magnetic equations the constant 4π makes it appearance where it is apparently meaningless. A system of units in which this constant is put into its right place by appropriate definitions is called a rational system of electric units. Several physicists have proposed such systems.

Heaviside's Rational System.—One remedy for the difficulty has been suggested by Heaviside. He proposes to restate the definition of a unit magnetic pole in such a manner as to remove this constant 4π from the most frequently employed equations. His starting-point is a new definition according to which a unit magnetic pole is said to have a strength of m units if it attracts or repels another equal pole placed at a distance of d centimetres with a force of $m^2/4\pi d^2$ dynes. It follows from this definition that a rational unit magnetic pole is weaker or smaller than the irrational or British Association unit pole in the ratio of $1/\sqrt{4\pi}$ to 1, or ·28205 to 1. The magnetic force due to a rational pole of strength m at a distance of d centimetres being $m/4\pi d^2$ units, if we suppose a magnetic filament having a pole of strength m in rational units to have a smaller sphere of radius r described round its pole, the magnetic force on the surface of this sphere is $m/4\pi r^2$ units, and this is therefore also the numerical value of the flux density. Hence the total magnetic flux through the surface of the sphere is

$$4\pi r^2 \times m/4\pi r^2 \text{ units} = m \text{ units};$$

and therefore the number which denotes the total magnetic flux coming out of the pole of strength m in rational units is also m.

It follows, therefore, that if the intensity of magnetization of the magnetic filament is I and the section is s, the total flux traversing the centre of the magnet is Is units; and that if the filament is an endless or poleless iron filament magnetized uniformly by a resultant external magnetic force H, the flux density will be expressed in rational units by the equation $B=I+H$. The physical meaning of this equation is that the flux per square centimetre in the iron is simply obtained by adding together the flux per square centimetre, if the iron is supposed to be removed, and the magnetization of the iron at that place.

A final question suggests itself: Do the systems of units founded directly upon mechanical quantities constitute finality, or can we proceed to make a further reduction in the number of primary quantities?

There are certain constants of nature which are fundamental, invariable, and, as far as we know, of the same magnitude in all parts of the universe. One of these is the *mass* of the atom, say of hydrogen. Another is the *length* of a wave of light of particular refrangibility emitted by some atom, say one of the two yellow lines in the spectrum of sodium or one of the hydrogen lines. Also a *time* is fixed by the velocity of light in space which is according to the best measurement very close to 3×10^{10} cms. per sec. Another natural unit is the so-called *constant of gravitation*, or the force in dynes due to the attraction of two spherical masses each of 1 gramme with centres at a distance of 1 cm. Very approximately this is equal to 648×10^{-10} dynes. Another natural electrical unit of great importance is the electric charge represented by 1 electron. (*See* ELECTRICITY.) This, according to the latest determination, is nearly $3{\cdot}4\times10^{-10}$ electrostatic units of quantity on the C.G.S. system. Hence, 2,930 million electrons are equal to 1 E.S. unit of quantity on the C.G.S system, and the quantity called 1 coulomb is equal to 879×10^{16} electrons. In round numbers 9×10^{-18} electrons make 1 coulomb. The electron is nature's unit of electricity and is the charge carried by 1 hydrogen ion in electrolysis. (*See* CONDUCTION, ELECTRIC, sec. *Liquids*.) Accordingly a truly natural system of physical units

would be one which was based upon the electron, or a multiple of it, as a unit of electric quantity, the velocity of light or fraction of it as a unit of velocity, and the mass of an atom of hydrogen or multiple of it as a unit of mass. An approximation to such a natural system of electric units will be found discussed in chap. 17 of a book on *The Electron Theory*, by E. E. Fournier d'Albe (London, 1906), to which the reader is referred. In addition, in more recent times, a new universal constant has been determined. It is generally known as Planck's constant because it first appeared in Planck's theory of full radiation.

PHYSICS. The old term "natural philosophy" signified an attempt to frame a theory of that part of the material universe which could be explored by observation and experiment, and of which the underlying laws were sufficiently understood to be amenable to mathematical calculation. The science of biology was excluded from its purview, for life was not sufficiently understood to be amenable to treatment of that thorough kind, and similarly the mental sciences were excluded, although an observable material organism was a sensible instrument and mode of manifestation; but even so the subject was a huge one and had to be subdivided. The branch of biological science nearest to inclusion was physiology, being a study of the mechanism involved in the functions of living organisms.

The branch of natural philosophy that advanced most rapidly towards perfection was the mechanics of the heavenly bodies, where the things treated of were comparatively few and far apart, and could readily be dealt with as individuals, so that the laws governing their movements could be formulated with some satisfaction. This branch, under Sir Isaac Newton, became so highly elaborated as to dominate and set an example to the rest; but, after all, astronomy was only a special case of the motion of material bodies, and Galileo had begun the study of ordinary motions on the earth's surface, developing into a complete treatment of their velocities, accelerations and distortions, and partly accounting for them by the fundamental inertia of matter influenced by forces of different kinds, and by the subsidiary properties of elasticity, friction, cohesion and the like.

Matter was always known to exist in three states, solid, liquid and gaseous, each having peculiar properties of its own; and the fluids formed resisting media through which the solids could move. Moreover all these bodies were subject, not only to locomotion in bulk, but to internal vibrations, and for the apprehension of these vibrations we had special sense organs, which enabled them to be examined with special facility, and thereby taught us much concerning the things themselves. Some of these vibrations are known as sound, others as heat, and there was yet a third kind of vibration, appealing to the eye, the effect of which could travel across space empty of matter, which therefore had to be filled with a hypothetical substance called "the ether" (or aether), whose properties are still in doubt.

Apart from these vibrations, which could be originated and absorbed by matter, it was found that matter consisted of particles called atoms, of a definite size and weight, which could enter into combination with each other, and so form the various compounds with which humanity had always been acquainted. A study of this branch of natural philosophy blossomed into the great science of chemistry, while geology took over a study of the history and conditions of the earth's crust. The remaining portions of natural philosophy were grouped in comparatively modern times under the head *physics*, which, by derivation from φύσις, signifies a study of nature so far as it can be reduced by calculation and experiment to a few simple or at least fundamental laws. Those laws, first studied by Galileo, were formulated with masterly precision by Isaac Newton, and throughout the 19th century dominated the field. It was hoped at one time that they would be all-inclusive; the expressed ambition of Newton was that ultimately all observable phenomena might be brought under their sway. A long continued effort was made throughout the 19th century to apply them, not only to matter, but to the ether also—an attempt which failed, and has now, for a time at any rate, been abandoned. Hypothetical attempts were also made to include the phenomena of life and mind under the same fundamental laws of mechanism, without necessarily postulating anything outside and beyond such treatment; these efforts, the basis of a materialistic philosophy, were perfectly legitimate, though they have proved unsuccessful. No one claims that the ordinary laws of physics and chemistry are disobeyed by live things, but it is now fairly admitted that they have to be supplemented, while, with regard to the ether, it is still a question as to how far the simple laws are applicable at all. The very terms inertia, velocity, acceleration, force, are of only doubtful validity except when applied to definite material particles, and even then these properties themselves require elucidation. It may be that no fundamental explanation of even the simplest phenomenon can be satisfactorily and safely given until the laws of the fundamental substance, of which probably matter itself is composed, are better understood and formulated.

The Sub-divisions of Physics.—Meanwhile the science of physics has made gigantic strides, throwing off such branches as sound, light, heat, elasticity, hydrodynamics and the kinetic theory of gases. It was found that, although the atoms of matter were too small to be dealt with individually, the results of their combined action could be formulated statistically, in accordance with the laws of probability; and that, although the atoms of a gas were flying about in all directions at random, yet their number was so great that the pressure on any surface exposed to their random bombardment could be treated as perfectly uniform, except indeed when the exposed surface was extremely small. In the latter case individual atoms might exert a noticeable effect, giving occasionally a one-sided bombardment, and exerting an otherwise inexplicable propelling action on the body exposed to it. Thus originated a discrimination, now universally recognized, between the peculiar activities displayed by very small things and the customary behaviour of things on so large a scale that we can handle and directly apprehend them by our senses.

So far as matter was concerned there seemed little difference between physics and chemistry, except that physics sought to probe into the deeper-seated motions underlying molecular combination, and to investigate not only the anatomical groupings but the actual working of the agencies which rendered those groupings possible. It sought to understand the hidden meaning of chemical affinity and the nature of cohesion generally, and indeed of gravitation too. It was not satisfied with the idea of forces acting at a distance, or of the mere clinging together of polarized particles; it sought to dive down into the hidden meaning of attraction, and to explain if possible the very atoms themselves.

In all this it was mightily helped by the development—since Newton's time, in fact mainly in the 19th century—of two great and important new branches, the sciences of electricity and magnetism. These are agents which, like light, operate through what we call empty space or vacuum, and therefore seem primarily associated not with matter as such, but with the more fundamental ether. The fact that mankind has no sense organ for their direct appreciation involved the consequence that, unlike sound, light and heat, they had to be discovered as well as critically examined and studied. Nevertheless in our own time these new powers have become dominant; they have been taken up by engineers, and applied on an extensive and beneficent scale, so that they are now more or less familiar to everybody. The applications of electricity and magnetism are of great and growing importance, but that is not what constitutes their vivid interest to a physicist. Their importance is that they give a clue and greatly extend our

knowledge of the properties of the ether, which had only very partially been displayed in the familiar form of light. Indeed, Clerk Maxwell, perhaps the greatest man of science in the 19th century, made the far reaching discovery that light itself was an electromagnetic vibration, a fact which has now blossomed into the engineering application of radio telegraphy.

The phenomenon called radiation, of which visible light is one small portion, contains the key to the interaction between ether and matter, and is the link between the physics of the 19th and that of the 20th century. All matter is always radiating, and if it does not cool or otherwise lose energy it is only because it absorbs exactly the quantity and quality which it emits. Stagnation of any kind is non-existent in the material universe. Every particle quivers, and the ether quivers in sympathetic unison. The problem of their interaction is being attacked and partially solved by the mathematical physicists of the 20th century.

It may be asked, indeed it often is asked, how discoveries can be made by means of calculation. The answer is quite definite. The mathematical physicist probes down into the fundamental activities, so as to be able to formulate in his mind what is really going on, and to express the actions which can be observed in a definite and quantitative form called an equation, especially in that form called a differential equation, which expresses interactions among the smallest parts. The discovery of the relation between electricity and magnetism on the one hand, and light on the other, will serve as an illustration of the process. Clerk Maxwell took the known phenomena of electricity and the known phenomena of magnetism, together with their interaction so brilliantly discovered and examined by the early physicists of all countries at the beginning of the 19th century culminating in the work of Faraday, and threw them into the form of equations. These, when combined and manipulated in accordance with the laws of pure mathematics, resulted in a differential equation in time and space, containing nothing but electric and magnetic quantities, which nevertheless corresponded with the known equation for waves, such as those of sound or of light or on the surface of water. He perceived therefore that electromagnetic experiments could in the future probably give rise to such waves, and that they would travel at a speed which could be calculated in terms of the electric and magnetic constants of a vacuum, *i.e.*, of the ether. He inaugurated a set of experiments which would determine, not indeed those constants separately, for they are still unknown, but their product, viz., the product which appeared in his differential equation as determining the speed of the waves. He found that the velocity with which his waves ought to travel was identical with that of light, and thus came to the conclusion, and was ultimately held to prove for all time, that light was an electromagnetic phenomenon. On this basis a whole new development began, and continues to this day.

Applications of Differential Equations.—It is worth while illustrating the bearing of a differential equation, and the way in which it embodies a whole series of phenomena which can be dissected from it by the arts of pure mathematics in a purely mechanical though recondite manner, and then handed back to the physicist for interpretation. Naturally the physicist and the mathematician may be combined in the same individual in exceptional cases, and as has recently been said (*Nature*, May 26, 1928): "It is interesting to speculate whether the intellectual gulf separating the great physical scientists from the rest of their fellows is not greater now than at any previous period in the world's history—whether they have not usurped the place of the metaphysicians." That was true in Newton's day, and is true now; though no one claims that any single individual possesses the exceptional power displayed by Newton.

A differential equation which may serve as an illustration is the following:

$$A\frac{d^2H}{dt^2} + B\frac{dH}{dt} = C\left(\frac{d^2H}{dx^2} + \frac{d^2H}{dy^2} + \frac{d^2H}{dz^2}\right).$$

H is any quantity, no matter what, representing some salient feature in the kind of subject dealt with; it is allowed to have a slope of variable gradient in any of the three directions in space, and to have a rate of variation and indeed an accelerated or variable rate of variation in time. The equation expresses the relation between these extremely abstract possibilities as affecting the (perhaps unknown) quantity *H*, while *A*, *B*, *C* are physical constants characteristic of the special conditions appropriate to some particular problem, each being capable of a physical interpretation in any definite case.

When the conditions are such that *A* is zero, the equation can be made to represent the whole theory of the conduction of heat; and it was thus worked out by the great mathematician Fourier into a complete analysis of diffusion by a series of harmonics. It gives primarily the flow of heat through a conductor of any shape, and it was applied by Lord Kelvin, after Fourier, to the cooling of the earth, and to diffusion in gases and liquids, and to many other phenomena. In fact the same differential equation represents his theory of signalling through an Atlantic cable. The working out of the consequences of any equation may be treated as a mathematical exercise; the interpretation of those consequences in any particular case belongs to the physicist. When the conditions are such that only *B* is zero, the equation represents the phenomenon of waves, or at least of such waves as travel with a definite velocity independent of wave-length, like air waves and ether waves.

When *C* is zero the equation represents the settling down of a disturbance, whether electrical or material, after the forces which originated the disturbance have ceased to act. The neutralization of the *C* term avoids reference to space-considerations and makes it an equation in time alone, like a law of cooling or of leakage, which last is so simple a case as not even to involve *A*; while if the right-hand side be changed to *C H* the equation represents all the laws of electrical oscillations as worked out by Lord Kelvin in 1853 and now applied in wireless wave meters. The *A* term then represents inertia, or the magnetic property called self-induction; the *B* term signifies resistance, especially the kind of electrical resistance involved in Ohm's law. When the conditions are such that *A* and *B* are both zero, things have become stationary, and the equation reduces to the one so extensively applied by Laplace to solve static gravitational problems. It embodies the conditions which gravitational fields must satisfy, and develops into part of the theory of astronomy.

When none of the coefficients is zero, and all three terms have to be taken into account (especially if a term involving *H* is added in some cases), the equation represents waves or diffusions travelling through a more complicated medium, at speeds varying with or at least dependent on the wave-length. Waves such as these can occur in the ether when it is interfered with or loaded by electrified particles, or when a medium is a polarizable insulator or a conductor. It can be made to represent the reflection of light by metals, as well as the transmission of waves through the Heaviside layer of ionized air, now becoming familiar to wireless amateurs. It also gives the Heaviside theory of cable signalling, which is more complete than Lord Kelvin's was, and which, applied in practice in America and elsewhere, has much improved long-distance telephony. Needless to say the equation in full form can do much more than that. It, or rather an interlacing set of such equations, represents the most general kind of wave; and the kingdom dominated by waves is now rapidly expanding.

The solution of such equations taxes the powers of all but high mathematicians and may lead to new functions of vast interest and importance. Skilled manipulation of the symbols by a pure mathematician is neither aided nor hindered by information about the particular things they may be intended to represent. The laws are just as valid and self-consistent even if the symbols represent imaginary quantities, as they sometimes do. In the interpretation of the integrated solution however there must be a return to reality.

The vast multitude of facts and phenomena which can thus be treated by a differential equation, so that previously unsuspected consequences can be deduced, is surely of high interest even to those whose education does not enable them to follow the details. The reason why they are so powerful in enabling latent facts to be brought to light is plain enough. It is because the actual proc-

esses at work are compactly, precisely and completely formulated, in all their interactions, by these equations, so that they embody the essence of the phenomenon; their solution and consequences can subsequently be worked out by the few who possess sufficient skill and insight. This method of procedure—from formulation, through solution, to interpretation—is indeed the highest example of the advantage possessed, and the power gained, by those who have successfully attained the aim of all science, *"rerum cognoscere causas."*

MODERN PHYSICS

So long as we are dealing with massive bodies or with great groups of particles, the laws of dynamics, based upon Newton's laws of motion and applied without any breach of continuity, were sufficient and reigned supreme. This kind of dynamics dominated the 19th century, but just at the end, as a fitting prelude to the 20th century, a number of discontinuities began to be discovered. The first discontinuity was indeed old, viz., the atomic theory of matter, and was only evaded by the fact that we inevitably dealt with great numbers of atoms. In the years 1897 to 1900 however Sir J. J. Thomson, elaborating some 1879 experiments of Sir William Crookes in a partial vacuum, discovered and finally clinched the discontinuity of electricity; in other words he realized the electron, which had previously been only surmised rather vaguely by a few. Zeeman and Lorentz had just showed that electric charges were the agents really responsible for the generation of radiation, a fact further illustrated and enforced by Röntgen's discovery of X-rays. After their isolation electrons were weighed and measured by Thomson, and found to possess the fundamental properties of matter. The nature of radiation as emitted by electrons was analysed and examined in precise detail by the spectroscope. Then another discontinuity was discovered by Max Planck, for, as soon as single atoms and their constituent particles were attended to, a new discontinuity appeared, apparently in radiation, but rather in what turned out to be a quantity connected with the orbital revolutions of an electron, akin to the sweeping out of equal areas which Kepler long ago had formulated for the planets; and Bohr formulated his astronomical theory of the structure of the atom. So through various channels it was found that these fundamental electric units, which were presumably structures in the ether, lay at the root of matter itself, and that matter was actually an electrical phenomenon. Discontinuities are natural and inevitable when dealing with individual minute particles; they were only masked in previous days because this minute treatment had not been attempted, though a hint had been given in that direction by the failure of the kinetic theory of gases, as ordinarily applied, to explain the irregular movements of very small bodies exposed to molecular bombardment.

The Theory of Relativity.—Then came the theory of relativity, which adopted, generalized, and boldly formulated a number of vague but growing suspicions. In particular it postulated a universal and unalterable constitutional velocity in the ether, now known as c, which had been recognized in Clerk Maxwell's theory as of an electromagnetic nature, but the nature of which is still unknown. This, like Planck's constant h, is found to enter into every department of physics, not only conspicuously when minute bodies are dealt with, but secretively throughout. All matter is moving through the ether, so that the constitutional velocity c of that medium enters into and modifies even the Newtonian laws of motion, thus giving a complexity which sometimes seems strange to ordinary or evolutionary experience, and with a little ingenuity can be made to appear paradoxical. Many other results of high interest follow, and the gravitational function of the medium shows signs of yielding to mathematical treatment.

The revolutionary outcome of all this is that the ether in its various forms of energy dominates modern physics, though many prefer to avoid the term "ether" because of its 19th century associations, and use the term "space." The term used does not much matter. Faraday began the discovery that it is in space that the real phenomena occur. Every differential equation is an expression in space with its three dimensions and the other abstraction called time; and some attempt has been made to unify these two great abstractions by aid of the velocity c. This however is rather verging on metaphysics, unless it is merely regarded as a legitimate convenience in calculation to deal with four similar variables instead of three and an odd one.

One definite outcome of the bold generalisations or challenges of relativity is that energy, which since its conservation was established has always been recognised as protean in form, now includes not electric charges alone but matter itself as one of its forms, so that atoms of matter might be turned into other forms of energy, if only we knew how. The idea already has some cosmological significance, for it is believed by Jeans to be the cause or mechanism of the radiation of the sun and other stars. The atom of matter is electrically constituted; it is composed of equal amounts of positive and negative electricity in its normal condition. High temperature signifies great activity or immense speeds among the atoms. They can be dissociated or broken up by collision, and their opposite ingredients may occasionally clash, lose their identity, or at least their locality, and pass quickly away as a quantum of radiation. The interior of stars is known to be at an exceedingly high temperature, and accordingly their mass is believed to be gradually decreasing, their matter dying and passing away as radiation into the depths of space. Whether there is ever or anywhere a recuperative action is at present unknown. When, if ever, such action is discovered—as is not unlikely—it will have a cosmological and philosophical bearing

It is interesting, as illustrating Newton's exceptional foresight and speculative skill, that at the end of a disquisition on the changes and interchanges of known forms of energy (though the term "energy" as a dominating physical term was not adopted till long afterwards), he should conclude thus: "And among such various and strange transmutations, why may not Nature change bodies into light, and light into bodies?"

Interaction of Matter and Radiation.—Meanwhile strange reactions have been discovered between matter and radiation Radiation is generated by electrons, and accordingly itself suffers discontinuity. Maxwell calculated that it must exert pressure: it is now found to exert pressure after the same bombarding fashion as the molecules of a gas exert it Radiation is generated and absorbed not continuously but in quanta, and these quanta exert a bombarding action as if they were particles or corpuscles; yet they must be waves, because they exhibit interference and diffraction phenomena—a study of which, in optics, began with Newton himself. Wave quanta with extra high frequency of vibration are more efficient projectiles, and eject such suitable electrons as they encounter with more energy than do those with a more ordinary rate of vibration This connection between energy and frequency is a development of Planck's quantum, which, like much else, is due to Einstein's bold and forcible conceptions The outcome of all this is that the old barrier between the corpuscular theory and the wave theory is being removed There is truth in both. High speed particles are accompanied by waves, somewhat akin to the waves at the bows of a steamer, and the apparently sharp distinction between a wave and a corpuscle is subject to a compromise which includes both.

We have long studied matter by means or by the aid of radiation or waves; we are now beginning to see that momentum, which seemed a property of matter, is possessed by waves, and that the familiar thing which we call matter is after all a manifestation or localization of ether-energy, in a form not as yet completely known or understood Ether energy—the one fundamental existence—seems to manifest itself alternatively, or even as it would seem indiscriminately, sometimes as what we might call a particle and sometimes as a wave. De Broglie seems to have initiated this idea, which has been taken up and elaborated by Schrödinger and others The result is that, whereas we once thought that we knew a great deal about an electron, its size and its speed, we are now confronted with some uncertainty. It is all very well to speculate and theorize, but all theories must be verified and brought to the test of experiment; and experiment—even indirect observation—on this minute scale is barely possible.

The difficulty can easily be rendered intelligible. We have to use some physical means to examine the behaviour of anything. We

cannot see a thing unless it is illuminated, or unless it emits light itself; and, if we are examining something very minute, the illumination itself, which consists of quanta with a definite momentum, may be altering the conditions of the very thing we want to observe. How then can we determine the position and speed of an electron? Heisenberg has shown that we cannot do both. If one determination is accurate, the other is vague. We are not even sure now of the size of an electron, for if it carries waves with it, those waves must occupy a certain region, which, though perhaps small compared with an atom, is far greater than anything we can call the electric nucleus. Indeed a highly accelerated electron, like one of those in Bohr's inner atomic orbits, seems to spread like a sinuous disturbance over the whole orbit, so that only in the outer and larger orbits is there any close correspondence between ordinary dynamics and actual fact. That there is a correspondence at all is satisfactory, but there is much detail in the ultimate minutiae which at present escapes us.

The difficulty of examining very small things by reason of the perturbations introduced by our measuring instruments can be illustrated in a simple manner. To take the temperature of a hot bath is easy enough, but a thimbleful would be chilled or otherwise altered by the thermometer employed. It is in fact difficult to observe any very small quantity without introducing perturbations. Heisenberg has actually formulated a law of uncertainty, in a singularly definite manner, showing that Planck's quantum is involved. There is an uncertainty in the position of an electron, and an uncertainty about its speed or momentum. The product of the two uncertainties is, strange to say, equal to Planck's constant h.

There are still more recent developments. Speculation is active, the revolution is in progress and fresh discoveries are constantly being made. The whole constitutes an elaborate network of interlockings and coincidences, which must have a deep-seated meaning when we can unravel the tangled skein. All we can do now is to hint at the stages that are being reached, to realize that nothing like the last word has been spoken, to wonder at the genius which has so greatly illuminated and yet partly confused us and to have faith in the advent of a great generalization. (O. J. L.)

PHYSICS, ARTICLES ON. The Physics programme is one of the most comprehensive and authoritative of the different divisions of the *Encyclopædia*. From the nature of the science close interrelation between the different branches of theory and research is possible and the various authors have combined to produce an interactive whole. In drafting the original programme it was found advisable to survey the field of physics by sub-divisions or departments, such as Heat, Light, Sound, Electricity and Magnetism (this having also a special section, Wireless Division), Electricity, Magnetism, Atomics and Radiation, and General.

Among the general articles those most important for the purpose of introducing the reader to the more specialised discussions are those dealing with SCIENCE; BAROMETER; DENSITY; ENERGY, CONSERVATION OF; GRAVITATION; HYDROMETER; DYNAMO-ELECTRIC MACHINE; DYNAMOMETER; KINETIC THEORY; PERPETUAL MOTION (which deals with the numerous attempts to construct a machine which, without outside power, will forever keep moving in a normal manner), exposing the fallacies which have underlain all such efforts; UNITS, DIMENSIONS OF; PHYSICAL UNITS; PHYSICAL CHEMISTRY; MEASUREMENTS; METROLOGY; RELATIVITY; SPACE AND TIME, and SOLID STATE, THEORY OF.

The general article *Science*, starting with a definition, proceeds to survey the whole world of scientific achievement. The first sub-section deals with the origin of science, beginning "in the slow and unconscious observation by primitive races of men of natural occurrences, such as the apparent movements of the heavenly bodies and in the gradually acquired mastery over the rude implements by the aid of which such men strove to increase the security and comfort of their lives." The origin of modern science in the explanation of the phenomena of nature by anthropomorphic or mythological interpretation is the beginning from which one is led gradually to a study of early astronomy.

From early astronomy we proceed to a discussion of the problem of matter and the theory of Atoms. The theories of the old Ionian nature philosophers are stated and their division of the elements examined. From this point we proceed gradually to a study of early biology; the belief of primitive man that disease was due to the action of some malignant demon or to the spells of some human enemy, developed into a more rational understanding of the real origin of life and disease. From the half-understood spell-binding stage of magic and witchcraft, man came to feel that his body and its growth was part of the general principle of development and was not subject to magical formulas and tabus.

Then comes a discussion of Geometry, born of the desire of man to know the measure of the world in which he lived. It was not long before man realized another aspect of scientific activity which resulted in the origin of mechanics. This is followed by an historical account of the dark ages and the mediaeval period, "the ancient knowledge only survived fragmentarily in compendiums written just before the dark ages." The Renaissance follows and we are then brought to the true method in physics with Galileo Galilei (1564–1642) and the foundation of the science of dynamics. In the 19th century came the application of similar principles in the study of geology. The development of physiology and biology from the 17th century onwards is traced, and the remainder of the article concerns itself with modern physics, finishing with sections on the methods and meaning of science, the classification of the sciences, and the philosophical basis of science.

In addition to the main article PHYSICS, where the history and development of the science are discussed, all main subdivisions of the subject have separate headings. PHYSICAL OPTICS includes a discussion of Polarization, Absorption, Dispersion, Reflexion and Refraction. Other important articles connected with LIGHT are OPTICS; BINOCULAR INSTRUMENT; DIFFRACTION; INTERFEROMETER; MICROSCOPE; MIRROR; LENSES; PHOTOGRAPHY; PHOTOMETRY; SKY; PERISCOPE; LIGHT and VELOCITY.

Sound is treated thoroughly as to general principles and allied studies such as Acoustics in the article SOUND, THEORY OF. The articles on TALKING-MACHINE include gramophone and phonograph and deal with the general mechanical reproduction of sound.

In the general article ELECTRICITY are included discussions of Electrostatics and Electrokinetics as well as a detailed history of the development of electrical theory. Further important articles in this subsection are ACCUMULATOR; ELECTRICAL INSTRUMENTS; ELECTROLYSIS; ELECTRON; ELECTROMAGNET; CONDENSER; TELEPHONE; PHOTOMETRY AND TELEVISION, and THERMOELECTRICITY. In the wireless subdivision of the electrical division there are many important articles including ATMOSPHERIC ELECTRICITY; ELECTRIC WAVES; TELEGRAPHY; BROADCASTING and RADIO RECEIVER.

MAGNETISM is an historical study of the development of magnetic theory up to modern times. There are many important subdivisions and small definition articles such as COMPASS; DIAMAGNETISM; FERRO-MAGNETISM, and HYSTERESIS refer the reader to the proper subdivision of the main article where further information is to be found. The article MAGNETO HIGH TENSION, besides surveying the general field includes studies of Inclinometer, Magnetograph and Magnetometer.

In the section of Atomics and Radiation the most important articles are ATOM, STRUCTURE OF; MATTER; CONDUCTIVITY, dealing with this principle in Solids, in Liquids, and in Gases; POSITIVE RAYS; QUANTUM THEORY; NUCLEUS; RADIATION, ELECTROMAGNETIC; SPECTROSCOPY; X-RAYS; PHOTOELECTRICITY, etc. The various movements and effects are treated under their own headings as in PHOTOELECTRICITY; ZEEMAN EFFECT; STARK EFFECT and COMPTON EFFECT and what may be called the key article is a lengthy exposition of RADIOACTIVITY. Special attention has been paid to the bibliographies of the physics articles and a comprehensive system of cross-references is designed to give the reader a complete survey of the subject.

PHYSICS IN MEDICINE. The science of physics concerns itself with energy in its various manifestations and the properties of matter, and in consequence plays a part in medicine whose value and importance are ever increasing. It furnishes means of investigating the structure of the animal body and the functions of its members; it assists in the detection of abnormality

and disease, and in the preparation, control and administration of therapeutic remedies; finally, it enables man to acquire a measure of control of his environment by scientific heating, lighting, ventilation and drainage, and the development of means of transport for himself and his necessities.

In particular, such processes of the living body as muscular contraction, the circulation of the blood, the respiratory intake and output of the lungs, the nervous impulse and its journeyings and the maintenance of the energy balance by food intake are in a measure explicable in terms of physics and physical chemistry.

Source of Bodily Energy.—To consider some of these in detail, first the question of the energy value of food may be cited. According to the principle of conservation of energy—if this is valid for transformations of energy occurring in the living animal—the same amount of energy should be evolved from the utilisation of food inside the body as outside, provided the resulting chemical end-products are the same in the two cases and have the same physical state. This has been shown to be the case by the direct measurement over a sufficiently long period, of the heat given out by resting man or animal when placed in a suitable calorimeter, and by also separately measuring the heat evolved in the oxidation of a quantity of food equal to that which was consumed in this period. When due allowance is made for substances which are excreted unchanged or only partially oxidized, and for the work of evaporation, it is found that the agreement is beyond doubt. This is of considerable importance, for if it were not the case, then it would be quite uncertain whether or not man received energy from unknown sources and physics would be of little use in medicine. As it is, the fact that the oxidation of food is the only source of bodily energy of man, makes possible the prescription of diets adequate to a variety of conditions, whether of health or disease.

Not only does the principle of conservation of energy apply to the body as a whole, it is also applicable to the units which go to form it, *i.e.* to all those energy changes and oxidations necessary for life which occur in the cell. Now the living cell consists of a watery solution containing colloids, crystalloids and substances in suspension, enclosed in a cell wall or membrane. Therefore the study of the physical properties of solutions, colloids and membranes in the laboratory should, and does, afford much information concerning its behaviour. Below some of these properties are examined with this object.

Hydrogen Ion Concentration.—It is well known that solutions which conduct electricity (electrolytes) do so in virtue of the electrically charged "ions," positive and negative, derived from the dissociation of the molecules of the dissolved substances. Pure water is only slightly ionized, yielding hydrogen ions carrying a positive electrical charge and an equal number of hydroxyl ions with a negative charge, the product of the concentration of hydrogen ions and hydroxyl ions being constant for a given temperature. When a substance is dissolved in water it, in general, produces a change in its chemical neutrality, owing to the disturbance in the balance existing between the concentration of hydrogen and hydroxyl ions. Thus an acid dissolved in water yields hydrogen ions as a direct result of solution, and leads to an increase in hydrogen ion concentration and a decrease in the concentration of hydroxyl ions. Similarly the solution of a base produces hydroxyl ions and leads to a decrease in hydrogen ion concentration and an increase in the concentration of hydroxyl ions.

Acidity then is due to the preponderance of hydrogen ions over hydroxyl ions, and alkalinity is due to the converse. Neutrality is an equilibrium of hydrogen and hydroxyl ions. Certain substances—called amphoteric electrolytes—produce both hydrogen ions and hydroxyl ions on dissociation, and may therefore combine as acids with bases, or as bases with acids. Proteins are of this class, and so of course, is water.

An alteration in acidity is the causative factor in the regulation of respiration, the activity of muscle, and the excitability of nerve and plays an important part in regulating excretion and secretion.

The powerful effects of variation in hydrogen ion concentration on physiological processes require the existence of mechanism for the prevention of considerable changes of this kind. One of the main functions of blood is to provide this. It can itself withstand the addition of relatively considerable amounts of free acid or free alkali without much change in its reaction, largely owing to the presence of carbonates and phosphates. The electrolytic dissociation theory provides the only satisfactory explanation of this.

Colloids and Membranes.—The colloidal state is recognised as a permanent suspension of solid particles or liquid globules in a continuous medium of a different kind. In contrast to true solutions, colloids are heterogeneous systems in which the suspended particles are large enough to possess the special properties peculiar to surfaces. It is easily seen that, since molecules at the surface of separation of two phases are attracted more powerfully in the direction of the phase to which they belong than in the opposite direction, the interface will be in a state of tension. Consequently any change in the area of a surface film will result in a loss or gain of surface energy. Again, particles of colloid solutions usually possess an electrical charge, which is localized on its surface. Such particles are to a large extent prevented from aggregating together and falling as precipitates by the mutual repulsion of their electrical charges.

The deposition of charged ions on a colloidal particle or any surface would confer on the surface a charge of corresponding sign. This process is called *adsorption* and it may or may not be accompanied by chemical action between the constituents of the surface and the adsorbed material. The neutralization of electrical charges by adsorption of oppositely charged ions from added neutral salts results in precipitation. A similar effect may be produced by oppositely charged colloids.

An important case of adsorption is that occurring at the semipermeable membrane which covers cells. Physical principles show that any material which lowers surface energy will be accumulated in the surface. Certain substances, such as proteins, may form solid deposits in the surface films owing to their concentration brought about in this way. These deposits are capable in some cases of being redissolved if carried into the interior of the cell. Hence the cell membrane must have a variable structure in equilibrium with its contents.

Osmotic Pressure.—Semi-permeable membranes, *i.e.*, membranes which allow water to pass freely, but hold back dissolved substances exhibit another important property. Water will tend to diffuse more rapidly through the membrane towards that side on which the concentration of dissolved substance is greater, than in the reverse direction. This would cause a difference in hydrostatic pressure on the two sides if an increase in volume of the more concentrated solution is prevented by a non-yielding envelope. This pressure is called *osmotic pressure* and the unilateral passage of fluid *osmosis* (*q.v.*). Solutions which exert the same osmotic pressure are said to be *isotonic*.

It is easy to see that the solutions which bathe a cell not enclosed in a rigid envelope must, for equilibrium, possess the same osmotic pressure as the cell contents. Otherwise the cell will contract through loss or expand through gain of water, and will be destroyed unless the osmotic pressures can be equalized in this way. In any case if any change of concentration occurs, the functional activity of the cell will be affected. The membrane covering individual cells and blood corpuscles is impermeable to salts, glucose, etc.; that forming the walls of the capillary blood vessels is permeable to these but not to colloids.

The osmotic pressure of colloids although it is very small compared with that of solutions of electrolytes, has been shown by Starling to play an important part in the formation of urine. Oedema also, according to some authors, is a phenomenon of osmosis.

The chemical behaviour of colloidal particles is very inert compared with the same amount of material in true solution. This permits of the use in medicine of colloidal preparations of metals and other powerful drugs to secure a slow and prolonged action of continuous minute doses of the active ionized form into which they break down.

The reference already made to the properties of colloids and electrolytes and to some of the parts they play in the animal body, are properties and phenomena which demanded for their elucidation the use of the microscope, ultra-microscope, polarimeter, electrometer, etc.

Physics of Muscle and Nerve.—The study of the action of muscles and nerves illustrates perhaps in a still more definite manner, the dependence of medical on physical science. This dependence is twofold, in that the investigation and rational explanation of physiological phenomena has had to await, not only the development of physical theory for the realm of inanimate matter, but also the invention and technical perfection of detecting and recording instruments of the greatest sensitivity and highest precision.

In order to maintain living muscles and nerves outside the animal for long periods they are bathed in an artificial saline solution, which, as we have seen, must be isotonic with them and have the same hydrogen ion concentration Now much of the difficulty in investigating vital processes is due to the microscopic size of the living cell, which results in changes which are also small Largely owing to the development of sensitive galvanometers and also to the modern thermionic amplifier and cinematograph camera, it is possible to detect extremely small variations of energy if they occur in the form of electrical changes or can be converted into that form. Minute changes of temperature—and therefore the production of small quantities of heat—can be measured by the electrical currents generated in thermocouples or by changes in electrical resistance of metallic conductors.

Methods of Investigation.—In studying the activity of an isolated nerve or muscle preparation, it is usual to employ a brief electric current as stimulus, since it is possible to repeat it without producing permanent damage and the duration and intensity can be so readily and accurately controlled By these means, it has been possible to measure with some accuracy the heat produced in a muscle by a single stimulus, and also that liberated over long intervals at rest, or in recovery after prolonged stimulation. The results prove that oxidation is necessary to maintain the normal life and structure of an animal cell in a living but completely resting condition. Further it has been shown that muscular contraction is a surface phenomenon, since the energy developed is proportional to the *length* of the fibres and not their volume.

Similarly it has been shown that the nervous impulse is excited by a stimulus which in all probability consists in an accumulation of ions in certain parts of the nerve fibre. The arrival of the impulse at any point on the nerve is indicated by the active region developing a negative electrical potential with regard to the neighbouring inactive regions. If then, electrodes are placed in contact with the active and inactive regions and connected through a galvanometer, a current will pass through the circuit towards the active region. It is found that the energy involved in the transmission of the impulse is derived from that stored in the fibre itself, and not from the stimulus: the latter only acts as a trigger.

Radiation.—Not the least service rendered by physics to medicine is the demonstration and exploitation of the fact that, in addition to those radiations—light and radiant heat—which are directly perceived through the senses, there exist others which have a profound influence on the animal body. The spectrum of electromagnetic radiation is now known to comprise, in descending order of wave lengths, the Hertzian waves of wireless communication, infra-red rays, the visible spectrum, ultra-violet rays, X-rays and the gamma rays of radio-active substances The shorter wave lengths of the visible spectrum and the still shorter ones mentioned above, all possess the power of either stimulating or destroying the animal cell, according as the quantity of energy absorbed is small or excessive. The action of the rays is *selective* in that different cells exhibit different degrees of response to a given quality and intensity of radiation.

Some radiations, notably those from certain parts of the ultra-violet spectrum, have a *specific* action on biological material, *i.e.*, the absorption of a given amount of radiant energy of this wave length will provoke a much greater response in a given cell or organism than the absorption of an equal amount of energy of another wave length.

These two effects—the specific and the selective effects of different radiations—are of great importance in radiation therapy

The mechanism of the action of radiation on the cell has not been traced in all its stages Ultimately, however, it is attributable either to the heat produced by the energy absorbed, or to the ionizing (photo-electric) effect on the atoms of the cells involved. The principal methods of physical dosage measurement in radiation therapy also depend on these two last mentioned properties. Exact dosage measurements have shown that the biological reactions produced by different kinds of radiation obey similar laws in that they all require a minimum duration and have a threshold value of intensity below which no effect is produced.

For other applications of physics to medicine the reader should consult the following articles —PHYSIOLOGY; HYGIENE; ELECTRO-THERAPY; X-RAYS, RADIUM. (F. HD)

PHYSIOCRATIC SCHOOL, the name of a group of French economists and philosophers. The heads of the school were François Quesnay (*q.v.*) and Jean Claude Marie Vincent, sieur de Gournay (1712–1759). The principles of the school had been put forward in 1755 by R Cantillon, a French merchant of Irish extraction (*Essai sur la nature du commerce en général*), but it was Quesnay and Gournay who gave them a systematic form, and made them the creed of a united group of thinkers and practical men, bent on carrying them into action. The members of the group called themselves *les économistes*, but it is more convenient, because unambiguous, to designate them by the name *physiocrates* (Gr. φύσις nature, and κρατεῖν to rule), invented by P. S. Dupont de Nemours (1739–1817)

The general political doctrine is as follows: Society is composed of a number of individuals, all having the same natural rights If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own interest, and is led by nature to follow it The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each just so far as it is inconsistent with the rights of the others. Government though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere this implies the right of the individual to such natural enjoyments as he can acquire by his labour That labour, therefore, should be undisturbed and unfettered, and its fruits should be guaranteed to the possessor; in other words, property should be sacred. Each citizen must be allowed to make the most of his labour; and therefore freedom of exchange should be ensured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The Single Tax on Land.—The physiocrats then proceed with the economic analysis thus: Only those labours are truly "productive" which add to the quantity of raw materials available for the purposes of man, and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course, metals) over their cost of production On the amount of this *produit net* depends the well-being of the community and the possibility of its advance in civilization The manufacturer merely gives a new form to the materials extracted from the earth; the higher value of the object, after it has passed through his hands, only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another; what the trading classes gain thereby is acquired at the cost of the nation, and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are "useful" indeed, but they are "sterile," drawing their income, not

from any fund which they themselves create, but from the superfluous earnings of the agriculturist. The revenue of the state, which must be derived altogether from this net product, ought to be raised in the most direct and simplest way—namely, by a single impost of the nature of a land tax.

The special doctrine relating to the exclusive productiveness of agriculture arose out of a confusion between "value" on the one hand and "matter and energy" on the other. A. Smith and others have shown that the attempt to fix the character of "sterility" on manufactures and commerce was founded in error. And the proposal of a single *impôt territorial* falls to the ground with the doctrine on which it was based. But such influence as the school exerted depended little, if at all, on these peculiar tenets, which indeed some of its members did not hold. The effective result of its teaching was mainly destructive. It continued in a more systematic form the efforts in favour of the freedom of industry already begun in England and France.

The Rule of Nature.—These conclusions as to the revolutionary tendencies of the school are not at all affected by the fact that the form of government preferred by Quesnay and some of his chief followers was what they called a legal despotism, which should embrace within itself both the legislative and the executive function. The reason for this preference was that an enlightened central power could more promptly and efficaciously introduce the policy they advocated than an assembly representing divergent opinions and fettered by constitutional checks and limitations. Turgot used the absolute power of the Crown to carry into effect some of his measures for the liberation of industry, though he ultimately failed because unsustained by the requisite force of character in Louis XVI. But what the physiocratic idea with respect to the normal method of government was appears from Quesnay's advice to the dauphin, that when he became king he should "do nothing, but let the laws rule," the laws having been, of course, first brought into conformity with the *ius naturae*. The partiality of the school for agriculture was in harmony with the sentiment in favour of "nature" and primitive simplicity which then showed itself in so many forms in France, especially in combination with the revolutionary spirit, and of which Rousseau was the most eloquent exponent. The members of the physiocratic group were undoubtedly men of thorough uprightness, and inspired with a sincere desire for the public good, especially for the material and moral elevation of the working classes. Quesnay was physician to Louis XV., and resided in the palace at Versailles; but in the midst of that corrupt court he maintained his integrity, and spoke with manly frankness what he believed to be the truth. And never did any statesman devote himself with greater singleness of purpose or more earnest endeavour to the service of his country than Turgot, who was the principal practical representative of the school.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds. Its members, writing on dry subjects in an austere and often heavy style, did not find acceptance with a public which demanded before all things charm of manner in those who addressed it. The physiocratic tenets, which were in fact partly erroneous, were regarded by many as chimerical, and were ridiculed in the contemporary literature; as, for example, the *impôt unique* by Voltaire in his *L'Homme aux quarante écus,* which was directed in particular against P. P. Mercier-Larivière (1720–1794). It was justly objected to the group that they were too absolute in their view of things; they supposed, as Smith remarks in speaking of Quesnay, that the body politic could thrive only under one precise régime—that, namely, which they recommended—and thought their doctrines universally and immediately applicable in practice. They did not, as theorists, sufficiently take into account national diversities or different stages in social development; nor did they, as politicians, adequately estimate the impediments which ignorance, prejudice and interested opposition present to enlightened statesmanship.

The physiocratic system, after guiding in some degree the policy of the Constituent assembly, soon ceased to exist as a living power; but its good elements were incorporated into the more complete construction of Adam Smith.

See the articles on Quesnay (with bibliography), Mirabeau and Turgot; also Tocqueville, *L'Ancien régime et la révolution,* ch. iii.; Taine, *Les Origines de la France contemporaine,* vol. i.; R. Stourm, *Les Finances de l'ancien régime et de la révolution* (1885); J. F. X. Droz, *Histoire du règne de Louis XVI.*; L. de Lavergne, *Économistes français du XVIII.e siècle* (1876); H. PHYSIOGNOMY, a term which denotes a supposed science for the "discovery of the disposition of the mind by the lineaments of the body" (Bacon); is also used colloquially as a synonym for the face or outward appearance, being variously spelled by the old writers.

Physiognomy was regarded by those who cultivated it as a two-fold science: (1) a mode of discriminating character by the outward appearance, and (2) a method of divination from form and feature. On account of the abuses of the latter aspect of the subject its practice was forbidden by the English law. By the act of parliament 17 George II. c. 5 (1743) all persons pretending to have skill in physiognomy were deemed rogues and vagabonds, and were liable to be publicly whipped, or sent to the house of correction until next sessions. The pursuit thus stigmatized as unlawful is one of great antiquity: in ancient times physiognomy was a profession.

The first systematic treatise which has come down to us is that attributed to Aristotle, in which he devotes six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness, of genius and stupidity, of timidity, impudence, anger and their opposites, etc. Then he studies the physiognomy of the sexes, and the characters derived from the different features, and from colour, hair, body, limbs, gait and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard. The general character of the work may be gathered from the following specimen. While discussing noses, he says that those with thick bulbous ends belong to persons who are insensitive, swinish; sharp-tipped belong to the irascible, those easily provoked, like dogs; rounded, large, obtuse noses to the magnanimous, the lion-like; slender hooked noses to the eagle-like, the noble but grasping; round-tipped retroussé noses to the luxurious, like barndoor fowl; noses with a very slight notch at the root belong to the impudent, the crow-like; while snub noses belong to persons of luxurious habits, whom he compares to deer; open nostrils are signs of passion, etc.

While the earlier classical physiognomy was chiefly descriptive, the later mediaeval authors particularly developed the predictive and astrological side, their treatises often digressing into chiromancy, onychomancy, clidomancy, podoscopy, spasmatomancy and other branches of prophetic folk-lore and magic.

Along with the medical science of the period the Arabians contributed to the literature of physiognomy; notably 'Ali b. Ragel, Rhazes and Averroes. Avicenna also makes some acute physiognomical remarks in his *De animalibus,* which was translated by Michael Scot about 1270. Among mediaeval writers Albertus Magnus (born 1205) devotes much of the second section of his *De animalibus* to physiognomy. The famous sage of Balwearie, Michael Scot, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis phisiognomia,* much of which is physiological and of curious interest. It was probably composed about 1272, but not printed until 1477. This was the first printed work on the subject.

The 16th century was rich in publications on physiognomy. Treatises were published, among others, by John de Indagine, Cocles, Andreas Corvus, Michael Blondus, Janus Cornaro, Anselm Douxciel, Pompeius Ronnseus, Gratarolus, Lucas Gauricus, Tricassus, Cardanus, Taisnierus, Magnus Hund, Rothman, Johannes Padovanus, and, greatest of all, Giambattista della Porta. The earliest English works were anonymous: *On the Art of Foretelling Future Events by Inspection of the Hand* (1504), and *A Pleasant*

Introduction to the Art of Chiromancie and Physiognomie (1588). Dr. Thomas Hill's work, *The Contemplation of Mankynde, contayning a singular Discourse after the Art of Physiognomie*, published in 1571, is a quaintly written adaptation from the Italian authors of the day.

The development of a more accurate anatomy in the 17th century seems to have diminished the interest in physiognomy by substituting fact for fiction; and consequently the literature, though as great in quantity, became less valuable in quality. The principal writers of this age were T. Campanella, R. Coclenius, Clement, Timpler, J. E. Gallimard, Moldenarius, Septalius, Saunders, C. Lebrun (a precursor of Charles Bell), Elsholz, de la Bellière, J. Evelyn (in the appendix to *Numismata*), Baldus, Bulwer (in his *Pathomyotomia*), Fuchs, Spontoni, Ghiradelli, Chiaramonti, A. Ingegneri, Finella, De la Chambre, Zanardus, R. Fludd and others of less importance.

The 18th century shows a still greater decline of interest; the only name worthy of note is that of J. K. Lavater (*q.v.*) The popular style, good illustrations and pious spirit of his works gave them a popularity they little deserved, as there is no system in his work, which chiefly consists of rhapsodical comments upon the several portraits.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, whose *Essay on the Anatomy of the Expression*, published in 1806, was the first scientific study of the physical manifestation of emotions in the terms of the muscles which produce these manifestations. In the later editions of this essay the thesis is elaborated with greater detail. Moreau's edition of Lavater, in 1807, was somewhat along the same lines. In 1817 Dr. Cross of Glasgow wrote his defence of a scientific physiognomy based on general physiological principles. The experiments of G. B. A. Duchenne (*Mécanisme de la physiognomie humaine, Paris*, 1862) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These observations confirmed by experimental demonstration the hypothetical conclusions of Bell. The machinery of expression having thus been indicated, the connection of the physical actions and the psychical state was made the subject of speculation by Herbert Spencer (*Psychology*, 1855). These speculations were reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated the following as fundamental physiognomical principles:—

(1) Certain complex acts are of direct or indirect service, under certain conditions of the mind, in order to relieve or gratify certain sensations or desires; and whenever the same states of mind are induced the same sets of actions tend to be performed, even when they have ceased to be of use. (2) When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action. (3) When the sensorium is strongly excited nerve-force is generated in excess, and is transmitted in definite directions, depending on the connections of nerve-cells and on habit.

The last of these propositions is adversely criticized by P. Mantegazza as a truism, but it may be allowed to stand with the qualification that we are ignorant concerning the nature of the influence called "nerve-force" It follows from these propositions that the expression of emotion is, for the most part, not under control of the will, and that those striped muscles are the most expressive which are the least voluntary. To the foregoing may be added the following three additional propositions, so as to form a more complete expression of a physiognomical philosophy:—

(4) Certain muscles concerned in producing these skin-folds become strengthened by habitual action, and when the skin diminishes in elasticity and fulness with advancing age, the wrinkles at right angles to the course of the muscular fibres become permanent. (5) To some extent habitual muscular action of this kind may, by affecting local nutrition, alter the contour of such bones and cartilages as are related to the muscles of expression. (6) If the mental disposition and proneness to action are inherited by children from their parents, it may be that the facility in, and disposition towards, certain forms of expression are in like manner matters of heredity.

Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne and Darwin, and in the later publications of Theodor Piderit, *Mimike und Physiognomik* (1886) and Mantegazza, *Physiognomy and Expression* (1890), to which the student may be referred for further information.

For information on artistic anatomy as applied to physiognomy *see* the catalogue of sixty-two authors by Ludwig Choulant, *Geschichte und Bibliographie der anatomischen Abbildung*, etc. (Leipzig, 1852), and the works of the authors enumerated above, especially those of Aristotle, Franz, Porta, Cardan, Corvus and Bulwer. For physiognomy of disease, besides the usual medical handbooks, *see* Cabuchet, *Essai sur l'expression de la face dans les maladies* (Paris, 1801); Mantegazza, *Physiology of Pain* (1893), and Polli, *Saggio di fisiognomonia e potognomonia* (1837). For ethnological physiognomy, *see* amongst older authors Gratarolus, and amongst moderns the writers cited in the various textbooks on anthropology, especially Schadow, *Physionomies nationales* (1835) and Park Harrison, *Journ. Anthrop. Inst.* (1883). For the physical characteristics of criminals *see* Lombroso, *L'Uomo delinquente* (1897); Ferri, *L'Omicidio* (1895); von Baer, *Der Verbrecher* (1893); Laurent, *Les Habitués des prisons* (1890); Havelock Ellis, *The Criminal* (1901); A. Lenz, *Grundriss der Kriminalbiologie* (Vienna, 1927); L. Grinberg, *Emotion and Delinquency* (1928).

PHYSIOLOGICAL ARTICLES. The special articles in Physiology form natural complements to those of the medical programme. DIGESTION; HEART AND CIRCULATION; NUTRITION; EQUILIBRIUM; MUSCLE AND MUSCULAR EXERCISE; PAIN, SIGNIFICANCE OF; BIOCHEMISTRY; TASTE AND SMELL; ENZYMES and REPRODUCTION and SEX, are among the most important articles in this section. *See* also MEDICAL ARTICLES.

PHYSIOLOGY is the science which treats of the functional working of the body in health, as opposed on the one hand to anatomy which treats of the structure of the body and pathology which treats of its function as distorted by disease. In all forms of animal life except the lowest, the body is made up of organs. With regard to the functions of all the more important organs special articles will be found under their respective names (*see* HEART; INTESTINE, LIVER; LUNG; etc).

The activities of these organs are co-ordinated by the nervous system (*see* BRAIN; NERVE; SPINAL CORD; SYMPATHETIC SYSTEM) and the hormones (*see* HORMONES) Nevertheless the body is in a sense more than a number of co-ordinated units. The body has an architecture which has been evolved along well defined lines and which it is the business of the present article to trace as far as may be possible.

The phrase "well defined lines" rather than "well defined principles" has been used advisedly; for it may often be a matter of speculation, whether, even when a frequent repetition of the same sort of architectural conceit occurs, any principle is really involved; or whether merely the same sort of accident has taken place in the same sort of way. To the most reflective type of mind physiology presents no more fascinating problem, than that of the extent to which the structure of the body is the result of some well ordered plan either of "evolution" or "design." In the strict sense of the word "principle" would imply such a plan, but in what follows the word will be used more loosely to include phenomena that recur with sufficient frequency to simulate an orderly sequence, even though the recurrence may in reality be little more than accidental.

Constancy of Internal Environment.—This principle is associated particularly with the name of the great French physiologist Claude Bernard. Innumerable examples might be given in illustration of it but a few must suffice Moreover the examples might be either in the realm of the physical or of the chemical properties of the environment The first to be discussed, namely constancy of internal temperature, is physical and is chosen not because it is more important than others, but because the constancy has crept into the animal kingdom very slowly and its implications are to some extent traceable A unicellular organism, such as the amoeba, exists at a temperature indistinguishable from that of the water in which it lives. Every accident which affects the temperature of the water affects that of the amoeba; the only defence which the creature can put up against a too rigorous environment, whether of heat or cold, is to flee if it can to more genial surroundings. Within those limits all the processes of its body, of digestion, of respiration, of movement, must take place at the temperature of the water in which the unicellular organism finds itself. Compare the condition of affairs in man, the most

highly organized creature; the temperature of the body is within very narrow limits (1) constant from one time to another; (2) the same over the whole body; and (3) maintained at a level quite different from—and independent of—that of the surrounding medium.

In the development of man, this constancy has been brought about by stages. The root of the matter lies in the fact that the organism itself produces heat; the amoeba is so small and its cooling surface relatively so great, that the heat produced by the organism itself is a negligible factor in determining its temperature; but if enough amoebae were packed together the heat which they produced would have less opportunity of escape and so the centre of the mass would attain a higher temperature just as the heat produced in a hay rick raises the temperature of the interior of the rick. Therefore a high body temperature argues a certain considerable *size* as one of the properties of the body. That the body temperature should be uniform over the whole body is accomplished by the circulation of the blood. The maintenance of the constancy of environment inside the body by the device of circulating the same fluid throughout all its interstices appears very early in the development of animal life and maintains the constancy in many other respects besides that of temperature.

The constancy of the body temperature with regard to time is on the other hand something which has been attained at a late stage in the development of the animal kingdom. The so called "warm blooded animal," in reality the animal whose temperature remains at an even level, did not appear until long after the vertebrate level had been reached. Yet this device was developed apparently independently both in birds and mammals.

So manifest are the advantages of a constant temperature that its late development seems almost surprising. The body from one point of view consists of innumerable and ceaseless chemical reactions. These reactions take place at given velocities, the velocity of each reaction depending upon the reaction itself and the temperature at which it is taking place. Imagine the whole machine adjusted perfectly to work at 30° Cent., each reaction progressing at a velocity which (a) is most suitable for its own purpose, and (b) fits into the general scheme so nicely that the whole multitude of reactions take place harmoniously. Now alter the temperature from 30° to 10°; some of the reactions are affected much by the alteration, some little; chaos must result and the whole machine be thrown out of gear. Therefore a third condition (c) is necessary, namely, that the effect of temperature on the velocities of the reactions must be such that when the temperature is altered the reactions alter in speed harmoniously with one another. This fresh condition naturally limits the number and nature of the chemical processes, which are available. Some chemical operation might be most desirable and could take place at 37° C, but its insertion into the body would be merely vicious if, by refusing to keep pace with its fellows, it brought the mechanism to a standstill at 10° C. By maintaining a uniform temperature condition (c) is dispensed with and the body is free to select what chemical reactions are most suitable under the constant condition without reference to the extent to which they may be affected by alteration of the temperature.

The constancy of the body temperature is maintained by a nice adjustment of the heat loss of the body to the heat formation; for the mechanism of this adjustment *see* the article on ANIMAL HEAT; here it need only be said that the adjustment is controlled entirely by the nervous system.

Alkalinity of the Blood.—The second property of the internal medium, which is maintained at an approximately constant level, is the alkalinity of the blood. Great prominence has been given to the study of the hydrogen ion concentration of the blood within the last decade. So far as is known the limits within which the alkalinity of the blood may vary are between pH 8·00 and pH 7·00. The work of L. J. Henderson and of Hasselbalch has gone to show that the hydrogen ion concentration depends not upon the actual quantity of acid or alkali present but upon the balance between the two. In a system consisting of carbonic acid and sodium bicarbonate in solution the hydrogen ion concentration,

$$cH = K \times \frac{(CO_2)}{(NaHCO_3)}$$

where K is a constant and (CO_2) and ($NaHCO_3$) the molecular concentrations respectively of carbonic acid and sodium bicarbonate, from which it follows that addition of water to the system will not alter the hydrogen ion concentration.

Every action of the body tends to upset this equilibrium usually in the sense of putting more acid into the blood; muscular exercise for instance adds carbonic and sometimes lactic acid to the circulating medium. How then is the constancy maintained? First by the action of the respiratory system. Increase of the hydrogen ion concentration of the blood leads to increased activity of the respiratory centre, and greater consequent loss of carbonic acid by the body in the breath. Secondly the kidney comes into play and if the concentration of acid in the blood falls alkali is secreted in correspondingly excessive amounts in the urine. Whether the central nervous system controls the output of alkali by the kidney is not known. The actual secreting cells of the kidney are not regarded as being operated by nerves; if therefore the nervous system plays a part it probably does so by controlling the blood supply.

Two examples have been taken for consideration but the reader can from any book on physiology learn of many more, such as the constancy of sugar, of protein, of the calcium-phosphorus ratio of oxygen, of haemoglobin and so forth. Yet these are not absolutely constant in the blood but their variation is within small limits—any considerable deflection from which is in health soon redressed.

The Principle of Maximal Activity.—The most elementary consideration of the architecture of any structure demands some discussion of the sizes of the various components. This question has received little attention from the physiological point of view. The anatomist has tabulated the average dimensions of the various organs but the physiologist has little to say about the reasons which determine these sizes. What little there is on this subject in the literature of physiology is not always to the point. The human body at rest may be compared to a battleship with her fires lit, her ammunition on board and her guns ready for action. Any description of such a ship is, however, given in terms of the energy she puts forth, not when at rest, but when in the fullest possible activity; she has a speed of so many knots, her hitting power is so and so. Only expressed in those terms the dimensions of her various parts become intelligible. So it is with the body, but the difficulties of studying it, or any of its parts, when the maximum of energy is being developed is very great. Some decision must be come to as to the units in which the energy is to be expressed. In the case of a motor car it is expressed in terms of fuel consumed—so many miles to the gallon or to the litre. In the case of man it may also be expressed in litres—litres of oxygen used in consuming the fuel. A man may use as much as four litres of oxygen per minute. This oxygen is of course used in the tissues themselves and therefore must be carried to them. To carry four litres of oxygen efficiently requires probably about 30 litres of blood, therefore 30 litres of blood must pass out of the heart per minute. That fact fixes the size of the aorta and presumably the dimensions of the heart itself. Moreover the blood has to be oxygenated and therefore the dimensions of the lungs are also fixed. Thus the limiting factor in deciding the size of any organ has nothing to do with the events taking place in the resting body but with the maximum activity with which the organ is concerned.

A striking instance is furnished by the splenic vein. Many observers have noted that the splenic vein is large out of proportion to the quantity of blood which usually passes along it. Only recently has it been appreciated that the spleen may hold at a time perhaps one-fifth of the total quantity of blood in the body and that it may contract suddenly expelling possibly $\frac{1}{4}$ of a litre of blood in a few seconds.

What is true of the body as a whole is true of the individual organs.

The following table gives the quantity of oxygen which they are capable of using in the dog or cat:—

Voluntary muscle	Nerves cut	0·003	Tone at rest	0·006
			Gentle contraction	0·020
			Active contraction	0·080
Unstriped muscle	Rest	0·004	Contracting	0·007
Heart	Slow and feeble contraction	0·007	Normal contractions	0·05
			Very active	0·08
Submaxillary gland	Nerves cut	0·03	Chorda stimulation	0·10
Pancreas	Not secreting	0·03	Secreting after injection of secretia	0·10
Intestines	Not absorbing	0·02	Absorbing peptone	0·03
Liver	Fasting animal	0·01 0·02	Fed animal	0·03 0·05
Suprarenal	Normal	0·045		

Thirty years ago physiologists were exercised with the study of the extent to which organs could be cut away without fatal results. Bradford found that the whole of one kidney and the half of the second could be removed in animals without fatal results; it was observed also that the removal of one lung did not appear to be very serious. Men marvelled at the fact that the organs were so unnecessarily large; the standard which they applied was that of rest and not the conditions under which the kidney or the lung was required to function on the greatest scale of which it is capable.

Again it is well known that but a small portion of many of the endocrine organs, if left in the body, will apparently prevent the obvious sequelae of removal of the whole. Why then should the body contain so much more of the organ than appears necessary and why in many cases will the part left grow perhaps to the original size? Presumably because there are moments when the whole organ is required. It is in relation to such that its size is regulated.

The Principle of Mobilized Units.—When an organ becomes active it may be conceived of as doing so in one of two ways (of course the two may be combined). The first is that each unit of which the organ is composed may become heightened in activity; the second is that a single unit is capable of only two states, the active and the resting and that the degree of activity of the organ depends simply on the relative number of active and of resting units which it contains.

For many years the view has been held with regard to the heart, that that organ cannot give a partial contraction; if it contracts at all it gives the full contraction of which it is capable in the condition in which it may be at the moment. This was known as the "all or none" principle. It seemed to indicate that not only did each fibre of the heart muscle contract to its full extent but that when contraction took place, all the fibres in the heart contracted. These are two separate points. For the moment the applicability of the "all or none" principle to the cell will be considered. More recently the principle has been applied both to striated muscle and to nerve. As now conceived each fibre of which a skeletal muscle is composed, contracts to its full extent if it contracts at all, but, unlike the heart, not all the fibres need necessarily contract. Thus the degree of shortening of the muscle will depend upon the number of fibres which are thrown into contraction and not upon the degree of contraction of each.

Very beautiful records have recently been obtained of the impulses which pass up sensory nerve fibres; the same principle holds good. There is a standard impulse which can pass up, that is a property of the nerve. The gradation of the sensation depends upon the number of such which pass along the nerve in a given time, and on the number of nerve fibres which are stimulated simultaneously.

With regard to the applicability of the "all or none" law to secreting cells there is nothing known.

Passing from the consideration of cells to that of organs, one finds that there is frequently a unit between the cell and the organ; the lung consists of alveoli, the same is true of the salivary gland, the kidney consists of tubules, and so forth. Till recently it was assumed that in any one organ all the units are at work all the time, the activity of each unit being graded in the same degree as that of its fellow. With regard to the kidney Richards and Wearn have shown it to be otherwise, the degree of activity of the organ being the expression of the number of tubules which are in action at any time; for the tubules appear to work in shifts. Haldane has found reasons for suspecting the same principle to operate in the case of the lung. In normal quiet breathing he regards only a portion of the lung as being involved, while when the respiration is more laboured a larger number of alveoli become ventilated. The application of the principle of mobilized units to the lung rests, however, on a less sure basis than its application to the kidney. In the latter case the glomeruli have been seen to go in and out of action, the blood flow through them being at times suspended; in the lung it is a matter of inference.

The most striking instance of the mobilization of units is that of the capillaries as observed by Krogh. In a muscle for instance the capillaries run parallel to the muscle fibres. When the muscle is at rest the majority of these capillaries are entirely closed, no blood whatever running along them. As the muscle becomes more and more active, a correspondingly greater number of capillaries open till the maximum may be many times the number at rest.

Principle of Substantial Reserves.—The principal materials (gross) which the body requires are carbohydrate, fat, protein, water and oxygen. In the case of each the body carries some sort of store beyond that placed at the immediate seat of metabolism.

Carbohydrate.—The blood contains about 7 grams of sugar; that is a little more than half an hour's supply for the whole body. The remaining carbohydrate is stored as glycogen. Of this about half is distributed throughout the tissues generally and may therefore be regarded more or less as being at the seat of its metabolism. The remaining half, amounting to 75 grams or half a day's supply, is to be found in the liver which acts as a store for the body as a whole. Thus the body has a store of about one half day's supply of carbohydrate,—250–300 grams being the figure put down in the standard dietaries for daily consumption. That is not to say that after 12 hours' abstinence there is no carbohydrate left in the body, but it means that the organism is gradually falling back on something else.

Fat is stored on a much greater scale than carbohydrate. The amount of fat stored in the body naturally differs in different individuals within very wide limits, but it has been established as the result of numerous experiments that a portion of the fat laid down in the body is directly derived from what is eaten. Thus if some oil of low melting point be taken in the food it may at once be recognised as entering into the store of fat reserved in the body.

Whilst it is quite clear that carbohydrate eaten may be stored as carbohydrate and used as such, and while it is equally clear that fat eaten may be stored as fat, the more arresting question arises—Is not much of the fat of the body essentially a store of carbohydrate? In order to establish this thesis it would be necessary to prove (1) that carbohydrate taken may be laid on as fat; and (2) that when carbohydrate is needed fat may be reconverted into carbohydrate or at all events used as carbohydrate is used. That carbohydrate taken in the food may be laid on as fat was proved by the classical experiment of Lawes and Gilbert. In this two young pigs were chosen from the same litter and while one was killed and analysed, the other was fed on "grains," a diet which is practically free from fat, consisting of protein and carbohydrate. The amount of fat put on by the growing pig was greater than could be accounted for on the assumption that it was formed from protein. Indeed since the days of Lawes and Gilbert it has become increasingly doubtful whether fat can be formed from protein on any considerable scale in the mammal.

To pass to the possible reconversion of fat into carbohydrate,—that is at the moment a subject on which the highest authorities are in controversy. It may be that when muscle is in want of carbohydrate and cannot get any from the usual sources fat is reconverted, but it may not be so. If it is not, however, there appears to be but one possibility, namely, that the muscle can

derive energy from fat without its passing through the carbohydrate stage. In either case the muscle would be availing itself of fat entering the body as carbohydrate. Therefore the fat would be a potential, if not an actual reserve of carbohydrate.

Oxygen.—Oxygen is stored to some extent in the body. At one time the conception was held that oxygen was stored actually in the tissues as so-called "intra-molecular" oxygen. That conception was founded on two others—(1) that a frog's muscle could contract in an atmosphere free from oxygen; and (2) that the contraction was essentially an oxidation. Now the idea of "intra-molecular oxygen" has been given up and we must look for no further store of oxygen than is to be found in the haemoglobin of the body. What is to be found there and in the lungs suffices to preserve consciousness for a few, perhaps two or three, minutes, and life for a somewhat longer time. The blood on the average is circulated round the body (at rest) rather more than once per minute and not so much as twice; on that circuit about one third of its oxygen is taken out. If therefore one assumes that all the blood goes round the body in 45 seconds and that there is enough oxygen in the blood for three circuits that would give oxygen enough for 135 seconds. In addition in such a case as that of drowning there is reserved oxygen in the lungs to the extent of what would supply the body for about two to three minutes. But if the body has no great store of oxygen on which to fall back, it has a considerable store of the material which transports oxygen and that is probably much more important. So far as is known about 80 per cent of the haemoglobin of the body is in circulation; the rest is stored, some in the spleen, some probably in the red marrow and the rest in situations as yet not fully explored.

The Principle of Specific Chemical Response.—There are a number of relatively simple chemical substances, any of which if injected into the body cause the body to produce some other substance which unites with and in a sense neutralises it. To give three examples:—If a fatty acid be administered to the alimentary canal, the acid will be absorbed by the villi, the cells of which will produce glycerine and the result will be a neutral fat. If on the other hand benzoic acid be administered it will get so far as the kidney and there the kidney cells will produce glycine, turning it into hippuric acid. Lactic acid similarly if thrust into the general circulation will be excreted as ammonium lactate, the ammonia being produced not by the cells of the body generally but by those, or certain of those, in the kidney. We have now arrived at the confines of the great subject of immunity —and perhaps outside the region of the present article.

The Principle of Dual Control.—The body has two ways of doing a great many things. Examples of this principle are so numerous as to be found in almost any system of the body. To take the point at which two of the most important systems of the body—the nervous and the respiratory systems—touch, let us consider the nervous control of respiration.

The essence of respiration is a rhythmic outflow of alternate inspiratory and expiratory impulses from the brain to the muscles concerned. That rhythm is probably, but not certainly, inherent in the brain itself, but it is regulated by influences which play upon the brain. These influences fall into two general categories—those which arrive along the nervous paths from the lungs and elsewhere and those which are borne to the brain in the blood stream.

An increase of total respiration may then take place in either of two ways—(a) many forms of irritation in the lung produce an increased total ventilation which is abolished by cutting the vagi and which may therefore be regarded as being due to special stimuli passing up along these nerves, (b) increase of carbonic acid in the blood even in the absence of nervous stimulation will so act upon the respiratory centre as to increase the total ventilation. During muscular exercise both the nervous and the chemical factors come into play; the nervous is the first to be initiated and therefore it may be regarded as the most sensitive; but even were it not involved a sufficient regulation could probably be carried out by the carbonic acid in the blood.

The respiratory centre furnishes another example. This time it is a combination of a nervous with a physical regulation. The facts are principally based on the observations of Professor Richet. If a dog lies down in the sun he will very shortly commence to pant in rapid, shallow respirations passing air over his tongue and through his respiratory passages. According to Professor Richet this tachypnoea is associated with an actual lowering of the body temperature and is due to stimuli from the warm skin reaching the respiratory centre via the sensory nerves. But even did not this nervous regulation of the body temperature take place another would supervene of perhaps a cruder character, for as soon as the body temperature began to rise, the warmer blood reaching the respiratory centre would itself produce an increased ventilation. Here again the nervous effect is the first to be invoked and presumably the more delicate.

The digestive system abounds with examples of duality. Of the three principal forms of food which are digested, carbohydrates, proteins and fats, the organs for the secretion of the digestive ferments are in all cases reduplicated. Starch is turned into sugar both by the saliva and by the pancreas, protein is broken down to the peptone stage both by the pepsin of the stomach and the trypsin of the pancreas, while to quote Leathes "two fat splitting enzymes are present in the intestinal contents, one being provided by the pancreatic juice and the other by the intestinal juice. . . . The action of the intestinal juice is however overshadowed by that of the pancreatic juice."

Not only are the ferments which effect digestion duplicated but there is a measure of duplication about the mechanisms responsible for their secretion. The processes of the alimentary canal are actuated, some by nervous stimuli, some by chemical, but in large measure by both. The secretion of saliva is entirely actuated by nervous stimuli; gastric juice is secreted largely as a result of nervous stimuli, but its flow is maintained by chemical bodies. In the secretion of pancreatic juice chemical stimuli play the more prominent part, nervous stimuli not however being entirely absent; whilst the secretion of the intestine is—so far as is known—due entirely to hormones. If the whole process from end to end be reviewed, some of the statements made about the respiratory centre are applicable. The process of digestion is initiated by nervous and maintained by chemical stimuli. As Dr. Anrep has pointed out, the further the food gets from the surface of the body, the less is it under the influence of the nervous, the more is it under the influence of the hormonal system.

The vascular system no less than the alimentary is subject to both hormones and to nervous stimuli, inasmuch as nearly all its parts are innervated by the sympathetic system (for adrenaline acts on the nerve endings of that system). Thus Florey has shown in the intestine of the dog, that a sudden sound will cause the mucous membrane to pale in a matter of a few seconds. If the nerves to this piece of intestine be severed the noise will still cause the intestine to pale, but after a much longer time—in about a quarter of a minute. The paling is in each case due to constriction of the small vessels. In the first case the constriction is initiated by nervous stimuli reaching the mucosa along the branches of the splanchic supply; in the second the blanching is due presumably to adrenaline secretion. The case is not however entirely parallel to that of the nervous and chemical government of the pancreas inasmuch as the adrenaline secretion is itself due to nervous stimulation, so that the reduplication is merely a reduplication of the paths by which the nervous system can control the calibre of the vessels.

What applies to the blood vessels applies, so far as the relative rôles of the nervous and the endocrine systems are concerned, to many other structures in the body which will at once occur to the reader. Many organs have not only a chemical and a nervous mechanism but also a double nervous supply. That however will be treated under the heading of ANTAGONISTIC NERVES.

Two organs in the mammals stand out as having no substitutes, the lungs and the generative organs, and in each case the fact is a little interesting because lower down in the animal kingdom that simplicity does not exist. Apart from the existence of gills, in the frog there is a cutaneous respiration so that it, even

in air, has two alternatives. As regards reproduction of course the most primitive form is simply by fission. Reproduction by fission exists in many forms of life collaterally with sexual reproduction, but in all the higher types of the animal kingdom it has been given up.

The Principle of Antagonistic Nerves.—There are numerous places in the body in which the actual condition of the organ at any moment is obtained by the balancing of antagonistic influences upon it. Four examples may be given.

(1) The rate of the heart beat is regulated by two nerves, one of which, the vagus, when stimulated, makes the heart go slower, while the other, the sympathetic, drives it faster. Normally its pace is neither so fast nor so slow as that of which it is capable, a fact to be accounted for by the balance of influences passing down the two nerves; if this balance alters the rate changes. (2) The diameter of the pupil of the eye is under the control of two nerves, one of which if stimulated dilates the pupil while the other constricts it; the actual size depends upon the relative influence of the two at any one moment. (3) The movements of the joints (say of the thigh joint) in walking are obtained by the balancing of the muscles which move the joint. It is not merely that alternately one set of muscles comes into action whilst the antagonistic set goes out of action: but each set is the whole time in a greater or less degree of tone. The whole action of the thigh depends upon the relative degree of the various muscles which exert an antagonistic action. (4) In the highest animals delicate manual movements have been secured by the antagonism of the thumb to the fingers, especially to the first finger.

The four examples cited, if examined, show little similarity in the mechanism by which the antagonism is produced. In the first the nerves act presumably in the same structure in the heart tissue. In the pupil the two sets of nerves act on different muscles. These do not pull directly against one another like men in a tug of war; the muscle which tends to close the pupil is a ring, that which tends to open it is radial. In the thigh you have definite groups of muscles pitted against one another and pulling the bone in opposite directions, while in the finger and thumb there are actually different organs.

Thirty years ago thought was focussed on antagonistic nerves because they were supposed to initiate opposite phases of protoplasmic activity in the organs which they supplied. All living matter was conceived as capable of anabolism (building up) and katabolism (breaking down); the slowing of the heart due to vagus stimulation was supposedly the expression of accentuated anabolic activity, the quickening of the heart due to sympathetic stimulation was held to indicate increased katabolism. Of the known cases of antagonistic nerves there are so few in which the two sets of fibres end in the same tissue that their connection with anabolic and katabolic activity has passed out of the picture.

It seems likely that their principal interest lies in the fact that by use of such antagonisms nature has built up a body capable of potentialities which it (the body) would not otherwise possess. By the balancing of the finger against the thumb more accurate and more delicate movements can be made than those of which either finger or thumb separately is capable. By the balancing of the thigh muscles against one another an accuracy of poise is secured which would not otherwise exist. The same is clearly true of the pupil, and had we the necessary discernment we could probably see the application of the general principle involved to the heart and blood vessels.

The Principle of Integrative Adaptation.—When the body is subjected to such adverse conditions that constancy of the composition of the blood cannot be maintained, the lack or excess of some one constituent may be of considerable gravity. In such circumstances some form of adaptation frequently takes place. This adaptation consists in an alteration in quite a number of factors each of which changes only a little though when the whole series of changes are integrated the net result is a very large degree of adaptation to the new environment. In such cases the body is not restored to its original degree of efficiency, but it has moved a considerable distance in that direction.

Examples may be drawn from the response of the body to exercise, to high altitudes, to anaemia and so forth, for which the articles on ANOXAEMIA, MUSCULAR EXERCISE, VASCULAR SYSTEM and ANAEMIA may be consulted. (J. BAR.)

PIACENZA (Lat. *Placentia*), a town and episcopal see of Emilia, Italy, the capital of the province of Piacenza, 42½ m. S.E. of Milan and 91 m. N.W. of Bologna by rail. Pop. (1921) 47,917 (town), 58,190 (commune). It lies on the Lombard plain, 217 ft. above sea-level, near the Po, which here is crossed by road and railway bridges each about 600 yd. long, just below the confluence of the Trebia. It is still surrounded by walls with bastions and fosse in a circuit of 4 miles. The cathedral was erected between 1122 and 1233, in the Lombard Romanesque style. The campanile is 223 ft. high. The entire edifice has been restored since 1898, and the frescoes by Guercino, Lodovico Caracci and Procaccini seem inappropriate to its severe style. In Sant' Antonino the deputies of the Lombard League swore to the conditions of peace ratified in 1183 at Constance. San Francesco is a Gothic edifice begun by the Franciscans in 1278. S. Savino, a Romanesque building of A.D. 903 (rebuilt in 1107 and restored in 1903) contains a mosaic pavement with curious representations, including one of a game of chess. S. Sisto (1499) once contained Raphael's Sistine Madonna, now in Dresden, sold in 1754 to Frederick Augustus III. Its place is occupied by a copy by Avanzini, and there are also several good intarsias by Bartolomeo da Busseto. Of the secular buildings the most interesting is the Palazzo Comunale, begun in 1281, built in marble and brick, with beautiful windows, one of the finest buildings of its kind in Italy. The Palazzo dei Tribunali and the Palazzo degli Scoti are early Renaissance brick buildings with terra-cotta decorations. The huge Farnese palace was begun after Vignola's designs by Margaret of Austria in 1558, but it was never completed, and since 1800 it has been used as barracks. The town has a motor car factory. It is an important agricultural centre. Petroleum wells have been bored hereabouts.

Piacenza was made a Roman colony in 218 B.C., in which year it afforded protection to the remains of the Roman army after the battle of the Trebia (*q.v.*). In 205 it withstood a siege by Hasdrubal. Five years later the Gauls burned it; and in 190 it was recruited with 3,000 families. In 187 it was connected with Ariminum and the south by the construction of the Via Aemilia. Later on it became a very important road centre; the continuation northwards of the Via Aemilia towards Milan, with a branch to Ticinum, crossed the Po there, and the Via Postumia from Cremona to Dertona and Genoa passed through it. Later still Augustus reconstructed the road from Dertona to Vada, and into Gallia Narbonensis, and gave it the name of Julia Augusta from Placentia onwards. The rectangular arrangement of the streets in the centre of the town, through which passes the Via Aemilia, is a survival from Roman times. Placentia is mentioned frequently as an important military point in Roman times. It was one of the leading members of the Lombard League. In 1447 the city was captured and sacked by Francesco Sforza. Having been occupied by the papal forces in 1512, it was in 1545 united with Parma (*q.v.*) to form an hereditary duchy for Pierluigi Farnese, nephew of Paul III. In 1796 it was occupied by the French. In 1848 Piacenza was the first town of Lombardy to join Piedmont, but was reoccupied by the Austrians till 1859.

PIANOFORTE. The group of keyed stringed musical instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music. During the 10th century the "organum" arose, an elemen-

tary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it, and the organ (*q.v.*), the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. About the same time arose a large stringed instrument, the organistrum, the parent of the now obsolete hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St. George de Boscherville, one of the strings was manipulated by means of a row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum.

FIG. 1.—PRIMITIVE CLAVICHORD (BEFORE 1460): EARLIEST EXISTING REPRESENTATION OF A KEYED STRINGED INSTRUMENT, FROM ST. MARY'S, SHREWSBURY

In the 11th century (the epoch of Guido of Arezzo [*q.v.*], to whom the beginning of musical notation is attributed), the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely of demonstrating the proportionate relations of the intervals, but also of initiating pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex monochords, which were constructed with scales so that four lines indicated authentic and the four plagal tones. This arrangement found great acceptance, for Aribo, writing about fifty years after Guido, says that few monochords were to be found without it. Aribo strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a *caprea* (wild goat). Jean de Muris (*Musica speculativa,* 1323) describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St. Mary's church, Shrewsbury. The latest date to which this figure may be attributed is 1460.

In the Weimar *Wunderbuch,* a MS. dated 1440 with pen and ink miniatures is given a "clavichordium" having 8 short and apparently 16 long keys. The artist has drawn 12 strings in a rectangular case, but no tangents are visible. A keyboard of balanced keys existed in the little portable organ known as the regal, so often represented in old carvings, paintings and stained windows. Vitruvius, *De architectura,* lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in *The Pneumatics of Hero of Alexandria,* translated by Bennet Woodcroft (London, 1851).

The name of regal was derived from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Atholl, and it bears the very late date of 1630. The Brussels regal may be as modern. (*See* Victor C. Mahillon, *Catalogue Descriptif* [1880], I. p. 320, p. 454.) We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the substitution of tangents (fixed in the ends of the balanced keys) for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. Ed. van der Straeten (*La Musique aux Pays Bas,* i. 278) reproduces a so-called clavichord of the 15th century from a MS. in the public library at Ghent. The treatise is anonymous, but other treatises in the same MS. bear dates 1503 and 1504. In the Weimar *Wunderbuch* is a pen-and-ink sketch of the "clavicimbalum" placed upon a table, in which we recognize the outline of the harpsichord, but on a smaller scale.

The earliest known record of the clavichord occurs in some rules of the minnesingers, dated 1404, preserved at Vienna. (*See* Ambros, *Geschichte der Musik* [1892], ii. 226.) The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicimbalum—the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite mediaeval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer.

There were two forms of the psaltery: (1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous Trionfo della Morte in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but according to Mersenne (*L'Harmonie universelle* [Paris, 1636], livre iii., p. 107), the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicimbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia. In 1472, chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St. Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood, as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic

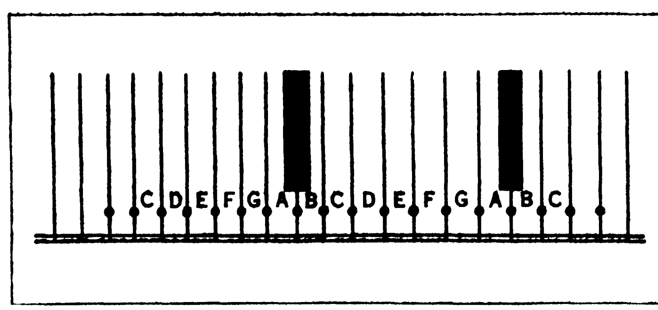

FIG. 2.—DIATONIC CLAVICHORD KEYBOARD (GUIDO'S SCALE) FROM VIRDUNG, BEFORE 1511, SHOWING THE SHORT KEYS B FLAT

organs with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und auszgezogen,* Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass stave to G above the treble. But Virdung tells

us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical *genera* of the Greeks—the diatonic, chromatic and enharmonic. But the last-named was not attained until equal temperament tuning was developed by J. S. Bach. Virdung gives woodcuts of the clavichordium, the virginal, the clavicimbalum and the clavicytherium. We reproduce three of them (figs. 3, 6 and 8), omitting the virginal as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive praxis musicae,* Strasbourg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the clavicytherium, are transposed, another cause of error.

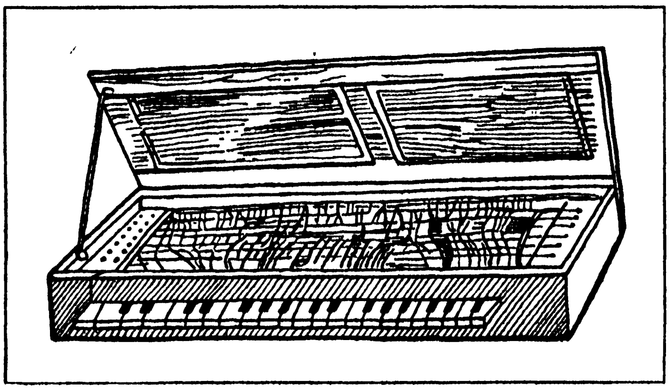

FIG. 3.—VIRDUNG'S CLAVICHORDIUM (1511): FACSIMILE WOODCUT, REVERSED TO CORRECT THE KEYBOARD

Still commonly known as monochord, Virdung's clavichord was really a box of monochords, all the strings being of the same length. We observe in this drawing (fig. 3) the short sound-board, which always remained a peculiarity of the clavichord, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of incidence for the tangents against the strings the keys were splayed, an expedient further rendered necessary by the "fretting"—three tangents being placed to give three different notes from each single group of strings tuned in unison. In the drawing the strings are merely indicated. The German for fret is *Bund,* and such a clavichord, in that language, is known as a "gebundenes Clavichord" both fret (to rub) and *Bund* (from *binden,* to bind) having been taken over from the lute or viol. The French and Italians employ "touche" and "tasto" (touch). Praetorius who wrote a hundred years later than Virdung, says two, three and four tangents were thus employed in stopping.

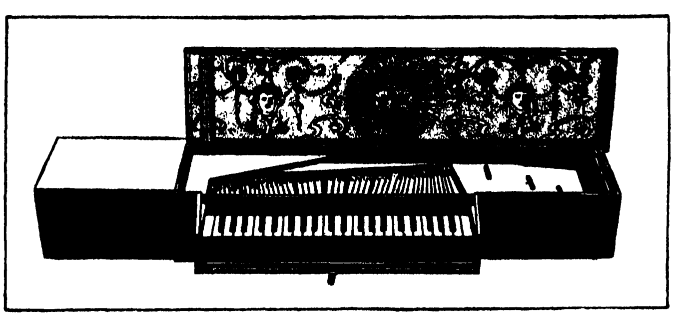

FIG. 4.—MANICORDO (CLAVICHORD) D'ELEONORA DI MONTALVO (1659); KRAUS MUSEUM, FLORENCE

Clavichords were made with double fretting up to about the year 1700—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach was now able to produce, in 1722, *Das wohltemperirte Clavier,* his famous collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned to what is now known as "equal temperament."

The oldest clavichord, here called manicordo (as French *manicorde,* from monochord), known to exist is that shown in fig. 4. The lowest octave is here already "bundfrei" or fret-free. The strings are no longer of equal length, and there are three bridges, divisions of the one bridge, in different positions on the sound-board. Mersenne's "manicorde" (*Harmonie Universelle,* Paris, 1636, p. 115), shown in an engraving in that work, has the strings still nearly of equal length, but the sound-board bridge is divided into five. The fretted clavichords made in Germany in the last years of the 17th century have the curved sound-board bridge, like a spinet. In the clavichord the tangents always formed the second bridge, deciding the pitch, besides acting as the sound exciters (fig. 5). The common damper to all the strings was a "list" of cloth, interwoven behind the tangents. As the tangents quitted the strings the cloth immediately stopped all vibration. As regards compass Handel's clavichord now in the museum at Maidstone (an Italian instrument dated 1726, and not fretted), has a compass of 3½ octaves (F to A).

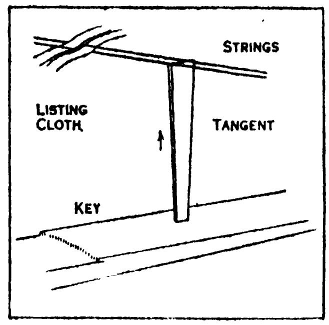

FIG. 5.—CLAVICHORD TANGENT
Showing position when front of keyboard is depressed; the tangent rises into contact with the strings and forms the end-point of the speaking length. The back string is kept from vibrating by means of the "Listing" cloth

The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin, but it remained longest in use in Germany—until even the beginning of the 19th century.

The next instrument described by Virdung is the virginal (*virginalis,* proper for a girl), a parallelogram in shape, having the same projecting keyboard and compass of keys as the clavichordium. Here we trace derivation from the psaltery, in that the sound-board covers the entire inner surface of the instrument and the disposition of the strings is triangular. The virginal in Virdung's drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavicimbalum, this is rectified, and the drawing, reversed on account of the keyboard, can be accepted as roughly representing the instrument so called (fig. 6). There would be no difference between the clavicimbalum and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinetta," a name

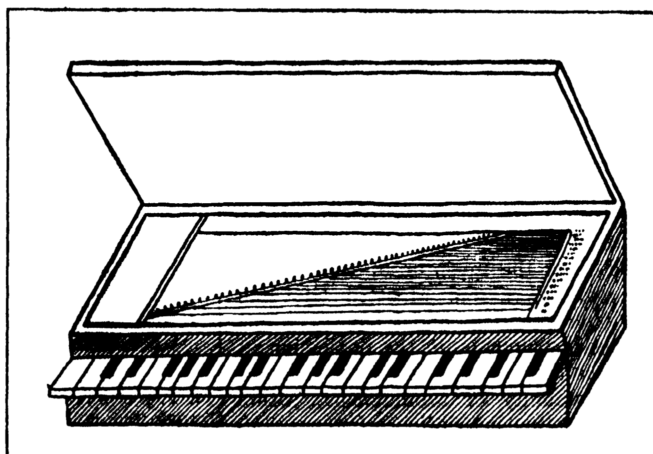

FIG. 6.—VIRDUNG'S CLAVICIMBALUM (SPINET), 1511; REVERSED FACSIMILE WOODCUT

unnoticed by Virdung or by his countryman Arnold Schlick, who, in the same year 1511, published his *Spiegel der Orgelmacher* (Organ-builders' Mirror), and named the clavichordium and clavicimbalum as familiar instruments. In the first place, the keyboard, beginning apparently with B natural, instead of F, makes the clavicimbalum smaller than the virginal, the strings in this arrangement being shorter; in the next place it is almost certain that the Italian spinet compass, beginning apparently upon a semitone, is identical with a "short measure" or "short octave" organ compass, a very old keyboard arrangement, by which the first three notes while appearing to be B, C and C sharp were tuned to G, C and A. The origin of this may be deduced from the psaltery and many representations of the regal, and its object appears to have been to obtain dominant basses for cadences, harmonious closes having early been sought for as giving pleasure to the ear.

Authority for this practice is to be found in Mersenne, who, in 1636, expressly describes it as occurring in his own spinet (*espinette*). We read (*Harmonie Universelle*, Paris, 1636, liv. 3, p. 107)—"Its longest string is little more than a foot in length between the two bridges. It has only thirty-one keys [*marches*] in its keyboard, and as many strings over its sound-board, so that there are five keys hidden [he now refers to the illustration] on account of the perspective—that is to say, three diatonic and two chromatic, of which the first is cut into two; but these sharps serve to go down to the third and fourth below the first step, C *sol* [tenor clef C], in order to go as far as the third octave, for the eighteen principal steps make but an eighteenth, that is to say, a fourth more than two octaves." Mersenne's statement sufficiently proves, first, the use in spinets as well as in organs of what we now call "short measure," and, secondly, the object of divided sharps at the lower end of the keyboard to gain lower notes.

As regards the kind of plectra earliest used we have no evidence. The little crow-quill points project from centred tongues in uprights of wood known as "jacks" (fig. 7), which also carry the dampers, and rising by the depression of the keys in front, the quills set the strings vibrating as they pluck them in passing. J. C. Scaliger in *Poetices libri septem* (1561, p. 51. c. 1.) states that the clavicimbalum and harpichordum of his boyhood were called spinets on account of those quill points (*ab illis mucronibus*), and attributes the introduction of the name "spinetta" to them from *spina*, a thorn, the meaning being extended to any small pointed object such as a quill. We will leave "harpichordum" for the present, but the early identity of "clavicimbalum" and "spinetta" is certainly proved. Scaliger's etymology remained unquestioned until Signor Ponsicchi of Florence discovered another, but less acceptable derivation. He found in a rare book entitled *Conclusione nel suono dell' organo, di D. Adriano Banchieri* (Bologna, 1608), the following passage, which translated reads: "Spinetta was thus named from the inventor of that oblong form, who was one Maestro Giovanni Spinetti, a Venetian; and I have seen one of those instruments, in the possession of Francesco Stivori, organist of the magnificent community of Montagnana, within which was this inscription—*Joannes Spinetvs Venetvs fecit, A.D. 1503.*" Scaliger's and Banchieri's statements may be combined, as there is no discrepancy of dates, or we may rely upon whichever seems to us to have the greater authority, always bearing in mind that neither invalidates the other. In France the word "épinette" still stands for both "spinet" and "chicken-house" which seems to strengthen the first-named theory. A spinet dated 1490 was shown at Bologna in 1888; another old spinet in the Conservatoire, Paris, is a pentagonal instrument made by Francesco di Portalupis at Verona, 1523.

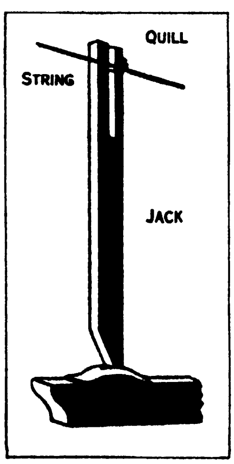

FIG. 7.—SPINET "JACK" Showing the quill which twangs the string on its upward journey, but, being hinged, slides quietly past on its return

The Milanese Rossi were famous spinet-makers, and have been accredited (*La Nobilità di Milano,* 1595) with the recessing of the keyboard, which had previously entirely projected; by this recessing a greater width was obtained for the sound-board. The spinets by Annibale Rosso at South Kensington, dated respectively 1555 and 1577, show this alteration, and may be compared with the older and purer form of one, dated 1568, by Marco Jadra (also known as Marco "dalle spinette," or "dai cembali"). The apparent compass of the keyboard in Italy generally exceeded four octaves by a semitone, E to F; but we may regard the lowest natural key as usually C, and the lowest sharp key as usually D, in these instruments, according to "short measure."

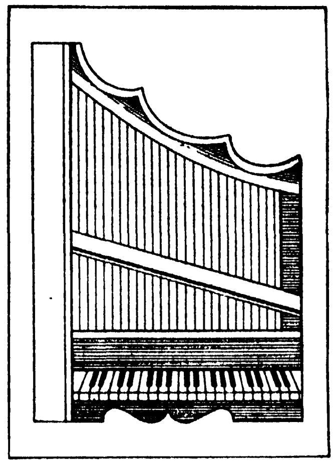

FIG. 8.—VIRDUNG'S CLAVICYTHERIUM (UPRIGHT HARPSICHORD), 1511; REVERSED FACSIMILE WOODCUT

The rectangular spinet, or "virginal," early assumed in Italy the fashion of the large "cassoni" or wedding chests. The oldest we know of in this style, and dated, is the fine specimen belonging to M. Terme which figures in *L'Art decoratif*. Virginal is not an Italian name; the rectangular instrument in Italy is "spinetta tavola." In England, from Henry VII. to Charles II., all quilled instruments (*stromenti di penna*), without distinction as to form, were known as virginals. It was a common name, equivalent to the contemporary Italian *clavicordo* and Flemish *clavisingel*. From the latter we arrive at the French *clavecin* the spinet being simply a "petit clavecin."

Mersenne (*op. cit.*, liv. iii., p. 158) gives three sizes for spinets —one $2\frac{1}{2}$ ft. wide, tuned to the octave of the "ton de chapelle" (a half tone above the present English medium pitch), one of $3\frac{1}{2}$ ft. tuned to the fourth below, and one of 5 ft. tuned to the octave below the first, the last being therefore tuned in unison to the chapel pitch. The octave spinet, of trapeze form, was known in Italy as "ottavina" or "spinetta di serenata." It had a less compass of keys than the larger instrument, being apparently three and two-third octaves, E to C—which by the "short measure" would be four octaves, C to C. These little spinets were placed upon the larger ones in performance and used to heighten the brilliant effect. In the double rectangular clavisingel of the Netherlands, in which there was a movable octave instrument, we recognize a similar intention. There is a fine spinet of this kind at Nuremberg. Praetorius illustrates the Italian spinet by a form known as the "spinetta traversa," an approach towards the harpsichord, the tuning pins being immediately over the keyboard. This transposed spinet, more powerful than the old trapeze one, became fashionable in England after the Restoration, when Haward, Keene, Slade, Player, Baudin, the Hitchcocks, Mahoon, Haxby, the Harrir family, and others made such "spinets" during a period for which we have dates from 1664 to 1784. Pepys

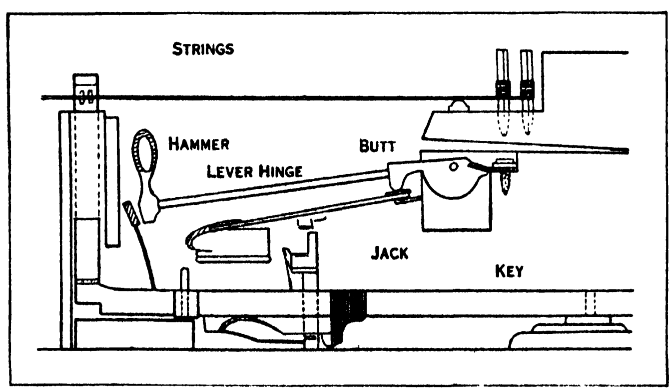

FIG. 9.—CRISTOFORI'S ESCAPEMENT ACTION (1720)
The hinged lever, when struck by the jack, transmits the blow to the butt, thus having the effect of throwing the hammer towards the strings

bought his "Espinette" from Charles Haward for £5, July 13, 1664. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the naturals.

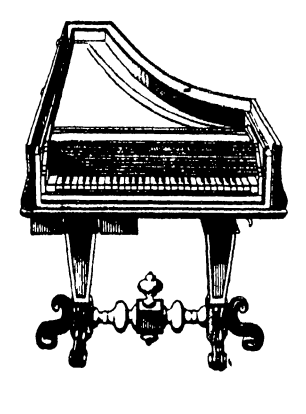

FIG 10—CRISTOFORI'S PIANO E FORTE (1726), KRAUS MUSEUM, FLORENCE

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della musica antica e moderna,* Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp, proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as derived from the harp and psaltery respectively

The Latin name "clavicimbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo and clavecin Much later, after the restoration of the Stuarts, "harpichord" was accepted and naturalized in England as harpsichord, which we will define as the long instrument with quills, shaped like a modern grand piano. We can point out no long instrument of this kind so old as the Roman cembalo at South Kensington. The outer case is of finely tooled leather. It has a compass of nearly four octaves, E to D, and the natural keys are of boxwood.

The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este by Count Valdrighi of Modena (*see* Van der Straeten, vi., 122), we are disposed to regard, not as an anticipation of Cristofori's subsequent invention of the pianoforte, but as an ordinary cembalo with power to shift by a stop, from two unisons (forte) to one string (piano), at that time a Flemish practice, and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition.

About the year 1600, when accompaniment was invented for monody, large cembalos were made for the orchestras to bring out the bass part, the performer standing to play. Such an instrument was called "archicembalo," a name also applied to a large cembalo, made by Vito Trasuntino, a Venetian, in 1606, intended by thirty-one keys in each of its four octaves, to restore the three genera of the ancient Greeks.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century We find them imported into England The following citations, quoted by Rimbault in his *History of the Pianoforte,* are from the privy purse expenses of King Henry VIII.

"1530 (April). Item the vj daye paied to William Lewes for ii payer of virginalls in one coffer with iiii stoppes brought to Grenewiche iii. li. And for ii payer of virginalls in one coffer brought to the More other iii. li."

Now the second instrument may be explained ("virginals" meaning any quilled instrument) as a double spinet, like that at Nuremberg by Martin van der Beest, the octave division being movable. But the first cannot be so explained; the four stops can only belong to a harpsichord, and the two pair instrument to a double-manual Again from the inventory after the king's death (*see* Brit. Mus. Harl. MS. 1419) fol. 247—

"Two fair pair of new long Virginalls made harp-fashion of Cipres, with keys of ivory, having the King's Arms crowned and supported by his Grace's beastes within a garter gilt, standing over the keys."

This is probably another double keyboard harpsichord. We read in an inventory of the furniture of Warwick Castle, 1584, "a faire paire of double virginalls," and in the Hengrave inventory, 1603, "one great payre of double virginalls." Hans Ruckers, the great clavisingel maker of Antwerp, lived too late to have invented the double keyboard and stops, evident adaptations from the organ, and the octave string was already in use when he began his work. Until the last harpsichord was made by Joseph Kirkman, in 1798, scarcely an instrument of the kind was constructed, except in Italy, without the octaves. The harpsichord as known throughout the 18th century, with "piano" upper and "forte" lower keyboard, was the invention of Hans Ruckers's grandson, Jean Ruckers's nephew, Jan Couchet, about 1640 Before that time the double keyboards in Flemish harpsichords were merely a transposing expedient, to change the pitch a fourth, from plagal to authentic and vice versa, while using the same groups of keys.

After the Antwerp make declined, London became pre-eminent for harpsichords—the representative makers being Jacob Kirckmann and Burckhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirckmann continued through marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time, by which Haendel became Handel, and Schmidt Smith, Kirckmann dropped his final *n* and Tschudi became Shudi, but he resumed the full spelling in the facies of the splendid harpsichords he made in 1766 for Frederick the Great, which are still preserved at Potsdam By these great makers the harpsichord became a larger, heavier-strung and more powerful instrument, and fancy stops were added to vary the tone effects To the three shifting registers of jacks were added the "lute," the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge, and the "harp," a muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used, the left-hand one a combination of a unison and lute.

The right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius, to whom also the harp stop may be rightly attributed The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (?Haward) as early as 1676, as we learn from Mace's *Musick's Monument,* p. 235. The French makers preferred a kind of knee-pedal arrangement, known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine" As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and becoming in England a favourite addition to harpsichords, was early transferred to the organ, replacing the rude "nag's-head" swell.

To keep his collection of musical instruments in playing order Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia,* a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte* We learn from it that in 1709 Cristofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer-butt The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring Moreover, the hammer had each time to be raised the entire distance of its fall There are, however, two pianofortes by Cristofori, dated respectively 1720 and

1726, which show a much improved construction, for the whole of an essential piano movement is there. The earlier instrument (now in the Metropolitan Museum, New York) has undergone considerable restoration, but the 1726 one, which is in the Kraus Museum at Florence, retains the original leather hammer-heads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have

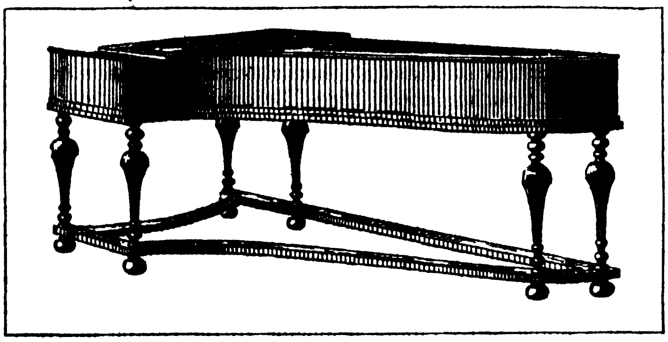

FIG. 11.—SILBERMANN FORTE PIANO (1746), STADTSCHLOSS, POTSDAM

the "check" (Ital. *paramartello*), which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings.

Thicker stringing, to withstand even Cristofori's light hammers, demanded in its turn a stronger framing than the harpsichord had needed. Accordingly to make his structure firm Cristofori considerably increased the strength of the block which holds the tuning-pins, and as he could not do so without materially adding to its thickness, he adopted the bold expedient of inverting it; driving his wrest-pins, harp-fashion, through it, so that tuning was affected at their upper, while the wires were attached to their lower, ends. Then, to guarantee the security of the case, he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils, but did not found a school of Italian pianoforte-making. The 1711 essay of Scipione Maffei was translated into German, in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavichord maker (*see* Dr. Oscar Paul's *Geschichte des Claviers*, Leipzig, 1868). Incited by this publication, and perhaps by having seen in Dresden one of Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz., that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it.

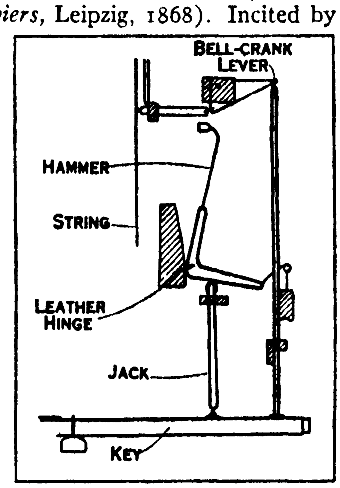

FIG. 12.—FREDERICI'S UPRIGHT GRAND PIANO ACTION (1745)
In the museum of the Brussels Conservatoire. The leather hinge allows the bellcrank lever to convert the upward throw of the jack into a forward motion of the hammer towards the string

Whatever Silbermann's first experiments were based upon, he ultimately adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys and the style of joinery of the case. In the Silbermann grand pianofortes at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank and action complete. Fig. 11 represents the instrument on which J. S. Bach played in the Stadtschloss, Potsdam.

It has been repeatedly stated in Germany that Frederici, of Gera in Saxony, an organ builder and musical instrument maker, invented the square or table-shaped piano, the "fort bien," as he is said to have called it, about 1758–60. No square piano by this maker is forthcoming, though an "upright grand" piano, made by Domenico del Mela in 1739, with an action adapted from Cristofori's has been discovered by Signor Ponsicchi of Florence. Victor

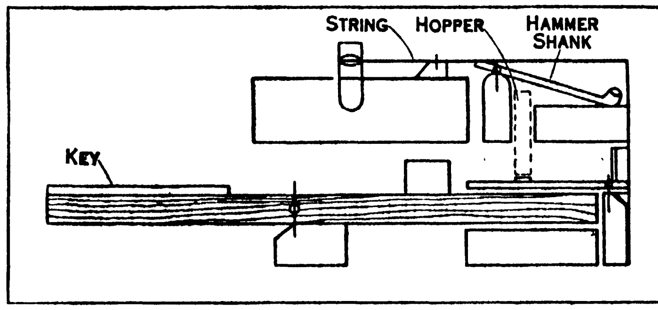

FIG. 13.—SCHROETER'S MODEL FOR AN ACTION (1721): SHOWING THE KEY READY TO LIFT THE HOPPER, AND MAKE IT STRIKE THE HAMMER SHANK

Mahillon of Brussels, however, acquired a Frederici "upright grand" piano, dated 1745. In Frederici's upright grand action (fig. 12) we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg; a fact which needs further elucidation. We note here the earliest example of the leather hinge, afterwards so common in piano actions. An attempted combination of harpsichord and pianoforte appears very early. The English poet Mason, the friend of Gray, bought such an instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

It was only under date of 1763 that Schroeter published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marpurg's *Kritische Briefe* (Berlin, 1764). Now, immediately after, Johann Zumpe, a German in London, who had been one of Shudi's workmen introduced (there is some tradition that Mason had to do with the invention of it) a "square" piano, which was destined to become the most popular domestic instrument. Zumpe was in fact not the inventor of the square piano, which appears to have been well known in Germany before his date, a discovery made by Mr. George Rose. In Paul de Wit's Musical Instrument Museum—formerly in Leipzig, afterwards transferred to Cologne—there is a small square piano by Hildebrandt 27 in. long 10 in. wide and $4\frac{1}{2}$ in high, having a contracted keyboard of 3 octaves and 2 notes. The action of this small instrument is practically identical in every

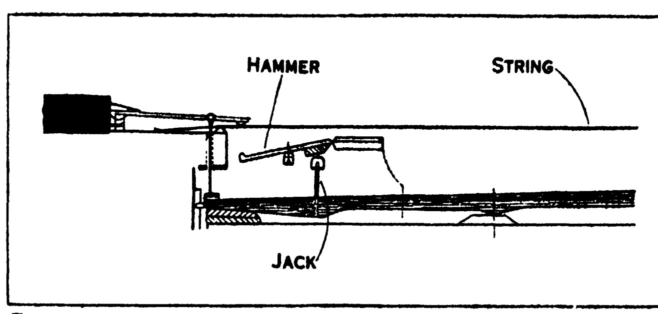

FIG. 14.—ZUMPE'S SQUARE PIANO ACTION (1765): GIVING A DIRECT BLOW WITH THE JACK NEAR THE BUTT END OF THE HAMMER

detail with that of the square pianofortes made much later by Zumpe (Paul de Wit, *Katalog des musikhistorischen Museums*, Leipzig, 1903. No. 55, illustration, p. 38). Inside is inscribed: "Friedrich Hildebrandt, Instrumentenmacher in Leipzig, Quergasse," with four figures almost illegible. Paul de Wit refers the instrument to the middle of the 18th century. It has all the

appearance of being a reduced copy of a well-established type, differing very little from the later models.

Burney tells us all about Zumpe; and his instruments still existing would fix the date of the first at about 1765. Fétis narrates, however, that he began the study of the piano on a square piano made by Zumpe in 1762. In this simple action (fig. 14) we have the nearest approach to a realization of Schroeter's idea. It will be noted that Schroeter's damper (fig. 13) would stop all vibration at once. This defect is met by Zumpe's "mopstick" damper.

Another piano action had, however, come into use about that time or even earlier in Germany The discovery of it in the

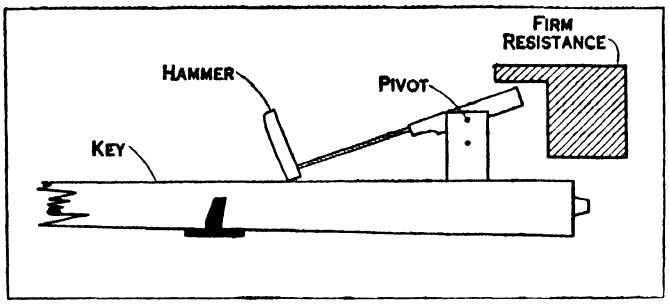

FIG. 15—EARLIEST KNOWN PIANO ACTION ON THE GERMAN PRINCIPLE OF ESCAPEMENT, WHEREBY THE PIVOT RISES WITH THE KEY AND THROWS THE BUTT AGAINST A FIRM RESISTANCE

simplest form is to be attributed to V. C. Mahillon, who found it in a square piano belonging to Henri Gosselin, painter of Brussels (fig. 19). The principle of this action is that which was later perfected by the addition of a good escapement by Stein of Augsburg, and was again later experimented upon by Sebastian Erard Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and permit of its transformation into a square piano It will be observed that the hammer is, as compared with other actions, reversed, and its pivot rises with the key, necessitating a fixed rail against which the hammer butt strikes. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind. He had found the instrument that for the rest of his short life replaced the harpsichord. V. C. Mahillon secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action (fig. 16), two unisons, and the knee pedal.

Mozart's own grand piano, preserved at Salzburg, and the two grand pianos (the latest dated 1790) by Huhn of Berlin, preserved

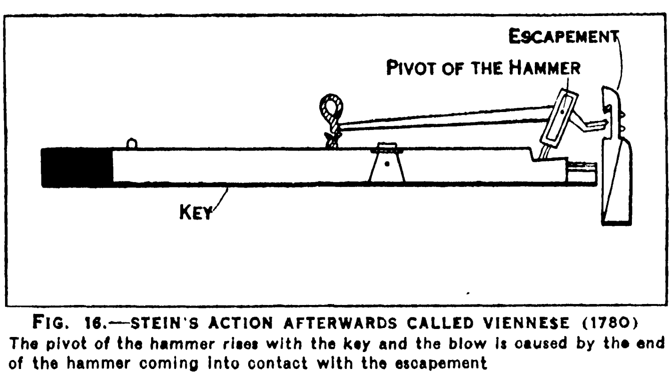

FIG. 16.—STEIN'S ACTION AFTERWARDS CALLED VIENNESE (1780)
The pivot of the hammer rises with the key and the blow is caused by the end of the hammer coming into contact with the escapement

at Berlin and Charlottenburg, follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as *celeste*, which no doubt Stein had also. The wrest-plank is not inverted; nor is there any imitation of Cristofori. Stein's instrument was accepted as a model in Berlin as well as Vienna, to which city his business was transferred in 1794 by his daughter Nanette, known as an accomplished pianist and friend of Beethoven, who at that time used Stein's pianos. Streicher, a pianist, who married Nanette, further improved the Viennese instrument, famous for its lightness of touch.

We will quit the early German piano with an illustration (fig. 17) of a square piano action in an instrument made by Johann Gottlob Wagner of Dresden in 1783, and embodying the Cristofori principle rather than the Viennese.

Burney, who lived through the period of the displacement of the harpsichord by the pianoforte, is the only authority to whom

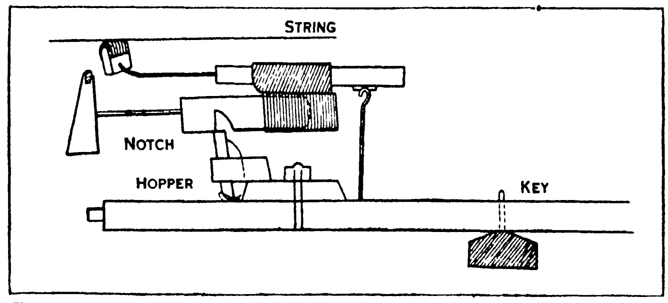

FIG 17.—GERMAN SQUARE ACTION (1783): ESCAPEMENT IS EFFECTED AT THE POINT WHERE THE HOPPER FALLS INTO THE NOTCH PIANO BY WAGNER, DRESDEN

we can refer as to the introduction of the latter instrument into England He tells us without giving the exact date that the first hammer harpsichord that came to England was made by an English monk at Rome, a Father Wood, for an English gentleman, Samuel Crisp of Chesington; the tone of this instrument was superior to that produced by quills, with the advantage of *piano* and *forte* expression so that, although the touch and mechanism were imperfect, yet in a slow movement like the "Dead March" in *Saul* it excited wonder and delight Fulke Greville afterwards bought this instrument for 100 guineas, and it remained unique in England for several years, until Plenius, the inventor of the lyrichord, made a pianoforte in imitation of it In this instrument the touch was better, but the tone was inferior Plenius produced his lyrichord, a *sostenente* harpsichord, in 1745, and Mason imported a pianoforte ten years later Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success Of these Americus Backers (d. 1776), said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, based upon Cristofori's, and may have made the instrument referred to in an old play-bill of Covent Garden in Messrs Broadwoods' possession, dated May 16, 1767, which has the following announcement —

"End of Act I Miss Brickler will sing a favourite song from *Judith*, accompanied by Mr Dibdin on a new instrument call'd Piano Forte"

Backers's "Original Forte Piano" was played at the Thatched House in St. James's Street, London, in 1773 Ponsicchi has found a Backers grand piano at Pistoria, dated that year.

The escapement lever is suggested by Cristofori's first action, to which Backers added a contrivance for regulating it by means of a button and screw (*see* fig. 18). The check is from Cristofori's second action John Broadwood and Robert Stodart were friends, Stodart having been Broadwood's pupil; and they were the assistants of Backers in the installation of his invention On his deathbed he commended it to Broadwood's care, but Stodart appears to have been the first to advance it—Broadwood being probably held back by his partnership with his brother-in-law, the son of Shudi, in the harpsichord business (The elder Shudi had died in 1773.) Stodart soon made a considerable reputation with his "grand" pianofortes, a designation he was the first to give them. In Stodart's grand piano we first find an adaptation from the lyrichord of Plenius, of steel arches between the wrest-plank and belly-rail, bridging the gap up which the hammers rise These are not found in any contemporary German instruments, but may have been part of Backers's. Zumpe's small square piano had met with great success, he was soon enabled to retire, and his imitators, who were legion, continued his model with its hand stops for the dampers and sourdine, with little change but that

which straightened the keys from the divergences inherited from the clavichord.

John Broadwood took this domestic instrument in hand to improve it, and in the year 1780 succeeded in entirely reconstructing it. He transferred the wrest-plank and pins from the right-hand side, as in the clavichord, to the back of the case, an

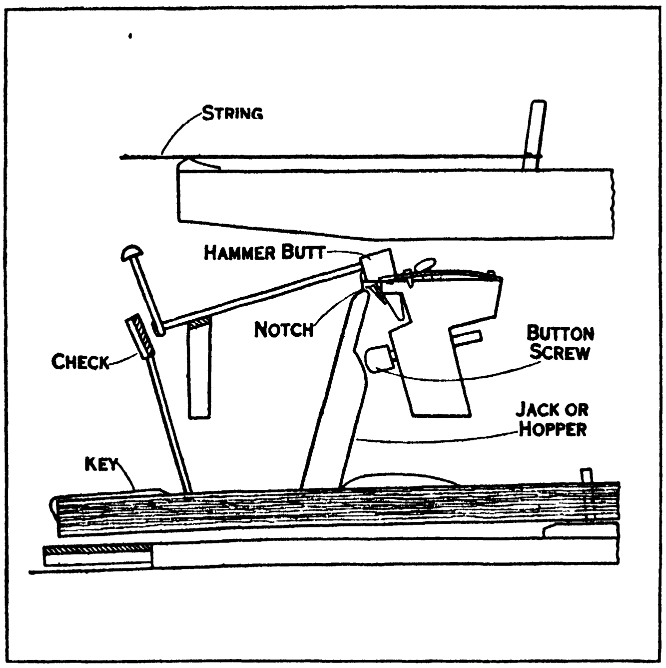

FIG. 18.—GRAND PIANO ACTION (1776). THE "ENGLISH" ACTION OF AMERICUS BACKERS
The button screw throws the jack out of the notch in the butt after making the blow; improved by Messrs. Collard (1835), who reversed the lever and hammer butt

improvement universally adopted after his patent, No. 1379 of 1783, expired. In this patent we first find the soft and sustaining pedals, since universally accepted, but at first in grand pianofortes only. John Geib patented (No. 1571 of 1786) the hopper with two separate escapements, one of which was soon adopted in the "grasshopper" of the square piano, it is believed by Geib himself;

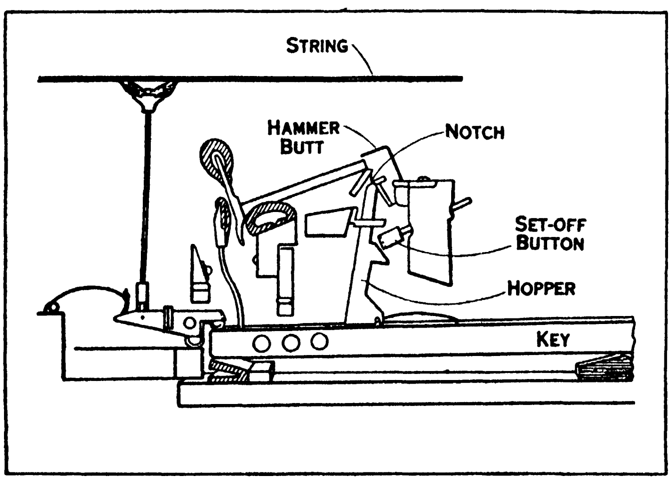

FIG. 19.—BROADWOOD'S GRAND PIANO ACTION (1884). ENGLISH DIRECT MECHANISM
The hopper is thrown from the notch in the butt, by the slanting blow given by the set-off button when the hopper rises

and Petzold, a Paris maker, appears to have taken later to the escapement effected upon the key.

To return to John Broadwood—having launched his reconstructed square piano, he next turned his attention to the grand piano to continue the improvement of it from the point where Backers had left it. He called in the aid of professed men of science—Tiberius Cavallo, who in 1788 published his calculations of the tension, and Dr. Gray, of the British Museum. The problem was solved by dividing the sound-board bridge, the lower half of which was advanced to carry the bass strings, which were still of brass. Even the first attempts to equalize the tension and improve the striking-place were successful in improving the tone greatly. To please Dussek, Broadwood in 1791 carried his five-octave, F to F, keyboard, by adding keys upwards, to five and a half octaves, F to C. In 1794 the additional bass half octave to C, which Shudi had first introduced in his double harpsichords, was given to the piano.

The first square piano made in France is said to have been constructed in 1776 by Sebastian Erard, a young Alsatian. In 1786 he came to England and founded the London manufactory of harps and pianofortes bearing his name. Erard took out his first patent for a "repetition" action in 1808. He did not, however, succeed in producing his famous repetition or double escapement action until 1821; it was then patented by his nephew Pierre Er-

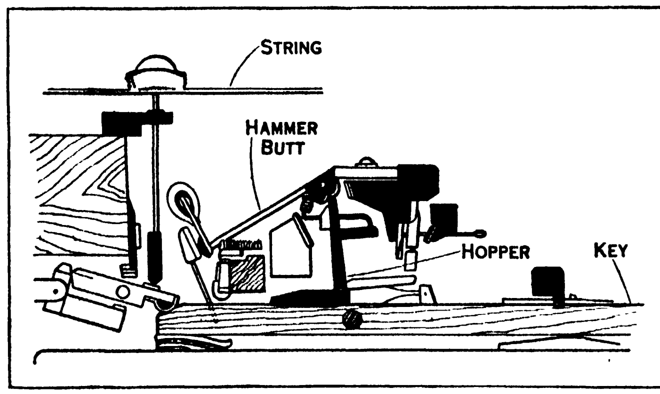

FIG. 20.—COLLARD'S GRAND PIANO ACTION (1884); ENGLISH ACTION, WITH REVERSED HOPPER AND CONTRIVANCE FOR REPETITION ADDED, OPERATING UNDER THE BUTT

ard. When the patent expired in England in 1835 it had proved a loss from the difficulties of carrying out the invention. This induced the House of Lords to grant an extension of the patent.

Erard invented in 1808 an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal, through holes in which the strings are made to pass, bearing against the upper side. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, Bord.

The first to see the importance of iron combined with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, known as the inventor of the ever-pointed pencil. He was living at Philadelphia, U.S.A., when he invented and first produced the familiar upright pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish piano-maker, had in 1798 tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument is in a complete iron frame, independent of the case; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the tall cabinet pianoforte, with hinged sticker action, in 1807. All that he could, however, patent in it was the simple damper action, turning on a pivot to relieve the dampers from the strings. The next

steps for producing the short or cottage upright piano were taken by Robert Wornum, who in 1811 produced a diagonally, and in 1813 a vertically, strung instrument. Wornum's improved crank action (fig. 23) was not complete until 1826, when it was patented for a cabinet piano; but it was not really introduced until three years later, when Wornum applied it to his little "piccolo" The principle of this centred lever check action was introduced

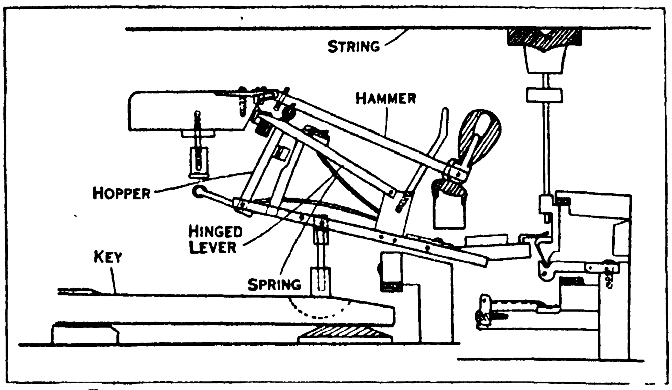

FIG 21—ERARD'S DOUBLE ESCAPEMENT ACTION (1821)
The escapement of repetition is effected by a spring pressing the hinged lever upwards, to allow the hopper which delivers the blow to return into position, before the key has risen again

into Paris by Pleyel and Pape, and thence into Germany and America (Pleyel exhibited a small upright piano in Paris in 1827, but Pierre Erard did not turn his attention to upright pianos until 1831.)

Early in the 19th century William Allen, a young tuner in the employ of the Stodarts, devised a metal system of framing intended primarily for compensation, but soon to become, in other hands, a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by atmospheric changes by compensating tubes and plates of the same metals, guaranteeing their stability by a cross batoning of stout wooden bars and a metal bar across the wrest-plank Allen consulted Stodart's foreman, Thom; and Allen and Thom patented the invention in January 1820 The firm of Stodart at once acquired the patent

We now arrive at an important epoch in pianoforte construction—the abolition of the wooden construction in favour of a combined construction of iron and wood, the former material gradually asserting pre-eminence. Allen's design is shown in fig 24. The long bars are really tubes fixed at one end only; those

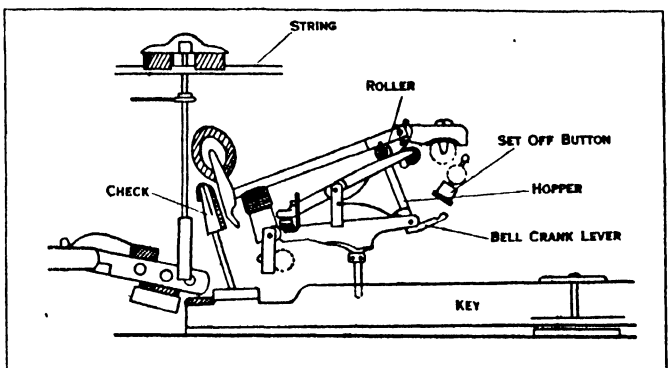

FIG 22.—STEINWAY'S GRAND PIANO ACTION (1884)
The double escapement as in Erard's (fig. 21) but with shortened balance and usual check. The hopper escapes from under the roller owing to the bell-crank lever coming into contact with the set-off button

of iron lie over the iron or steel wire, while those of brass lie over the brass wire, the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings without danger to the durability of the case and frame In 1821, a fixed iron string-plate, the invention of one of Broadwood's workmen, Samuel Hervé, was applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even resistance to the tension of the strings and the reduction of their length behind the bridge. Long iron resistance bars were experimented on as substitutes for the wooden bracing by Joseph Smith in 1798; but to James Broadwood belongs the credit of trying them first above the sound-board in the treble part of the scale in 1808, and again in 1818; he did not succeed, however, in fixing them properly. Sebastian and Pierre Erard seem to have been first in the field in 1823 with a complete system of nine resistance bars from treble to bass; with a simple mode of fastening them through the sound-board to the wooden beams beneath James Broadwood, by his patent of 1827, claimed the combination of string-plate and resistance bars, which was clearly the completion of the wood and metal instrument, differing from Allen's in the resistance being fixed Broadwood left the bass bars out, but added a fourth bar in the middle to the three in the treble he had previously used But the weight of the stringing was always increasing, and a heavy close copper covering of the bass strings had become general. The resistance bars were increased to five, six, seven, eight and, as we have seen, even nine, according to the ideas of the different English and French makers who used them in their pursuit of stability.

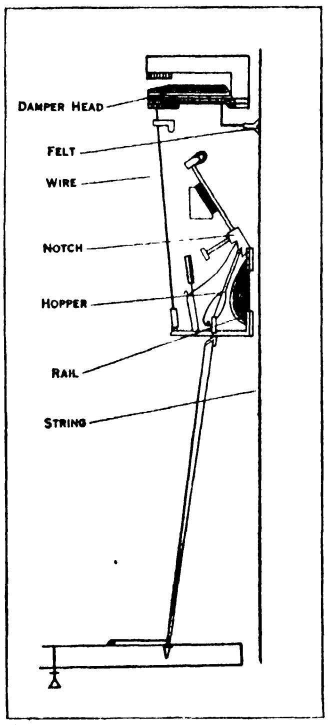

FIG 23—WORNUM'S UPRIGHT ACTION (1826), ORIGINAL OF THE NOW UNIVERSAL ACTION IN UPRIGHT PIANOS
The Hopper in its ascent drove the hammer forward at the same time contacting the rail which threw the upper end of the hopper out of the notch forming what is known as the escapement. Meanwhile the damper-head is raised by the wire, and the felt is taken from the string

A method of fastening the strings on the string-plate depending upon friction, and thus dispensing with "eyes," was a contribution of the Collards, who had retained James Stewart, a man of considerable inventive power, who had been in America with Chickering This invention was introduced in 1827 Between 1847 and 1849 Mr Henry Fowler Broadwood, grandson of John Broadwood, invented a grand pianoforte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found After the Great Exhibition of 1851 he employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar After 1862 he covered his wrest-plank with a thick plate of iron into which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string.

The introduction of iron into pianoforte structure was differently and independently effected in America, the fundamental idea there being to use a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphaeus Babcock was the pioneer of this kind of metal construction. He also cast an iron ring for a square piano in 1825, which, although not a success, gave the clue to a single casting resistance framing, successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878 Meyer's idea was improved upon by Jonas Chickering (1797–1853) of Boston, who applied it to the grand piano as well as to the square, since which time this prin-

ciple has been universally adopted.

We have now to consider over- or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century clavichords were sometimes overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Gerock & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanician in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano, made by Lichtenthal of St. Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. Later, in 1855, Henry Engelhard Steinway (originally Steinweg; 1797–1871), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading to important results.

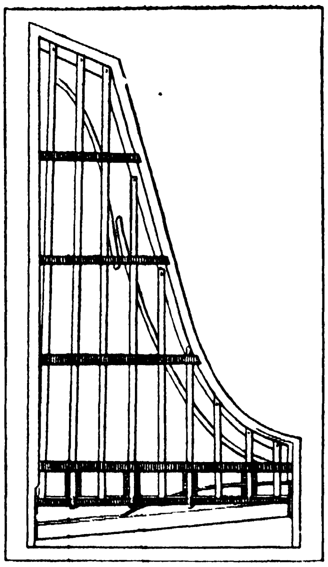

FIG. 24.—ALLEN'S COMPENSATING GRAND PIANO (1820)' THE FIRST COMPLETE METAL FRAMING SYSTEM APPLIED OVER THE STRINGS

It would be inaccurate to say that no outstanding developments have taken place in pianoforte construction during the last fifty years, but few new principles have been discovered, and improvement has taken place almost entirely in the direction of applying in greater and greater measure scientific knowledge to methods and practices previously empirical (*see* PIANOFORTE MANUFACTURE) thus resulting in improvement in tonal volume and purity.

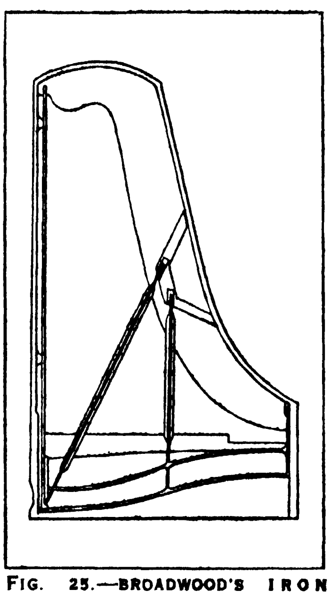

FIG. 25.—BROADWOOD'S IRON GRAND PIANO (1884), HAVING COMPLETE IRON FRAME WITH DIAGONAL RESISTANCE BAR

Summing up matters it may be said that the modern pianoforte retains six important characteristics of the clavichord, in that it has an independent sound-board (*i.e.*, the ends of the strings are not fastened to it), dampers to prevent vibration of the strings not in use, "listing" cloth to deaden the vibration from the ends of the strings beyond the bridges, groups of three strings tuned in unison and a tone production which depends upon a blow instead of a plucking (as in the spinet and harpsichord).

Five of the ideas developed in the harpsichord have also survived or have been revived from time to time, namely, the sustaining pedal, the celeste felt for soft playing, the transposing keyboard, the soft stop for practising very quietly, and the double manual (viz., as recently introduced by Emanuel Moór).

As regards the sustaining pedal the importance of this cannot be over-estimated, for not only does it allow of harmonies being maintained when necessary without holding the keys down, but it also modifies the tone quality by allowing all strings to take part simultaneously by means of their resonance. Moreover the sound-board is encouraged to increase its amplitude of vibration, thus increasing the tonal volume, which in skilful hands can be made to reach a maximum intensity of over twenty times that of the most powerful harpsichord. Contrariwise, the tone can be attenuated and diminished by means of the soft pedal, which brings the hammers nearer the strings, or (as in the case of grand pianos) shifts the hammers so that they strike two instead of three strings. The "celeste" pedal and "soft stop" devices both involve the introduction of a strip of felt between the strings and the hammers at the point of contact, thus reducing the force of the blow. For school pianos, used for practising almost continuously throughout the day, the soft stop is a most useful adjunct and when properly designed need not interfere unduly with the touch of the instrument.

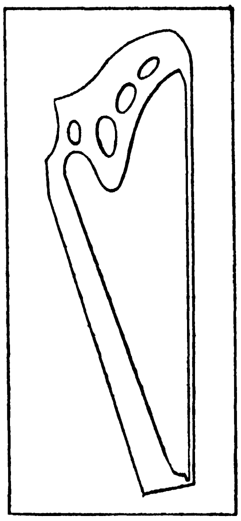

FIG. 26.—MEYER'S METAL FRAME FOR A SQUARE PIANO (1833)

The transposing device, in turn, is now becoming popular on player pianos, which are being increasingly used for accompaniment purposes. It is obviously a great advantage to be able to suit the requirements of any particular voice in this way and the means of doing so are easily provided. In the ordinary instrument on the other hand it is difficult to keep transposing devices in perfect order owing to the necessity for shifting the keys relative to the action, a movement which upsets the delicate regulation of the repetition, and renders the device unsatisfactory.

Finally, the double keyboard, as invented by Emanuel Moór, represents a really important development, extending the resources of both performer and composer to an astonishing degree. Such a revolutionary departure will doubtless take time to become commercially possible, but the most weighty musical opinion is entirely in its favour. Briefly stated, the second keyboard lies just behind and above the normal standard notes, and operates those strings which are an octave higher. Consequently it is possible to play extended chords, arpeggios and double octaves with great facility. There is also an octave coupler which further increases the possibilities of the instrument from the point of view of volume. To what extent the principle will ever secure general adoption it would be rash to prophesy, but as to its ingenuity and musical value there is no room for doubt.

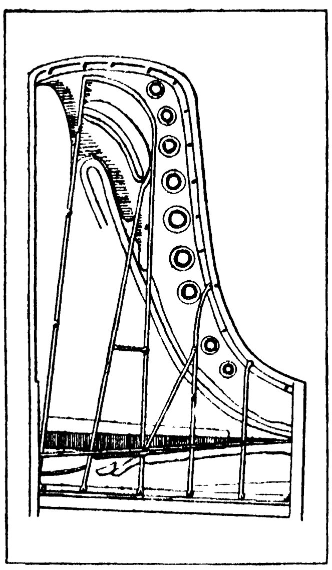

FIG. 27.—STEINWAY'S GRAND PIANO (1884), A METAL FRAMING IN A SINGLE CASTING AND OVERSTRUNG

The principles discovered in the early actions (Erard 1821 and Robert Wornum 1826) still stand firm, and all subsequent improvements have been built thereon. The separate parts of the modern action are produced by automatic machinery, and assembled by hand with great skill and accuracy. The pianoforte

manufacturer has long recognized the advisability of allowing this important component to be made for him by specialists, the hammers and hammer shanks being fitted after the action has been installed.

Present-day development is towards a greater tonal volume without altering the weight or depth of touch, any increase in which is a serious handicap to the virtuoso. The sound-board is made as sensitive as possible, supported in a rigid frame-work which absorbs little or no energy from the board at its edges. The modern sound-board sustains a continual down-pressure from the strings of nearly half a ton, whereas the early grand pianos had scarcely a hundred-weight pressure thereon. The string tension has tripled (from 60 to 180 lb. per string in some instances) with the ability of the wire drawers to supply stronger and stronger wire, and the iron founder has had to devise castings which stand a total stress of 16 tons and upwards without occupying too much room, or covering too large a portion of the surface of the sound-board. Some early makers had the mistaken idea that an iron structure entailed the production of a "metallic" tone in the instrument; but those who adhered to the use of the wooden frame were soon left behind, mainly owing to the extreme susceptibility of the pitch of such pianos to temperature and humidity changes, which rendered the tuning very unstable.

FIG. 28.—A WEBER PIANO SHOWING THE EMANUEL MOÓR DUPLEX COUPLER KEYBOARD

As regards the future, one of the most interesting of the possible further developments which have been mooted is the electrical agitation of the strings so as to secure a sustained tone instead of one which rapidly diminishes after the moment of impact. In Germany experiments are being made with quarter-tone scales, which may or may not develop a new technique for composers and performers, but the standard key-board of to-day has such a wide range of frequencies (from 27 to 4,176 vibrations per second) that it is unlikely that it will be superseded for many years to come. PIANOFORTE MANUFACTURE. There are eighty-eight notes in the full compass keyboard of the pianoforte, which gives a range of 7¼ octaves. The fifty-second note from the bass end of the scale is called "Pitch C," and serves as the standard from which all the others are tuned. Since each note has to vibrate twice as fast as the note of the same name an octave below, and there are twelve semitones to the octave, it follows that the semitone ratio from note to note must be the twelfth root of 2, namely 1·05946, which is a geometrical progression giving the now generally adopted "equal temperament" tuning. Purely mathematical considerations make it essential that the string lengths should also proceed in geometrical progression, but in a slightly smaller octave ratio than 2:1. In Germany the ratio most favoured is 1·875:1, and in Great Britain 1·89:1. Both of these ratios approximately allow of half-size increases in the gauge of wire used,

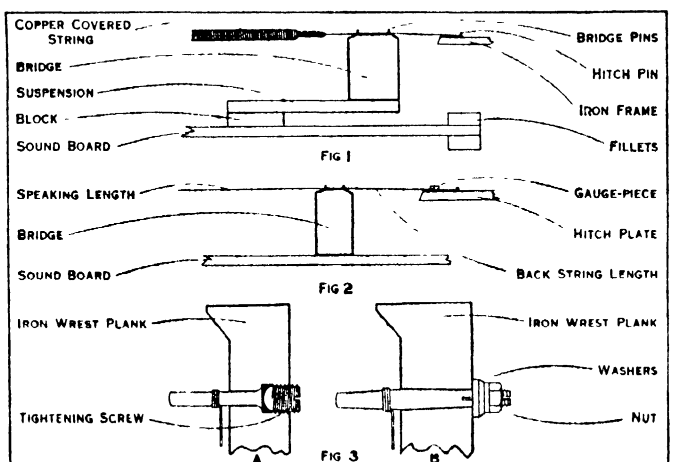

FIGS. 1, 2 & 3.—METHODS OF CONNECTING STRINGS TO SOUNDBOARD
1. Connecting of bass bridge to a sensitive part of the soundboard, 2. Slight dip of string after leaving bridge on its way to hitch-plate, 3. Two methods of avoiding the use of wooden-plank in extreme climates. (A) the screw pushes wrest-pin forward and holds it friction-tight, (B) the pin is held in a tapered hole by a nut

twice per octave, without departing far from the uniform tension initially decided upon. The English Music Wire Gauge advances one-thousandth of an inch in diameter per half size, while the New Westphalian Gauge advances 0·025 millimetre per half size, but there are irregularities in the English Gauge at various places, for reasons apparently unknown.

In small instruments, whether grands or uprights, it is impossible to carry theoretical string lengths throughout the piano, and compromises have to be made by shortening and thickening them in order to maintain the necessary high tension. Since short

and thick strings give a different and inferior tone quality it must not be expected that small instruments will give a pure and balanced "timbre" throughout the scale.

Cold drawn steel wire of the highest quality is specially made for the pianoforte industry, with a breaking strength of about 150 tons per square inch. Three types are now in favour, the polished, the plated and the rust-resisting. The last has been successfully developed, and is especially useful for export models.

Length of Strings.—In practice the strings of the 88th note are always between 5·0 and 5·5 centimetres in length, the shorter length being used for small instruments. From this starting point the succeeding lengths are calculated mathematically until it becomes necessary to employ heavier strings weighted by means of one or two layers of copper wire closely and tightly spun upon them. In order to gain in length and to fix the bridge to a sensitive part of the sound-board, well away from its edges, about fifty of the bass strings (12 singles and 19 bichords) are planned to cross over the others, reaching to a separate and higher bridge. This method of "overstringing" is now general in all but the cheapest pianos. The lengths of the copper-covered strings are not calculated mathematically but are made so that the lowest note is as long as possible. Additional length is often secured by means of a "suspended" bridge, as shown in fig. 1, which transmits the vibrations of the bridge to a point which should be at least six inches from the edge of the sound-board.

It has been found that a tension of about 160 lb. is advisable for the uncovered strings, and the diameter of wire is calculated from the formula $\frac{\sqrt{18,600\,T}}{nl}$, after which the nearest gauge to this diameter is selected, it being impracticable to manufacture a different diameter for each note. In the formula, "n" is the number of vibrations per second, "T" the tension in lb., and "l" the length of the vibrating portion of the string, in centimetres.

For the copper-covered strings some makers employ the formula $\frac{\sqrt{20,000\,T}}{nl}$, which gives the all-over diameter of the required string. Others calculate the weight per centimetre instead of the diameter, using the formula $\frac{111,250\,T}{n^2l^2}$, afterwards spinning strings of the required weight, as found by experimental determinations. For bichord bass strings a considerable increase of tension is provided, varying from 10 to 15%, and for the single bass strings a further increase of 15% and upwards, according to the size of the instrument.

The Sound-board.—As the strings vibrate they transmit pressure differences to the bridge attached to the sound-board (the bridge at the other end being as rigid as possible). The large area of the sound-board is thus set in motion, and this in turn agitates the air in its immediate vicinity, the aim being to provide a sensitive and extremely elastic board, capable of reproducing the most complicated wave-forms, with as little loss of energy as possible. In addition, the board must be made of material of low density and of uniform texture. The timber of the spruce family (*Picea excelsa*), where cut "on the quarter," answers all these requirements, the best qualities transmitting sound-waves along the grain at the rate of 16,000 feet per second and upwards. The transmission across the grain is about one-fourth of this speed, a difficulty which is surmounted by gluing bars of the same material across the back of the board at right angles to the grain. The Grotrian-Steinweg sound-boards are called "homogeneous," which means that the material selected has as far as possible the same closeness of grain all over its surface. This timber became known as "Swiss Pine," but is not botanically a pine. In America sound-boards are made of another timber of the same family, *Picea alba,* and a darker coloured wood of similar texture, *Abies pectinata,* is also used.

Most sound-boards are made with the grain running diagonally so that the long bridge runs almost parallel to the grain. The thickness is usually about $\frac{3}{8}''$ all over, some manufacturers insisting, however, that the treble end should be thicker. There is some theoretical evidence in favour of this, but in practice it is difficult to discover any difference. Sound-boards are always fitted so that they are slightly "bucked" or high in the middle, as though part of the surface of a sphere of about sixty feet radius. This shape is secured in several ways, perhaps the best being to subject the board to a dry temperature of 110 degrees Fahrenheit for some hours, and then to glue on the bars which have been planed to a slight curve. The subsequent expansion as the board takes up its usual ten per cent of moisture from the air produces the desired curvature. Since the board is always under pressure from the strings it follows that it behaves as an arch, which shape is retained through the rigidity of the rim to which it is fixed.

The "Down-bearing."—Good contact is maintained between strings and bridge by leaving the bridge a little higher than the general level of the two extremities. The resulting pressure of the strings on the sound-board is known as the "down-bearing," the regulation of which is one of the most critical processes in pianoforte manufacture. It is agreed that about one-fortieth of the tension is a suitable amount for each string to press upon the bridge. Translated into degrees this means that the bridge must stand high enough to allow the string to dip one and a half degrees after it passes over the bridge on its way to the hitch-pin on the iron frame. Allowance has to be made for the fact that as the tension is applied the whole board is pressed down somewhat, and the amount of such sinking depends upon its dimensions, barring and support round the edge. The extra height is not measured at the bridge, but by means of a straightedge laid across where the string will pass, the amount of clearance at the hitch-pin is allowed for. (*See* fig. 2.) It does not matter so much what the exact pressure is, but inequalities of pressure cause very serious results, affecting those strings which lie between places of excessive pressure, and robbing them of their adequate contact with the bridge. Good contact between strings and bridge is also maintained by means of bridge-pins which lie in the line of the strings and are inserted at an angle of 70 degrees with the plane of the bridge. By passing the string to the left of the front pin and to the right of the back pin a frictional grip is secured. This practice is almost universal, the only outstanding departure being Messrs. Broadwood's method of screwing studs to the bridge and passing the strings through these. Previous efforts to provide a studded bridge have been discarded owing to the studs working loose and causing falseness of tone, but Messrs. Broadwood claim to have overcome this difficulty.

Tone and Overtones.—Pianoforte tone is compound, each note consisting of a fundamental tone and its overtones, which, sounding together, form the "harmonic series," with their vibration rates in the ratio of 1:2:3:4, etc. For instance, the tone of "middle C" has for harmonics the following notes, the frequencies of which are inserted in brackets: C (261), C (522), G (783), C (1,024), E (1,305), G (1,566), B♭ (1,827), C (2,088), D (2,349) and so on. If these notes be played together as a chord it will be at once detected that the harmonics blend together pleasingly, with the exception of the seventh and ninth which are dissonant. By striking the strings at one-eighth of their length from the fixed end, it is believed that the best tone quality is produced, whether by discouraging the 7th and 9th harmonics or by encouraging the 4th is not yet scientifically proved. This strike proportion is used for all notes from the bass up to "pitch C," after which other considerations make it necessary to strike the string gradually nearer the end, the fraction at the extreme treble being empirically decided upon at about $\frac{1}{16}$. Since the discordant harmonics of these notes are very weak and even beyond the limits of human audition it does not matter if they are produced, the striking point being arranged to allow of a quicker recoil of the hammer from the string.

Toning the Hammers.—The process known as "toning" the hammers is an attempt to control the time of contact between hammer and string, a soft hammer staying long enough to damp out some of the partial tones, while a hard-nosed hammer accentuates them. If a string vibrates a thousand times per second, its "periodic time" is one-thousandth of a second, and experimental evidence proves that the best tone is emitted if the hammer is toned so that contact is maintained for about half this

period. English felt is used wherever the highest quality is required, its resiliency being second to none. Great pressure is used in modern hammer-making and the density at the treble end where the hammer dimensions are small, is more than double that of the bass hammers. The toner, by means of pricking the felt, lessens the hardness beneath the nose of the hammer, without disturbing it at the actual point of contact. In this he is entirely guided by his ear, the aim being to eliminate undesirable tone components and secure an evenly graded scale, with no audible break between the treble and bass strings.

The Action.—The hammers are actuated by a system of levers known as the "action," which is now made by firms specialising in this unit alone, rather than by the piano manufacturer himself. The noses of the hammers rest at a distance of two inches from the strings, but if a note is held down after having been played, the hammer is "checked" when it has rebounded five-eighths of an inch, so that the blow can be repeated rapidly. When the key is half-way down, the felt "damper" is lifted from the strings and remains lifted until the key is released

Pedals.—The tone is modified by means of two pedals, the left-hand pedal taking the hammers nearer to the strings and thus decreasing the force of the blow Sometimes the whole action is shifted to the right, so that the hammer only strikes two strings instead of three The right-hand pedal lifts all the dampers from the strings so as to sustain harmonies as long as required, and not merely for increased power. In America a central pedal is often added, called the "Sostenuto," which, instead of lifting all the dampers, affects only those which happen to be already lifted, keeping them so until the pedal is released Thus one is able to sustain a chord, leaving the hand free for other notes

The ideal point of contact for the dampers is at the same place as the striking point, and in grand pianos this is approximately arranged, the dampers lying along the strike line above the strings, and operated by gravity only In upright pianos a position just under the strike line is favoured, such actions being known as "under-damper," and the pressure obtained by springs The cheaper piano is sometimes provided with an older type wherein the damper is operated by gravity at a point just above the hammers This is known as the "over-damper" action, and although the vibrations of the strings are of less amplitude above the hammer-line than below it, a well-made over-damper action is still in favour by certain Continental makers of repute, owing to its more effective silencing of the harmonics

Touch.—The depth of touch for the keys has been standardised in all countries at 9 millimetres, with an additional millimetre to allow of the locking of the check and the free escapement of the "Jack" lever The pivoting of the key has to be so placed as to give the correct amount of lift at the other end, usually about 6 millimetres, but varying a little with the different makes of action The best "touch" is secured if the keys slope backwards a little when at rest, becoming exactly level when half depressed At this point begins the extra load due to the lifting of the dampers, but the momentum already gained is sufficient to render it unnoticeable A "touch weight" is used during the regulating of the action, so that when it is placed upon the end of the key, and suddenly released, the force exerted is just sufficient to make the note sound faintly. This "dead weight" of touch is not standardised, but averages 90 grammes in the bass, down to 60 grammes in the treble.

Frame.—The iron frame, which takes most of the load exerted by the pull of the 220 strings, is cast in one piece at the foundry, from an iron pattern which has been made 1 per cent larger than the finished frame, in order to allow for the contraction of the casting during cooling

Tuning Pins.—The tuning pins of mild steel, about 7 millimetres in diameter, are driven into a wrest-plank of quartered beech or maple, sometimes of ply construction to prevent splitting. The holes are bored slightly smaller than the pins, a ratio of 15:17 giving the correct amount of tightness. Since the plank is bolted to the iron frame and glued to the wooden back it follows that the load is shared between the frame and the back, the tendency in modern construction being to eliminate the wooden back altogether. The wrest-plank is often covered with a web of iron into which maple plugs have been driven, the tuning pins passing through these plugs into the plank. This method has proved very efficient and is being increasingly adopted in both upright and grand pianos. Patent methods of securing the tuning-pins have been introduced from time to time, but the method above described remains, and would seem likely to survive, being both efficient and free from complications

For tropical climates, an all-metal wrest-plank has proved its worth, the wrest-pins being held "friction tight" from the back of the plank Fig 3 shows an Australian and a German method of providing sufficient hold for the pin, at the same time allowing it to be adjusted finely by the tuner. In order to prevent the two surfaces from rusting together, a very fine grade of graphite is used as a lubricant The washers have a projection which fits into a slot running down the threaded portion of the pin, which ensures that they move with it during all adjustments.

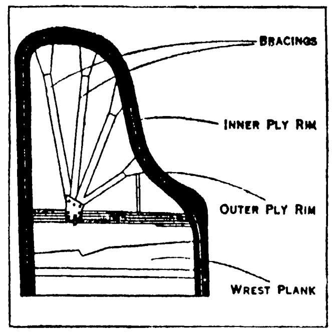

FIG 4—STEINWAY GRAND CASE-WORK, SHOWING PARTS

Standardisation.—The similarity in methods and design of the leading manufactures in all countries is accounted for by the necessity for standardisation of the keyboard, its height from the floor, the provision of room for the knees, the situation of the pedals, and the natural laws controlling the vibration of stretched strings In the upright piano the wooden back forms a convenient base to which the ends of the case are glued, besides being the means for securing rigidity for the edges of the sound-board and a support for both iron frame and wrest-plank

The peculiar form of the grand piano enables an immensely strong inner rim to be built up in one continuous bend, into which bracings are dove-tailed, and to which the key-bottom (supporting the key-board) is secured This inner rim, on which the sound-board and iron frame are fastened, may be six inches deep, and from $1\frac{1}{4}''$ to $1\frac{1}{2}''$ thick Additional rigidity is further provided by gluing this unit to an outer rim, also of ply formation, about a foot deep and from $1''$ to $1\frac{1}{4}''$ thick. The skeleton formation of the case-work of a large Steinway grand is shown in fig. 4, but it must be remembered that the lateral stiffness of such a structure varies inversely as the cube of its length, and therefore small grands do not need such elaborate re-inforcement, the very smallest (4 ft 3 in to 4 ft 6 in in length) often having no bracings at all. (S A. H)

PIANOLA: *see* PLAYER-PIANO

PIANOSA (anc *Planasia*), an island of Italy, belonging to the province of Leghorn, and forming part of the commune of Campo nele 'Elba, from which it is 11 m S W Pop. (1921) 908 As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq m The discovery of numerous fossilized bones of animals show that it was still united to the mainland in the quaternary period. Traces of human habitation in the neolithic period have been found. Augustus banished to it his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name It was depopulated in 1553 by the Turkish fleet, and only resettled in 1835.

PIARISTS, the popular name of a Catholic educational order, the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, founded by Joseph of Calasanza at Rome in the beginning of the 17th century Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth In 1622 the Congregation received a new constitution from Gregory XV., and had all the privileges of the mendicant

orders conferred upon it. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany and Austria.

Kniel in Wetzer und Welte's *Kirchenlexikon* (1895), vol. ix. and art. "Piarists" in the *Catholic Encyclopaedia.*

PIAROAN, an independent linguistic stock of South American Indians, named from the Piaroas, one of its most important tribes. The Piaroan tribes live in the region of the Venezuelan-Colombian border, along the Orinoco river between the Sipapo and the Matabeni, and on the course of the latter river, the Zama and lower Vichada. The Piaroas are described as a forest rather than a river people, using bark canoes constructed for temporary purposes only. Their houses are communal, and are circular and conical in shape, built of thatch. They are agricultural, using manioc as their main food and but little maize.

See J. Chaffanjon, *L'Orenoque et le Caura* (Paris, 1889); A. von Humboldt, *Personal Narrative of Travels to the Equinoctial Regions,* etc. (London, 1818).

PIASTRE, a monetary unit of Turkey, and also of Egypt, 100 piastres making one Turkish or Egyptian pound. The piastre itself is a silver coin containing 1·203 grammes of silver, 830 fine, in Turkey, and 1·4 grammes, 833 fine, in Egypt.

PIATRA (Neamtu), the capital of the department of Neamtu, Rumania, situated on the left bank of the river Bistrita, where it cuts a way through the Carpathian foothills. Pop. (1921) 26,000. A branch railway passes through the town, and at Bacau meets the main Czernowitz-Galatz line. The church of St. John's (or the Prince's) monastery was founded in 1497 by Stephen the Great. There are saw-mills and textile factories in Piatra, which has a considerable trade in wine and timber, and is also a popular summer resort. Neamtu is one of the most densely forested regions in Moldavia.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on Jan. 8, 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. In 1894 the fiftieth anniversary of his first appearance in London was celebrated by a reception given in honour of him and his lifelong friend Joachim. He retired from public life, owing to a severe illness, in 1897, and until his death at Bergamo on the 19th of July 1901 divided his time between his native town and Cadenabbia.

PIAUHY or **PIAUHI,** a north-eastern State of Brazil, bounded north and west by Maranhão, east by Ceará, Pernambuco and Bahia, and south by Bahia. It has a few miles of Atlantic coast-line on the north, and the Rio Parnahyba forms the boundary line with Maranhão throughout its entire length. Area, 94,795 sq.m.; pop. (1920) 609,003. Part of the State on the Atlantic coast and along the lower Parnahyba is low, swampy and malarial. South of this the country rises gradually to a high plateau with open *campos.* This plateau region is drained by numerous tributaries of the Parnahyba, chief of which are the Urussuhy, the Canindé and its tributary the Piauhy, the Gurgueia and its tributary the Parahim, which drains the large inland lake of Parnaguá, the Longa, and the Poty, which has its source in the State of Ceará. The Parnahyba is navigable for boats of 3 ft. draught up to Nova York, a few miles above the mouth of the Gurgueia. The climate is hot and humid in the lowlands and along the lower Parnahyba, but in the uplands it is dry with high sun temperatures and cool nights. The principal industry is stock-raising, which dates from the first settlement in 1674 by Domingos Affonso Mafrense, who established here a large number of cattle ranges. A secondary industry is the raising of goats. The agricultural products are cotton, sugar and tobacco. Much cotton is grown, and some of it manufactured. Forest products include rubber, carnauba wax and dye-woods. The exports include hides, skins, rubber, wax, tobacco and cotton. The capital is Therezina, on the right bank of the Parnahyba, 250 m. above Parnahyba (town), with which it is connected by a line of light-draught river boats. The town dates from 1852, is attractively situated, and is regularly laid out with broad, straight streets crossing each other at right angles. The population of the *Municipio* in 1920 was 57,500 which includes a large rural district. Other *municipios* with their populations in 1920, are Oeiras (24,563), founded in 1718 under the name of Moxa; Amarante (15,844); Valença (34,742); and Campo Maior (17,992).

PIAVE, a river in Italy, which played an important part in the latter period of the World War on the Italian front. It rises under the Paralba pass in the Carnic Alps and flows in a south-westerly direction past Belluno as far as Feltre and then turns to the south-east, flowing into the sea at Cortellazzo to the north-east of Venice, with another, older mouth nearer to Venice. Its course is 220 km. in length. Its depth and width vary very considerably according to the seasons of the year, a fact which had an important bearing on the operations along its banks. In its lower reaches its bed is a vast extent of gravel only filled in times of heavy rains or at the melting of the snows. After the Austro-German break-through at Caporetto in October 1917, the remains of the Italian II. army and all the III. fell back on the Piave between Pederobba and the sea and were reconstituted behind that river. The Austrians made repeated attempts to cross the river in the Nov. and Dec. battles, but were eventually driven back on to the left bank. For a time some British troops held a sector of the Piave front, but they were afterwards transferred to the Asiago plateau. On June 15, 1918 the Austrians delivered a general attack along the greater part of the Italian front, known as the battle of the Piave, their object being to break through into the rich agricultural area of the Veneto. They concentrated their attacks on the sector between Falzè di Piave and Nervesa (opposite the Montello hill, rising along the right bank), and on that between the Grave di Papadopoli, a gravel covered island in the river, and Musile. Two Austrian forces succeeded in getting across and occupied half of the Montello and some other points, but were forced by Italian counter-attacks to recross the Piave, after suffering heavy losses. Later an Italian local attack resulted in the conquest of the area between the old and the new Piave near the estuary. In Oct. 1918 an Italian offensive on a large scale was effected. The battle, which takes its name from Vittorio Veneto, east of the Piave, began on October 23, but did not extend to the Piave until the 27th. On that day a small mixed Italian force crossed the river near Valdobbiadene and a part of the X. army also crossed the Piave at the Grave di Papadopoli (this army, commanded by the earl of Cavan, comprised two British divisions). The bridges of the VIII. army were swept away by the current and the regiments which had got across were isolated, and as the British forces which had crossed were not strong enough to outflank the Austrians on the dominant position of San Salvatore, Gen. Caviglia, commander of the VIII. army, sent his XVIII. corps across on the British bridges; while that corps advanced up the river the British pushed east towards the Monticano; thus by the 29th the Austrian forces on the Piave were cut in half. On the 30th the bulk of the Italian attacking forces were across the river and the Austrians in full retreat.

PIAZZA ARMERINA, a city of Sicily, in the province of Caltanisetta, 43 m. W. of Catania; 2,360 ft. above sea-level. Pop. (1921) 27,479 (town), 38,406 (commune). It has a 16th-century cathedral, with a fine Norman campanile, and some of the houses and churches show Norman or Gothic architecture. The town was founded in the 12th century, and the inhabitants are of Lombard origin, and still speak a dialect of their own.

PIAZZI, GIUSEPPE (1746–1826), Italian astronomer, was born at Ponte, in the Valtellina, on July 16, 1746. He discovered, on Jan. 1, 1801, the first asteroid or minor planet, to which he gave the name of Ceres. He died at Naples on July 22, 1826.

See B. E. Maineri, *L'Astronomo Giuseppe Piazzi* (Milan, 1871); R. Wolf, *Biographien,* Bd. iv. p. 275; *Monatliche Correspondenz* (1810; portrait), xxi. 46; *Astr. Jahrbuch,* liv. 218; *Bulletin des sciences* (1826), vi. 339; *Edin. Journal of Science* (1827), vi. 193; *Memoirs Roy. Astr. Soc.* iii. 119; R. Grant, *Hist. Phys. Astronomy,* pp. 238, 510, 549.

PIBRAC, GUY DU FAUR, SEIGNEUR DE (1529–1584), French jurist and poet, was born at Toulouse. He studied law there with Jacques Cujas, and afterwards at Padua. In 1548 he

was admitted to the bar at Toulouse, and rose to be *juge-mage,* an office in Languedocian cities about equal to that of *prévôt.* He was selected in 1562 as one of the three representatives of the king of France at the council of Trent. In 1565 he became general advocate to the parlement of Paris, and extended the renaissance in jurisprudence which was transforming French justice. In 1573 he was sent by Charles IX. to accompany, as chancellor, his brother Henry (afterwards Henry III.) to Poland, of which Henry had been elected king. He was employed in negotiations with the so-called *politiques,* whom he managed to keep quiet for a while. In 1578 he became the chancellor of Marguerite of France, queen of Navarre. He died in 1584 He was the friend of Ronsard, de Thou and L'Hôpital, and left, among other literary remains, elegant and sententious *quatraines.*

PICA, the European representative of a group of diminutive rodent mammals, also known as tailless hares, mouse-hares, or piping hares, constituting the family *Ochotonidae* with the single genus *Ochotona.* From the more typical hares and rabbits they differ by the short and rounded ears, the absence of a tail, the shorter hind-limbs, and by complete collar-bones. The soles of the feet are hairy, and the fur is soft and thick. Picas are inhabitants of cold and desert regions. They dwell in the chinks between rocks, or in burrows, although one Himalayan species frequents pine-forests. They are very active, and most of the species utter a piping or whistling cry They store up a supply of grass for winter use. The Himalayan *roylei* may be seen in the daytime, but most kinds are nocturnal. The Siberian species, *O. alpina,* ranges into eastern Europe, but Central Asia is the headquarters, although a few species range into Arctic America and the Rocky Mountains. In size picas may be compared to guinea-pigs. There are several extinct genera.

See Rodentia, also J. L. Bouhote, "The Mouse-hares of the genus *Ochotona,*" *Proc Zool. Soc.* (London, 1905).

In printing pica is a type in size smaller than "English" and bigger than "Small pica." It is also known as 12 point The following passage is printed in pica:

Types are of various sizes, and the sizes are classified according to the dimensions of their "ems" or bodies.

"Pica" is the common standard of measurement in printing offices. The unit is a single letter of pica type called an "em."

PICARD, JEAN (1620–1682), French astronomer, was born on July 21, 1620, at La Flèche, Anjou. After acting as prior of Rillé, Anjou, for some years, he went to Paris and was admitted to the Academy of Sciences as an astronomer in 1666. In 1671 he went to examine Tycho Brahe's observatory, Uraniborg, in Denmark, and returned with some of the originals of Tycho's work Picard's measurement between Mahoisine and Amiens provided the first accurate measure of a degree of a meridian, and was used by Newton to verify his theory of gravitation. Picard founded *La Connaissance des Temps* in 1679, and edited it until his death on July 12, 1682.

His works are published in the 6th and 7th vols of the *Memoires* of the Academy of Sciences.

PICARD, LOUIS JOSEPH ERNEST (1821–1877), French politician, was born in Paris on Dec. 26, 1821, and joined the Parisian bar. In 1871 he accompanied Jules Favre to Versailles to arrange the capitulation of Paris, and in February he became minister of the interior in Thiers's cabinet. Attacked both by the Monarchist and the Republican press, he resigned in May. Later in the year he was sent as ambassador to Brussels On his return to Paris in 1873 he resumed his seat in the Left centre, and in 1875 became life senator. He died in Paris on May 13, 1877

PICARDY, an old province of France, bounded north by Hainaut and Artois, on the east by Champagne, on the south by the Île de France, and on the west by Normandy and the English channel. Its maritime frontier ran from the mouth of the Aa to the cliffs of Caux, and it included the whole of the basin of the Somme and part of that of the Oise. The chief towns of Picardy were Amiens, Boulogne, Abbeville, Laon, Soissons, Montreuil, Péronne, Beauvais, Montdidier, St. Quentin and Noyon. Its principal rivers were the Somme and the Oise. Picardy formed part of the archdiocese of Reims. Its bishoprics were Amiens, Beauvais, Senlis, Soissons, Noyon and Laon, and it contained the ancient abbeys of Corbie, St. Valéry and St. Riquier. In 1789 the province of Picardy was covered by the three bishoprics of Amiens, Noyon and Boulogne It was one of the provinces of the five great *fermes.* Its area now forms the department of the Somme and parts of the departments of Pas de Calais, Aisne and Oise.

The name of Picardy does not appear until the 13th century. At that time the province was divided into the two bailliages of Amiens and Vermandois, but its regular organization as part of the kingdom of France only dates from the beginning of the 16th century, when it was divided into north and south Picardy. North Picardy, or Picardy proper, formed one of the great military governorships of the kingdom, while south Picardy was included in the Île de France.

Under the Romans, Picardy was part of *Belgica secunda;* it was inhabited by the Morini, the Ambiani, the Veromandui, the Bellovaci and the Suessiones, whose names still appear in Amiens, Vermandois, Beauvais and Soissons. In the 5th century Picardy became the centre of Merovingian France Clovis had his first capital at Soissons; Charlemagne had his at Noyon, and Laon was the capital and the refuge of the later Carolingian sovereigns

During the later feudal period Picardy was the home of the counts of Vermandois, of Clermont and of Ponthieu, the sire of Coucy, and others The dukes of Burgundy were anxious to annex Picardy, in 1435, by the famous treaty of Arras, the royal towns and lands in the valley of the Somme were ceded by King Charles VII. to Burgundy. However, after the death of Charles the Bold in 1477 Picardy was finally united with the crown of France. The province was early an industrial district. Flemish immigrants brought with them the lucrative trade of weaving cloth, and the Somme towns were soon competing with those of Flanders. The Picard towns were noted for their love of independence, which often brought them into collision with the kings of France during the 13th century. At a later time the province received a number of Spanish immigrants. In the middle ages the Picards formed one of the four "nations" recognized in the organization of the University of Paris.

See A Labourt, *Essai sur l'origine des villes de Picardie* (Amiens 1840), P. N Grenier, *Introduction à l'histoire générale de la province de Picardie* (Amiens, 1856), and H. Carnoy, *Littérature orale de la Picardie* (1883).

PICARESQUE NOVEL, THE. This special form of the *roman d'aventures* may be defined as the prose autobiography of a real or fictitious personage who describes his experiences as a social parasite, and who satirizes the society which he has exploited The picaroon, or rogue type, is represented by Encolpios Ascyltos and Giton in the *Satyricon,* which tradition ascribes to Petronius; it persists in Lucian, in the *Roman de Renart,* in the *fabliaux* and in other works popular during the middle ages But in its final form the picaresque novel may be regarded as a Spanish invention The word *picaro* is first used, apparently, in a letter written by Eugenio de Salazar at Toledo on April 15, 1560; the etymology which derives *picaro* from *picar* (to pick up) is unsatisfactory to philologists, but it suggests the picaroon's chief business in life. A connection with French *picoreur* (*praedator*) is possible The earliest application of the expression *picaro* to a character in fiction occurs in Mateo Alemán's *Guzmán de Alfarache* (1599) But a genuine *novela picaresca* existed in Spain before the word *picaro* became generally current

Spanish Examples.—The earliest specimen of the kind is *La Vida de Lazarillo de Tormes y de sus fortunas y adversidades* an anonymous tale long attributed, on insufficient grounds, to Diego Hurtado de Mendoza (*q v*) The authorship of this brilliant book and the circumstances of its publication are obscure however, it was certainly issued not later than 1554 (in three editions), and was thrice reprinted before 1559, when it was placed on the Index. Imitations of so successful a story were inevitable, and as early as 1555 there appeared at Antwerp *La segunda parte de Lazarillo de Tormes,* an anonymous seque

which completely misinterpreted the irreverent wit of the original. The first part had been prohibited because of its attacks on the clergy; in the second part the hero is presented as a devout youth transformed into a tunny. Another sequel, by Juan de Luna, was published at Paris in 1620. Meanwhile, many surreptitious copies of the first part were introduced into Spain; the Inquisition finally gave up the attempt to suppress it, and in 1573 an expurgated edition was authorized. In 1599 Mateo Alemán (*q.v.*) published the *Primera parte de Guzmán de Alfarache.* It is modelled upon *Lazarillo de Tormes,* being the autobiography of the son of a ruined Genoese money-lender; but the writer indulges in a tedious series of moralizings This contrasts sharply with the laconic cynicism of *Lazarillo de Tormes;* but *Guzmán de Alfarache* is richer in invention, in variety of episode and in the presentation of character Its extraordinary popularity tempted a Valencian lawyer named Juan José Martí to publish a *Segunda parte de la vida del pícaro Guzmán de Alfarache* (1602) under the pseudonym of Mateo Luján de Sayavedra; but in 1604 Alemán brought out the true continuation A third part, written in Spanish by the Portuguese Felix Machado de Silva, Marques de Montebilo, was first printed in 1927. The *Viaje entretenido* (1603) of Agustín de Rojas is a realistic account of the writer's experiences as a strolling actor and playwright, and, apart from its considerable literary merits, it is an invaluable contribution to the history of the Spanish stage as well as a graphic record of contemporary low life.

The next in chronological order of the Spanish picaresque tales is *La Pícara Justina* (1605), the history of a woman picaroon, which it has long been customary to ascribe to Andrés Pérez, a Dominican monk; there is, however, no good reason to suppose that the name of Francisco López de Ubeda on the title-page is a pseudonym. The *Pícara Justina* has wrongly acquired a reputation for indecency; its real defects are an affected diction and a want of originality. The *Pícara Justina* is now read solely by philologists in quest of verbal eccentricities. Gines de Pasamonte, one of the secondary figures in *Don Quixote* (1605–15), is a singularly vivid sketch of the Spanish rogue, and in the comedy entitled *Pedro de Urdemalas* Cervantes again presents a brilliant panorama of picaresque existence He returns to the subject in *Rinconete y Cortadillo* and in the *Coloquio de los perros,* two of the best stories in the *Novelas ejemplares* (1613). In the *Viaje del mundo* (1614) the zealous missionary Pedro de Cevallos interpolates amusing tales of what befell him in the slums of Andalusia before he fled from justice to America In *El Pasajero* (1617) Cristóbal Suárez de Figueroa fills in the sketch of the knavish innkeeper already outlined by Cervantes in *Don Quixote* Evidence of the widely diffused taste for picaresque literature is found in *Enríquez de Castro* (1617), a story in Spanish by the Frenchman François Loubayssin de Lamarca

The roving instinct of Vicente Martínez Espinel (*q v*) had led him into strange and dangerous company before and after his ordination as a priest, and his *Relaciones de la vida del escudero Marcos de Obregón* (1618) is remarkable for a baffling compound of fact with fiction written in the lucid style of which Espinel was a master; it was largely utilized by Le Sage in *Gil Blas.* Within five months of its publication at Madrid a fragmentary French version by the Sieur d'Audiguier was issued at Paris, and at Paris also there appeared a Spanish picaresque story entitled *La desordenada codicia de los bienes ajenos* (1619), ascribed conjecturally to a certain Dr. Carlos García, who reports his conversation with a garrulous gaol-bird, and appends a glossary of slang terms used by the confraternity of thieves Every kind of picaroon is portrayed with intelligent sympathy by Alonso Jerónimo de Salas Barbadillo, who is always described as a picaresque novelist; yet he so constantly neglects the recognized conventions of the Spanish school that his right to the title is disputable. Thus in *La Hija de Celestina* (1612) he abandons the autobiographical form, in *El subtil cordobés Pedro de Urdemalas* (1620) he alternates between dialogue and verse, and in *El Necio bien afortunado* (1621) the chief character is rather a cunning dolt than a successful scoundrel. The pretence of warning newcomers against the innumerable occasions of sin in the capital is solemnly kept up by Antonio Liñan y Verdugo in his *Guía y avisos de forasteros que vienen a la corte* (1620), but in most of his tales there is more entertainment than decorum.

An unusual gravity of intention is visible in Jerónimo de Alcalá Yañez y Ribera's *Alonso, mozo de muchos amos* (1624–26), in which the repentant *pícaro* Alonso, now a lay brother, tells the story of his past life to the superior of the monastery in which he has taken refuge.

At about this time there lived in Spain an ex-nun named Catalina de Erauso, who fled from her convent, dressed herself in men's clothes, enlisted, was promoted ensign and saw more of life than any other nun in history. Her adventures arrested the attention of De Quincey, who would seem to have read them in a Spanish original which has been admirably translated since then by the French poet José Maria de Heredia. The Spanish original, in its existing form, was issued no earlier than 1829 by Joaquín María de Ferrer, whose character is not a satisfactory guarantee of the work's authenticity, but its interest is unquestionable. No such suspicion attaches to the *Vida* of Alonso de Contreras, first published in 1899, in which every convention of the picaresque novel is faithfully observed, and the incidents are no doubt substantially true, though this ex-captain, like most converts, judges his own past with unnecessary harshness This subtle form of vanity also pervades the *Comentarios de el desengañado de sí mismo* of Diego Duque de Estrada, a rakish soldier and inferior dramatist whose autobiography (begun in 1614 and continued at intervals during many years) was not printed till 1860. A far higher order of talent distinguishes the *Capitulaciones de la vida de la corte y oficios entretenidos en ella,* a bitterly unsparing review of picaresque life written by the great satirist Francisco Gómez de Quevedo y Villegas (*q v*). These thumbnail sketches were the preparatory studies worked up into the more elaborate *Vida del buscón Don Pablos* (1626), the cleverest and most revolting book of its class

The *Varia fortuna del soldado Píndaro* (1626) added nothing to the established reputation of Gonzalo de Céspedes y Meneses Alonso de Castillo Solórzano (*q v*) tempted the public with three picaresque stories published in quick succession: *La Niña de los embustes, Teresa de Manzanares* (1634), the *Aventuras del Bachiller Trapaza* (1637) and a sequel to the latter entitled *La Garduña de Sevilla* (1642). But the style was no longer welcomed with the old enthusiasm in Spain The *Bachiller Trapaza* was destined to be continued by Mateo da Silva Cabral in Portugal and to be exploited by Le Sage who likewise utilized in *Gil Blas* episodes taken from *El Siglo pitagórico* (1644), the work of Antonio Enríquez Gómez (*q v*). The primitive rogue returns to the scene in *La Vida y hechos de Estebanillo González* (1646) Le Sage drew upon him in the *Histoire d'Estevanille González.*

Outside Spain.—Meanwhile, the rogue had forced his way into other European literatures. The Antwerp continuation (1555) of *Lazarillo de Tormes* brought the original to the notice of northern readers, and this first part was translated into French by Jean Saugrain in 1560, a new edition being called for in the following year. A Dutch version was issued anonymously in 1579, and it seems extremely likely that the book had been translated into English before this date.

The first known edition of David Rowland's version of *Lazarillo de Tormes* is dated 1586, but as a licence to print a translation of this tale was granted on July 22, 1568–69, it is probable that a 1576 edition which appears in the Harleian catalogue really existed. Numerous reprints (1599, 1639, 1669–70, 1672, 1677) go to prove that *Lazarillo de Tormes* was very popular, and that Shakespeare had read it seems to follow from an allusion in *Much Ado about Nothing* (Act. II, sc. i.): "Now you strike like the blind man; 'twas the boy that stole your meat, and you will beat the post." To Thomas Nash belongs the credit, such as it is, of being the first to write a picaresque novel in English: *The Unfortunate Traveller; or the Life of Jack Wilton* (1594). Nash led the way, and a reference to "Spanish pickaroes" in Middleton's *Spanish Gipsie* indicates that the picaroon type had speedily become familiar enough for London playgoers to understand the reference. Interest in picaresque literature was kept alive in

England by James Mabbe's admirable version (1622) of *Guzmán de Alfarache;* by *The Son of the Rogue or the Politic Thief* (1638), an anonymous translation, done through the French, of *La desordenada codicia;* and by another anonymous translation (1657), likewise done through the French, of Quevedo's *Buscón.* The result of this campaign was *The English Rogue described in the Life of Meriton Latroon, a witty Extravagant* (1665), by Richard Head and Francis Kirkman.

It is not till Defoe's time that the English picaresque novel acquires any real importance. There is a female picaroon in *Moll Flanders,* and, as Defoe read Spanish, it is conceivable that Moll Flanders was suggested by the *Pícara Justina;* but this resemblance does not make a picaresque novel of *Moll Flanders.* The satirical spirit which is lacking in *Moll Flanders* is abundantly present in *Colonel Jack,* which bravely aims at exhibiting "vice and all kinds of wickedness attended with misery." Henceforward the picaroon is naturalized in English literature, and is gloriously reincarnated in Fielding's *Jonathan Wild* and in Smollett's *Ferdinand, Count Fathom.*

The Dutch translation of *Lazarillo de Tormes* (1579) did not enable the picaresque novel to strike root in Holland, yet from it is derived one of the best Dutch comedies, *De Spaensche Brabander Jerolimo* (1616) of Gerbrand Bredero. A German translation of *Guzmán de Alfarache* was published by Aegidius Albertinus in 1615; both *Lazarillo* and *Rinconete y Cortadillo* were translated by Niclas Ulenhart in 1716, and in 1627 there appeared an anonymous version of the *Pícara Justina* The Spanish tradition was followed by Martin Frewden in a continuation (1626) of *Guzmán de Alfarache,* but the only original picaresque novel of real value in German is Grimmelhausen's *Simplicissimus.* The attempt to acclimatize the picaresque novel in Italy failed completely.

The first translation of the *Novelas ejemplares* was published at Paris in 1618 by Rosset and d'Audiguier; and French translations of *Guzmán de Alfarache,* of *Marcos de Obregón,* of *La Desordenada codicia,* of the *Buscón* and of the *Pícara Justina* were printed in 1600, 1618, 1621, 1633 and 1635 respectively. Scarron frankly mentions Castillo Solórzano's *Garduña de Sevilla* in the *Roman Comique* (1651), and his *Précaution inutile* and *Les Hypocrites* are convincing proofs of close study of Spanish picaresque stories. the *Précaution inutile* is taken from *Guzmán de Alfarache,* and *Les Hypocrites* is merely a translation of Salas Barbadillo's *Hija de Celestina.* The *Roman bourgeois* (1666) of Antoine Furetière is generally described as a picaresque novel, but it is concerned with the foibles of the middle class rather than with the sly devices of common vagabonds.

The Spanish picaroon lives again in *Gil Blas,* where, with a dexterity almost rarer than original genius, a master of literary manipulation fuses materials unearthed from forgotten and seemingly worthless Spanish quarries. Gil Blas is a creation of the gentler, sunnier French spirit, like Beaumarchais's Figaro he is a Spaniard born, reared and humanized in Paris, and these two are the only picaroons whose relative refinement has not been gained at the cost of verisimilitude. But the old original scoundrel was not yet extinct. in the interval between the appearance of the *Barbier de Séville* and the *Mariage de Figaro* Restif de la Bretonne produced a sequel (1776) to the *Buscón*—a sequel so dull as to be wellnigh unreadable. The untamed Spanish rogue had become impossible towards the end of the 18th century: in the 19th he was deliberately rejected when Théophile Gautier wrote his *Capitaine Fracasse.* Yet Gautier conscientiously provides a Spanish atmosphere. *Capitaine Fracasse* is the last important book which continues the picaresque tradition But picaresque fiction can never be exhausted while human nature is unchanged. Pereda (*q.v.*) in *Pedro Sánchez* (1884) touches the old theme with the accent of modernity; and the *pícaro* flourishes afresh in the novels of Baroja.

PICASSO, PABLO (1881–). The initiator of Cubism in modern painting He was born on Oct. 23, 1881, at Malaga, in Spain. His father was an artist and professor at the Academy at Barcelona, and under him Pablo received his first lessons in art. After many visits to Paris, he settled there in 1903 Though a Catalan by birth, he developed his art in France, where he became one of the leaders of the Post-Impressionist school

His early work displays a clear contour, a carefully planned space arrangement, and plastic modelling in cool, greenish-grey tones, almost monochrome One might trace therein the influence of Daumier and of Toulouse-Lautrec Like the latter, he chose the subject matter of his pictures from the life of the circus, and from the morbid side of life in a big city, and he rendered with intense sincerity of feeling the strained and sad look of young soubrettes of Montmartre, of acrobats and harlequins He thus, from the beginning, followed a line distinct from that of Matisse and his Fauvist following, who took pleasure in colour and flat patterns, as such, and who never entirely broke with the traditions of Impressionism. To this early period are. "La Famille Soler" (1903), a rhythmically composed family group; "l'Aveugle" (1903), archaic in the delineation of form; "La Boule" (1905), a composition with two acrobats

The Cubistic formula was gradually evolved by Picasso and Georges Braque, between 1906 and 1910, while studying the composition of still life groups consisting mainly of bowls with fruit, bottles, glasses, and musical instruments It was Braque who first introduced into his designs nails and bits of printed paper, delighting in the harmonious distribution of certain black letterpress on white paper Picasso then added pieces of wood and other tangible objects, which led to a form of art where sculpture and painting were combined.

During Picasso's earlier Cubist period, the surfaces of his canvases were delicately toned in brown or grey by dots in pointillist fashion displaying some constructive design—mainly abstract, though here and there realistic fragments of recognizable objects were introduced. The gradations of light and dark suggested shading and space. At a later period this three dimensional element disappeared; colour notes were introduced and the design formed a purely two dimensional pattern

The artist did not seek to imitate form, but to create form As opposed to the Impressionist pre-occupation with the rendering of ever-changing and superficial appearances, he wished to make images, which, by the clearness of their structure, should convey an idea of life and reality Carrying his convictions to the logical extreme, he discarded all resemblance to natural form, and endeavoured to create a purely abstract language of form—a visual music Thus, though these pictures may seem to most of us theoretic abstractions, the artist tried to convey a deep reality. "For reality alone, even when concealed has power to arouse emotion." In these realistic and mystical conceptions he shows himself a true son of Spain

After 1918, Picasso again based his pictures on natural form His paintings became magnificently plastic and monumental His clear, incisive outline drawings are executed with forcible directness and with rigid economy of means

Picasso's inventive gift, which led him from one experiment to another, inspired many followers. Painters such as Metzinger, Gleizes, Leger, Villon, and sculptors such as Archipenko and Lipschitz, to name only a few, followed in his wake. He was one of the first to appreciate the weird expressiveness of negro sculpture; his style led to an appreciation of "significant form" and of con-

structive design in all branches of art. He became the paramount influence in modern art, besides Cézanne, who is sometimes claimed as the initiator of the Cubist movement; though the great artist of Aix, with his intense feeling for nature, would probably have disowned this offspring.

Picasso's influence was also felt on the stage. He himself produced a series of designs for curtains, scenery and costumes for certain Russian ballets. The history of his collaboration with Jean Cocteau and Erik Satie in the ballet *Parade* (1917) is told by Cocteau in *Le coq et L'Arlequin* (English trans. 1921). Other ballets for which he produced designs were *Tricorne* (1920), *Cuadro Flamenco*, an Andalusian dance (1921), and *Pulcinella* (1926). In the creation of these artistic ensembles his great qualities as a designer, the unlooked for beauty of his harmonies, his astonishing audacities, stand him in good stead.

The most representative collection of his later work is in the possession of G. F. Reber, Lausanne. The best early works are with Lotte von Mendelssohn Bartholdy in Berlin. Other important works are with Paul Rosenberg, Paris; A. Flechtheim, Düsseldorf, and with the Barnes Foundation, Philadelphia.

Picasso illustrated several books, notably André Salmon, *Le Manuscrit trouvé dans un chapeau*. He executed portrait drawings of contemporary writers and musicians such as Stravinsky, J. Cocteau, M. Jacob, Apollinaire, A. Salmon, etc. He also etched several plates.

See Guillaume Apollinaire, *Les Peintres Cubistes* (1912); Max Raphael, *Von Monet zu Picasso* (Munich, 1922); Leone Rosenberg, *Cubisme et Tradition* (1920); Maurice Raynal, *Picasso* (1921); André Salmon, *L'Art Vivant* and *Picasso* (1920). (I. A. R.)

PICAYUNE, the name in Florida and Louisiana of the Spanish half-real = $\frac{1}{16}$ of a dollar, $6\frac{1}{4}$ cents, and hence used of the United States 5 cent piece; from the French *picaillon*, an old copper coin of Piedmont, and possibly related to the Italian *piccolo*, little, small. In America the word is used of anything trifling or contemptible.

PICCININO, NICCOLO (1386–1444), Italian *condottiere*, born at Perugia. He served under the Visconti of Milan in campaigns against Francesco Sforza from 1425 to 1444.

PICCINNI, NICCOLA (1728–1800), Italian composer, was born at Bari, Naples, on Jan. 16, 1728. He was educated under Leo and Durante, at the Conservatorio di Sant' Onofrio in Naples. His first opera, *Le Donne dispettose*, was produced in 1755, and in 1760 he composed, at Rome, *La Cecchina, ossia la buona Figliuola*, an *opera buffa* which attained a European success. It was followed by many others, one of which, also an opera buffa, *Il Viaggiatori* (Naples 1774), had nearly as great a success as *La Cecchina*. In 1776 Marie Antoinette invited him to Paris. He had married in 1756 his pupil Vincenza Sibilla, a singer, whom he never allowed after her marriage to appear on the stage. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him, apparently against his will, to Gluck, by persuading the two composers to treat the same subject—*Iphigénie en Tauride*—simultaneously. The Parisian public now divided itself into two rival parties, which, under the names of Gluckists and Piccinnists, carried on an unworthy and disgraceful war. Gluck's *Iphigénie* was first produced on May 18, 1779. Piccinni's *Iphigénie* followed on Jan. 23, 1781, and, though performed seventeen times, was soon forgotten. Of the works of Piccinni's Paris period the best is *Didon* (1783), which kept the stage for half a century. In 1789, after the outbreak of the French Revolution, Piccinni returned to Naples, where he was at first well received by King Ferdinand IV.; but the marriage of his daughter to a French democrat brought him into irretrievable disgrace. For nine years after this he maintained a precarious existence in Venice, Naples and Rome; but he returned in 1798 to Paris, where a small place was found for him at the Conservatoire. He died at Passy, Paris, on May 7, 1800.

See P. L. Ginguené, *Notice sur la vie et les ouvrages de Niccola Piccinni* (Paris, 1801); E. Demoiresterres, *La Musique française au 18e siècle, Gluck et Piccinni, 1774–1800* (Paris, 1872); E. Blom, *Stepchildren of Music* (1926). For a list of his operas, which number over 80, see *Rivista musicale italiana*, viii. 75.

PICCOLO, a small flute of less than half the dimensions of the large concert flute and pitched an octave higher. The principles of construction and the acoustic properties are the same for the piccolo as for the flute, with the exception that the piccolo does not contain the additional tail-piece with the extra low keys, which give the flute its extended compass.

PICCOLOMINI, the name of an Italian noble family, prominent in Siena (*q.v.*) from the beginning of the 13th century onwards. In 1220 Enghelberto d'Ugo Piccolomini received the fief of Montertari in Val d'Orcia from the emperor Frederick II. as a reward for services rendered. They obtained great wealth through trade, and established counting-houses in Genoa, Venice, Aquileia, Trieste and in various cities of France and Germany. Supporters of the Guelph cause in the civil broils by which Siena was torn, they were driven from the city in the time of Manfred, restored after the Angevin victories, expelled again during the brief reign of Conradin and again restored with the help of Charles of Anjou. Their commercial influence passed to the Florentines. Many members of the house were distinguished ecclesiastics, generals and statesmen in Siena and elsewhere; two of them were popes, viz., Aeneas Silvius Piccolomini (Pius II., *q.v.*) and Francesco Piccolomini (Pius III., *q.v.*).

See Richter, *Die Piccolomini* (Berlin, 1874); A. Lisini and A. Liberati, *Albero della famiglia Piccolomini* (Siena, 1899); and articles by A. Lisini in the *Miscellanea storica senese*, 3rd series 12, and 4th series, 17 and 189.

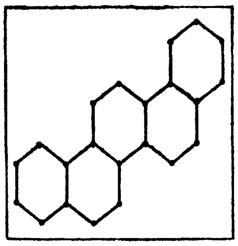
PICCOLOMINI, OCTAVIO, Prince (1599–1656), duke of Amalfi, Austrian general, was born on Nov. 11, 1599 in Florence, and carried a pike in the Spanish service at the age of sixteen. On the outbreak of the Thirty Years' War he served in Bohemia and Hungary, then in Spain and Italy. In 1627 he reentered the Imperial service as colonel and captain of Wallenstein's lifeguard. He was disgraced for practising extortion at Stargard in Pomerania, but his adroitness soon secured him the rank of "colonel of horse and foot." In the Mantuan War Piccolomini acted both as subtle diplomatist and as plundering soldier of fortune when Gustavus Adolphus invaded Germany.

Piccolomini was interned at Ferrara as a hostage for the ratification of a treaty, but joined in urging Wallenstein's reappointment as commander-in-chief. He was not immediately promoted on the duke's reappearance, and served under General Holk, an officer brought in from the Danish service, in the preliminary operations and in the battle of Lützen. After Lützen, the Emperor made Piccolomini a *general-feldwachtmeister*. At the same time, however, Holk was created a field marshal at Wallenstein's instance, much to his rival's chagrin. In 1633 Piccolomini commanded an important detachment posted at Königgrätz to bar the enemy's advance from Silesia into Bohemia. In May he accompanied Wallenstein on his advance into Silesia, but disapproving of the duke's policy, joined in a military conspiracy, which ended in the murder of Wallenstein (Feb. 29, 1634). Piccolomini's own part in the tragedy is commemorated in Schiller's *Wallenstein*. His material rewards for his activities in connection with the downfall of Wallenstein were his marshal's bâton, 100,000 gulden and the beautiful estate of Nachod in the Riesengebirge.

In 1638 Piccolomini was made a count of the empire, and in 1639, won a great victory over the French (relief of Thionville, July 7, 1639), was rewarded with the office of privy councillor from the emperor and with the dukedom of Amalfi from the king of Spain. But instead of being appointed, as he hoped, Gallas's successor, he was called in to act as *ad latus* to the Archduke Leopold Wilhelm, with whom he was defeated in the second battle of Breitenfeld in 1642. After this he spent some years in the Spanish service, being granted the title of grandee and the order of the Golden Fleece. Having re-entered the Imperial army, he was again disappointed of the chief command by the selection of the brave veteran Peter Melander, Count Holzapfel; but in 1648 he was at last appointed lieutenant-general of the emperor, and thus conducted as generalissimo the final campaign of the Thirty Years' War at the end of which he was made prince. He died on Aug. 11, 1656. He left no children (his only son Josef Silvio, the "Max" of Schiller's *Wallenstein*, was murdered

by the Swedes after the battle of Jankau in 1645), and his titles and estates passed to his brother's son.

PICENE, $C_{22}H_{14}$, an aromatic hydrocarbon found in the products of the destructive distillation of lignite and peat tars and in the residues from the rectification of Californian petroleum. Picene crystallises in colourless leaflets with a blue fluorescence; it melts at 364° C and boils above 500° C. A study of its oxidation by E. Bamberger and F. D. Chattaway (1893) gave picene-quinone (an *ortho*-diketone) and picenic acid. The latter when distilled with lime yielded ββ-dinaphthyl. These facts support the above constitutional formula, $C_{22}H_{14}$.



MOLECULAR ARCHITECTURE OF PICENE (CLOSED RING)

BIBLIOGRAPHY.—A. E. Everest, *The Higher Coal Tar Hydrocarbons* (1927).

PICENES. The Picenes do not figure at all prominently in the writings of ancient historians. They played a considerable rôle, however, in the confederacy of Italian states which challenged the hegemony of the growing Roman republic, and were punished at the end of the Social War by the complete suppression of their independence. The Picene capital was Ascoli, a little south of Ancona, on the eastern foothills of the Abruzzi.

The territory of the Picenes extended, to judge from the uniform character of the archaeological remains, all along the Adriatic coast from Rimini to the river Sangro; south of which again the Samnite mountaineers of Aufidena exhibited a civilization of identical character, though far less opulent. Inland, the Picene influence, and very probably the same population, extended as far as the midrib of the Apennines. A very ancient settlement at Terni, made long before 1000 B.C., may plausibly be attributed to them, and some writers think that they had a certain number of stations even in Latium. This would be perfectly natural if the Picenes were the principal survivors of a fairly homogeneous Neolithic population which once extended over the whole north and centre of Italy. According to this theory the Neolithic people were conquered and overwhelmed first by the invaders of the Bronze Age and then by the Villanovans (*see* VILLANOVANS). Neither of these incursions, however, penetrated further down the east coast than Rimini, at which point they were checked and diverted by the fighting forces of the Picenes.

This people retained its independence down to the third century B.C. when it finally succumbed to the Romans. It represents a phase of culture in the Early Iron Age diametrically opposed to that of the Villanovans, derived from a different source and developed under different inspiration. The first contrast between Villanovans and Picenes is in respect of their burial customs. The Villanovans cremated their dead, and the small percentage of inhumations occurring here and there within their territory may be ascribed to the survival of some few of the original Neolithic inhabitants. The Picenes on the other hand used no rite except inhumation; they buried their dead in the earth, generally in the contracted position customary among the aborigines, and cremation was entirely unknown in their part of the country.

The beginning of archaeological research in Picenum dates from the discovery by E. Brizio, in 1892, of two large and important cemeteries at Novilara, near Pesaro. Two remarkable stelae had been found in this neighbourhood 30 years earlier, with lines written in a script resembling the Etruscan in it's general character, but expressing a wholly different language which is inferred to be Sabellic (*q.v.*). Several more of these stelae were found at Novilara itself, and at neighbouring places including Fano, but they still await translation. Two of them are engraved with rude but very interesting pictures of native life, representing naval battles and scenes of hunting and fighting. They are further ornamented with spiral designs, which misled earlier investigators, who saw only their superficial resemblance to sub-Mycenaean patterns. It is now established that the stelae are at any rate not older than 700 B.C.

In the Novilara cemeteries were found, besides stelae, numerous other objects and ornaments which make it possible to reconstruct some outlines of the economic history of the Adriatic coast. About a dozen tombs at Novilara are as early as the 10th and 9th centuries B.C., while a few sporadic finds at Ancona and neighbouring points are no less ancient. From the contents of these it can be seen that the east coast of Italy was participating as early as the 10th century in the important trade in Baltic amber, which came down a main trunk route to the head of the Gulf of Venice. It can be seen also that Pesaro and Ancona were in no way dependent upon Bologna, inasmuch as many of the fibulae are of types quite unknown to the Villanovans though perfectly familiar in Greece and Sicily.

It is to commercial relations, rather than to any movement of immigration, that the composite character of Picene civilization should be attributed. In spite of the numerous details of their life which suggest analogies with the Balkans, or with Greece of the Dipylon period, there is no evidence that the population was derived, or substantially recruited, from either of these sources. The general stock of the inhabitants remained as it always had been, predominantly composed of the Mediterranean race originally derived from North Africa.

The essential characteristic of the Picenes is that they were primarily and above everything else fighting men. It has been pointed out that even before the dawn of the Iron Age they were obliged to defend their borders. They succeeded in maintaining their independence for many centuries. It is not surprising, therefore, that many tombs at Novilara contained weapons. The favourite arm was the spear, and the next in frequency was the dagger, of which there were several patterns. Swords seem to have been rather the weapons of the élite, and were extremely handsome. Helmets are fairly frequent, shields very rare, in the graves.

From graves of the 8th and 7th centuries B.C. at Novilara a complete picture may be recovered of the arms and equipment of a Picene foot soldier. His favourite sword was a broad and short weapon of iron, intended, like a sabre or a tulwar, for the heaviest cutting. Its edge was on the inside, and the hilt curved back at an angle like that of an ancient Bosnian hewing-knife. In fact there can be no doubt that swords of this kind were originally imported from the Balkans where the general type has always been well known. The curiously shaped sheath was made of wood, covered with sheets of bronze finely engraved with geometric patterns. Other swords found at Novilara are definitely Greek in origin, being of shapes familiar from the paintings on Dipylon vases. Similarly the helmets and shields are of Greek patterns, but the daggers, except when they seem to be original Italian products, follow the stock forms derived from the Hallstatt series prevalent all over Europe. The entire outfit is thus curiously hybrid in character, and quite unlike that of any other Italians. Not less characteristic than the armament of the men were the ornaments and apparel of the women. A certain number of objects were imported from the factories of Etruria or Bologna. Such are the bronze manicuring sets hung upon chatelaines attached to the waist, and the bronze ear-cleaners terminating in the figure of a monkey or of Aphrodite surrounded by doves. But the narrow girdles made of chain mail in links, the huge and elaborate pendants terminating in imitation sea-shells, the handsome torques and pectorals make an ensemble quite unlike anything found among Villanovans or Etruscans.

The rich cemeteries discovered along the coast in the neighbourhood of Ancona have been little studied, and no full publication of them is yet available. All the material obtained from them may be seen in the Ancona museum, in the large buildings of a disused monastery in the city. The richest cemetery was that of Belmonte, but the collections from Cupra-marittima, Grottamare and several smaller sites are also very important. Belmonte, in particular, which dates to the 6th and 5th centuries B.C., has yielded some very fine examples of Ionic Greek work in the minor arts. There are bronze bowls decorated with figurines of cast bronze, a favourite representation being that of Herakles as the tamer of lions and horses; jugs and vessels of hammered bronze and many superb carvings in amber, of which there was a prodigal abundance at this period. At Rapagnano were found two

shield-bosses of bronze, ornamented with scenes of combat between mounted men and foot soldiers in the best Ionic style. Greek influence was entirely predominant in Picene art from the 6th century onwards, but it is important to observe that it found its way, not through Etruria, but quite directly from the Greek colonies of southern Italy. This is proved by the simultaneous presence in these tombs of the very distinctive and peculiar Apulian geometric pottery, which is unknown in Etruria.

Indeed, so far as present evidence avails, and allowing that it is dangerous to prophesy in regard to a region only partially explored, Etruscan influence on the Adriatic coast was very slight and unimportant. A tumulus of the 7th century found at Fabriano is almost entirely Etruscan in its contents, but as yet this is an isolated example. A certain amount of trade was undoubtedly carried on across the Apennines, but there is little in the general complex of Picene life which suggests a strong Etruscan impress. On the contrary, it remains a curiously individual and virile civilization, in spite of its many borrowings. The backbone of Picene commerce was constituted by a lively trade with Istria, which may be clearly traced by means of a comparative study of the objects found in the graves. Nothing, except the existence of a trade-system which centred at the head of the Gulf of Venice, could explain the remarkable circumstance that, in places as far apart as the Italian lakes, Istria, Picenum and Bosnia, there have been found torques, pendants and amulets so precisely similar that they must have been distributed by the same firm of agents.

See E. Brizio in *Monumenti Antichi,* vol. v.; D. Randall-MacIver, *The Iron Age in Italy* (1927); and for a literary treatment from other points of view, F. von Duhn, *Italische Gräberkunde,* vol. i. (1924). (D. R.-M.)

PICENUM, a district of ancient Italy, situated between the Apennines and the Adriatic, bounded north by the Senones and south by the Vestini. The whole territory was divided up among Latin-speaking settlers by the Lex Flaminia in 232 B.C.

It was in Picenum (at Asculum) that the Social War broke out in 90 B.C. Under Augustus it formed the fifth region of Italy, and included twenty-three independent communities. It was reached from Rome by the Via Salaria and the Via Caecilia.

At the end of the 2nd century A.D. the north-eastern portion of Umbria acquired the name Flaminia, from the high road. For the time it remained united with Umbria for administrative purposes, but finally passed to Picenum in the time of Constantine, and acquired the name of *Flaminia et Picenum Annonarium,* the main portion of Picenum being distinguished as *Suburbicarium.* When the exarchate of Ravenna was founded the part of Picenum Annonarium near the sea became the Pentapolis Maritima, which included the five cities of Ariminum, Pisaurum, Fanum Fortunae, Sena Gallica and Ancona. The exarchate was seized by Luitprand in 727, and Ravenna itself was taken by Aistulf in 752. In 753, however, the Emperor Pepin handed it over to the pope, a grant confirmed by Charlemagne.

PICHEGRU, CHARLES (1761–1804), French general, was born at Arbois, or at Les Planches, near Lons-le-Saulnier, on Feb. 16, 1761. His father was a labourer, but the friars of Arbois gave the boy a good education, and the Père Partault took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. At the Revolution he became leader of the Jacobin party in Besançon, and when a regiment of volunteers of the department of the Gard marched through the city he was elected lieut.-colonel. Quickly promoted to the command of the army of the Rhine, in co-operation with Hoche and the army of the Moselle, Pichegru reconquered Alsace and forced the lines of Haguenau and relieved Landau. In Dec. 1793 Hoche was arrested and Pichegru became commander-in-chief of the army of the Rhine-and-Moselle, succeeding Jourdan in the army of the North in Feb. 1794.

It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated Clerfayt at Cassel, Menin and Courtrai, while Moreau, his second in command, defeated Coburg at Tourcoing in May 1794; then after a pause, during which Pichegru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselaer and Hooglede, while Jourdan came up with the new army of the Sambre-and-Meuse, and utterly routed the Austrians at Fleurus on June 27, 1794. Pichegru began his second campaign by crossing the Meuse on Oct. 18, and after taking Nijmwegen drove the Austrians beyond the Rhine. Then, instead of going into winter-quarters, he prepared his army for a winter campaign. On Dec. 28 he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on Jan. 19 and Amsterdam on Jan. 20, and soon occupied the whole of Holland. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of "Sauveur de la Patrie," subdued the *sans-culottes* of Paris, when they rose in insurrection against the Convention on 12 Germinal (April 1). Pichegru then took command of the armies of the North, the Sambre-and-Meuse and the Rhine, and crossing the Rhine in force took Mannheim in May 1795.

When his fame was at its height he allowed his colleague Jourdan to be beaten, betrayed all his plans to the enemy, and took part in organizing a conspiracy for the return of Louis XVIII. His intrigues were suspected, and when he offered his resignation to the Directory in Oct. 1795, it was promptly accepted. He retired in disgrace. In the Council of Five Hundred (May 1797) he was the royalist leader, and planned a *coup d'état,* but on the 18th Fructidor he was arrested, and deported to Cayenne in 1797. Escaping, he reached London in 1798, and served on General Korsakov's staff in the campaign of 1799. He went to Paris in Aug. 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but was arrested on Feb. 28, 1804, and on April 15, was found strangled in prison. He was a man of enormous strength and great personality.

There is no really good life of Pichegru; perhaps the best is J. M. Gassier's *Vie du général Pichegru* (1815). For his treason, trial and death, consult Montgaillard's *Mémoires concernant la trahison de Pichegru* (1804); Fauche-Borel's *Mémoires;* Savary, *Mémoires sur la mort de Pichegru* (1825); and G. Pierret, *Pichegru, son procès et sa mort* (1826); and Sir J. R. Hall, *General Pichegru's Treason* (1915).

PICHER, a city of Ottawa county, Oklahoma, U.S.A., in the north-eastern corner of the state, near the Kansas boundary; on Federal highway 66 and served by the Miami Mineral Belt and electric railways. The population was 9,676 in 1920 (99% native white) and was estimated locally at 18,000 in 1928. It is one of the principal mining centres in the "Tri-State region," which produces 60% of the zinc and 15% of the lead mined in the United States. The city is built entirely on leased land, owned by the Quapaw Indians. The first mine was opened in 1915. The city was incorporated in 1920, and has grown rapidly.

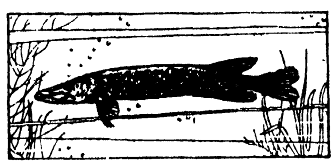
PICKENS, ANDREW (1739–1817), American soldier in the Revolutionary War, was born in Paxton, Pa., on Sept. 19, 1739. His family settled at the Waxhaws (in what is now Lancaster county), S.C., in 1752. He fought against the Cherokees in 1761 as a lieutenant. In the Revolutionary War he rose to brigadier-general (after Cowpens) in the South Carolina militia. On Feb. 14, 1779, with 300–400 men, he surprised and defeated about 700 Loyalists on Kettle Creek, Wilkes county, Ga.; and later in the same year at Tomassee defeated the Cherokees, who were allied with the British. Upon the surrender of Charleston (May 1780) he became a prisoner on parole, which he observed rigidly until, contrary to the promises made to him, Maj. James Dunlap plundered his plantation; he then returned to active service. His command (about 150 men) joined Gen. Daniel Morgan immediately before the battle of Cowpens, in which Pickens commanded an advance guard (270–350 men from Georgia and North Carolina) and twice rallied the broken American militia; for his services Congress gave him a sword. With Col. Henry Lee he harassed Lieut.-col. Banastre Tarleton, who was attempting to gather a Loyalist force just before the battle of Guilford court house; and with Lee and others, he captured Augusta (June 5, 1781) after a siege. At Eutaw Springs (Sept. 8, 1781) he commanded the left wing and was

wounded. In 1782 he defeated the Cherokees again. After the war he was active for several years in state politics, and in 1793–95 was a representative in Congress. He died in Pendleton district, S.C., on Aug. 17, 1817. He married in 1765 Rebecca Calhoun, an aunt of John C. Calhoun. Their son, ANDREW PICKENS (1779–1838), served as a lieutenant-colonel in the War of 1812, and was governor of South Carolina in 1816–18.

See E. B. Pickens, "Life of General Pickens," *Journal of Amer. Hist.*, vol. xviii., pp. 131–136 (1924).

PICKENS, FRANCIS WILKINSON (1805–1869), American politician, was born in Togadoo, St. Paul's parish, S.C., April 7, 1805, son of Andrew Pickens (1779–1838) and grandson of Gen. Andrew Pickens (1739–1817). He was educated at Franklin college, Athens, Ga., and at South Carolina college, Columbia, and was admitted to the bar in 1829. In 1832 he was elected to the State house of representatives, where he submitted a report denying the right of Congress to exercise any control over the States. He was a Democratic member of the national house of representatives in 1834–43, served in the South Carolina senate in 1844–45, was U.S. minister to Russia in 1858–60, and in 1860–62 was governor of South Carolina. He strongly advocated the secession of the Southern States; signed the South Carolina ordinance of secession; sanctioned firing upon the "Star of the West" (Jan. 9, 1861), which was bringing supplies to Anderson, and the bombardment of Ft. Sumter. He died at Edgefield, S.C., on Jan. 25, 1869

PICKEREL, the name used, especially in America, where there are several species which never reach a large size, for certain small pike (*q.v.*); in England small specimens of *Esox lucius*, the only species represented, are usually termed jack.



THE EASTERN PICKEREL, AVERAGE LENGTH ABOUT 2 FEET

PICKERING, EDWARD CHARLES (1846–1919), American physicist and astronomer, was born in Boston on July 19, 1846. He was graduated in 1865 in the Lawrence Scientific school of Harvard, where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology, where he established the first laboratory in America, in which students were instructed by actual contact with physical instruments and measurements. In 1876 he was appointed professor of astronomy and director at the Harvard college observatory. In 1877 when most observatories were devoting themselves to the old "astronomy of position" Prof. Pickering, who was a physicist rather than an old school astronomer, chose as his particular field of labour the photometry of the stars, thus presaging the trend of the new astronomy along lines of physics. He invented the meridian photometers (*see* PHOTOMETRY: *Stellar*), with which the brightness of more than 45,000 stars has been measured at Cambridge and Arequipa (Peru) observatories, and the resulting system generally adopted as an international standard. Prof. Pickering, personally, made more than 1,500,000 photometric settings.

Through the establishment of an observatory at Arequipa (1891), after two years of study it became possible to include measurements made on the stars throughout the Southern heavens within the scope of the Harvard college observatory's work.

The work of the observatory under Prof. Pickering may be summarized as including photometry, in which photometric magnitudes for 80,000 stars have been determined; a scale of photographic magnitude; a system of classification of variable stars; and a system of stellar spectroscopy which has been universally adopted. As a result of Pickering's work, the Harvard "photographic library" of stars contains more than 250,000 photographic plates. He died at Cambridge, Mass., on Feb. 3, 1919.

For bibliography and further biographical material see *Biographical Memoirs of National Academy of Sciences*, vol. vii., pp. 52–57. *See* also *Proceedings of the American Academy of Arts and Sciences*, vol. lvii., pp. 502–506 (Boston, 1922); *Monthly Notices of Royal Astronomy Society*, vol. viii., pp. 360–365.

PICKERING, TIMOTHY (1745–1829), American politician, was born at Salem, Mass., on July 17, 1745. He graduated from Harvard college in 1763 and was admitted to the bar in 1768. In the pre-Revolutionary controversies he identified himself with the American Whigs; and in 1776 he was a representative from Salem in the general court of Massachusetts. Early in 1775 he published *An Easy Plan of Discipline for a Militia*. In the same year he became judge of the court of common pleas for Essex county, and in the winter of 1776–77 he led an Essex regiment of volunteers to New York. He subsequently served as adjutant general, later as quartermaster general and was also a member of the board of war. In April, 1783, he drew up a plan for the settlement of the North-West territory, which provided for the exclusion of slavery. In 1785 he became a commission merchant in Philadelphia; but in Oct., 1786, soon after the legislature of Pennsylvania had passed a bill for erecting Wyoming district into the county of Luzerne, he was commissioned to organize the county. He offered to purchase for himself the Connecticut title to a farm, and in 1787 he was appointed a member of a commission to settle claims according to the terms of an act, of which he was the author, confirming the Connecticut titles (*see* WYOMING VALLEY and WILKES-BARRE). In 1790 he negotiated a peace with the Seneca Indians, and he concluded treaties with the Six Nations in 1791–94. Under Washington he was postmaster general (1791–1795), secretary of war (1795), and after December, 1795, secretary of state, to which position he was reappointed (1797) by Adams. In 1783, while he was quartermaster general, he had presented a plan for a military academy at West Point, and, as secretary of war, he supervised the West Point military post with a view to its conversion into a military academy. As head of the state department he soon came into conflict with Adams. His hatred of France made it impossible for him to sympathize with the president's efforts to settle the differences with that country peaceably. He was dismissed, after refusing to resign, in 1800. Returning to Massachusetts, he was elected a United States senator in 1803–11 and a member of the House of Representatives in 1813–17. As an ultra Federalist—he was a prominent member of the group known as the Essex junto—he strongly opposed the purchase of Louisiana and opposed the War of 1812. He died at Salem, Mass., on Jan. 29, 1829.

The standard biography is that by his son, Octavius Pickering (1791–1868), and C. W. Upham, *The Life of Timothy Pickering* (Boston, 1867–1873). In the library of the Massachusetts Historical Society at Boston, there are 62 manuscript volumes of the Pickering papers, an index to which was published in the *Collections* of the society, 6th series, vol. viii. (Boston, 1896).

His son, JOHN PICKERING (1777–1846), graduated at Harvard in 1796. He wrote on the languages of the North American Indians. He was a founder of the American Oriental Society and published a *Comprehensive Dictionary of the Greek Language* (1826).

Timothy Pickering's grandson, CHARLES PICKERING (1805–1878), was naturalist to the Wilkes exploring expedition of 1838–42, and in 1843–45 travelled in East Africa and India.

PICKERING, WILLIAM HENRY (1858–), American astronomer, was born in Boston, Mass., on Feb. 15, 1858, and in 1879 graduated at the Massachusetts Institute of Technology. He served as an assistant and instructor in physics at his Alma Mater from 1880 to 1887, and then became an assistant in astronomy at the Harvard college observatory. In 1890 he was made assistant professor of astronomy. He led expeditions for observing total solar eclipses to Colorado, 1878; Grenada, West Indies, 1886; California, 1889; Chile, 1893; and Georgia, 1900. While in southern California in 1889 he selected the Mt. Wilson site and established a temporary observatory there. In 1891 he established the Arequipa station of the Harvard observatory in Peru. He also established a meteorological station at an altitude of 16,650ft. upon Mt. Chahocoman, and accomplished the ascent of El Miste, 19,400 feet. He surveyed and determined the altitude of many other Peruvian mountains and returned to the United States by way of the Straits of Magellan in 1893. In 1894 he erected the observatory and telescope for Dr. Percival Lowell (*q.v.*) at Flagstaff, Ariz., and in 1900 erected a station for the Harvard observatory at Mandeville, Jamaica, in the West Indies. In 1899 he discovered Phoebe, and afterwards Themis,

9th and 10th satellites of Saturn, and demonstrated why their revolution was opposite in direction to all the other satellites. In 1904 he again went to California to make observations of the moon, in 1905 to Hawaii, and in 1907 to the Azores to compare their crater formations with those in the moon. His work in planetary photography and photometry was especially notable. In later years he turned more and more to the study of Mars.

Besides many papers in astronomical journals (*see* especially *Popular Astronomy*), he wrote *A Walking Guide to the Mt. Washington Range* (1882); *Investigations in Astronomical Photography* (1895); *Visual Observations of the Moon and Planets* (1903); *An Atlas of the Moon* (1903); *Lunar and Hawaiian Physical Features Compared* (1906); *A Search for a Planet Beyond Neptune* (1909); *A Statistical Investigation of Cometary Orbits* (1911); *Mars* (1921).

PICKERING, urban district and town in the North Riding of Yorkshire, England, 32 m. N.E. by N. from York by the L.N.E. railway, on which it is an important junction. Pop. (1921) 3,503. The town lies at the foot of the York moors at the entrance to one of the river ways into the Vale of Pickering. It is the centre of an agricultural and pastoral area with a broad belt of arable land in the vale given to cereal and fodder crops. North of Pickering is a moorland grazing area. Agricultural implements are manufactured there, and limestone and freestone are quarried in the vicinity.

A castle existed at Pickering before the Conquest, and the present ruin on a hill to the north of the town is partly Norman but mainly 14th century in style. A fragmentary keep and several towers remain. It was the prison of Richard II. before his confinement at Pontefract. During the Civil War, it was held by the royalists and suffered greatly in siege.

PICKETING: *see* TRADE UNIONS.

PICKETT, GEORGE EDWARD (1825–1875), American Confederate soldier, born at Richmond, Va., Jan. 25, 1825. Upon graduation at West Point in 1846 he was assigned to the 8th United States infantry; served with distinguished valour in all the battles of Gen. Scott in Mexico, including the siege of Vera Cruz and the storming of Chapultepec, where, it is said, he was first to scale the parapets and unfurl the American flag over the castle. After peace was restored, Pickett was transferred to Washington Territory where he was destined to play an important role in the north-west boundary controversy. In 1859 he was ordered to occupy San Juan island, where he prevented the landing of a superior force of British troops. On the outbreak of the Civil War he resigned his command (June 1861) and offered his services to the Confederacy. He was commissioned captain and after a short time was made a colonel. In Feb. 1862 he was appointed a brigadier-general and assigned to the command of a Virginia brigade of infantry. During that year he rendered able service in the battles of Williamsburg, Seven Pines, Gaines Mill and Fredericksburg. While leading his men at Gaines Mill he was severely wounded, but upon returning to his command in September he was made a major-general. At Gettysburg, his division was held in reserve until July 3 when it led the attack on Cemetery hill. The charge of Pickett's men is one of the most famous episodes of military history. Over three-quarters, 3,393 officers and men out of 4,500 were left on the field. He subsequently commanded the Confederate forces in North Carolina but after the failure to take Newbern, he turned north to defend Petersburg. His troops participated in the assault on Grant's line at Cold Harbor and performed excellent service in the closing campaign of 1865 at Dinwiddie court house and Five Forks. After the Civil War he went to Richmond and later to Norfolk where he was engaged in the insurance business. His death occurred in Norfolk on July 30, 1875.

See La Salle Corbell Pickett, *Pickett and his Men* (1899, rev. ed., 1913), and A. C. Inman, editor, *Soldier of the South; Gen. Pickett's War Letters to His Wife* (1928).

PICKFORD, MARY (1893–) (stage name of Gladys Smith), American motion picture actress, born at Toronto, Canada, April 8, 1893. Her first stage appearance was at the age of five; at eight she went on tour. She went to New York under the auspices of Belasco, creating the part of Betty Warren in *The Warrens of Virginia*. Her first motion picture work was undertaken with D. W. Griffith as an extra; but she returned to Belasco, taking the part of Juliet in *A Good Little Devil* at the Republic theatre in New York. In 1913 she returned to the screen with Famous Players Company, and rose to the first rank. In 1916 the Mary Pickford Film Corporation was organized and she received a salary higher than that paid to any other motion picture actress. In 1918 she became an independent producer and went to California. In 1919 she was the prime mover in the formation of the United Artists Corporation. She married Douglas Fairbanks, motion picture actor and producer, on March 28, 1920.

PICKLE. In the wider sense the term "pickle" is applied to any saline or acid preservative solution; in the narrower to vegetables preserved in vinegar. The word appears to be an adaptation of the Dutch *pekel*, brine, pickle; *cf.* Ger. *Pökel*. A solution of copper or zinc sulphate is used as a "pickle" for railway-sleepers or other wood, a brine containing salt and saltpetre as a preservative for meat, lime-water as "pickle" for eggs. Domestic pickles are made from small cucumbers, onions, cauliflowers, cabbages, mangoes, unripe walnuts and other fruits and vegetables, by either steeping or boiling them in salt-brine and vinegar.

PICO, an island in the Atlantic ocean, belonging to Portugal, forming part of the Azores archipelago; pop. about 25,000 and area 175 sq. miles. Pico rises to the height of 7,613 feet. The soil is of volcanic origin. The island was formerly famous for its Fayal wine (Fayal is, however, an adjacent island), but in 1852 the vines were destroyed by disease. Similar destruction affected the fruit trees (orange) and a period of emigration followed. The distress was alleviated by the planting of fig-trees and the cultivation of apricots. The chief town is Lagens do Pico.

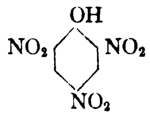
PICO DELLA MIRANDOLA, GIOVANNI, COUNT (1463–1494), Italian philosopher and writer, the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory not far from Ferrara, afterwards absorbed in the duchy of Modena, was born on Feb. 24, 1463. In his fourteenth year Pico went to Bologna, where he studied for two years, and was much occupied with the Decretals. He then spent seven years wandering through Italy and France and collecting a precious library. Besides Greek and Latin he knew Hebrew, Chaldee and Arabic; and his Hebrew teachers introduced him to the Kabbalah. He settled in 1486 at Rome, where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of philosophy and theology, but the pope prohibited them, and Pico had to defend the impugned theses in an elaborate *Apologia*. His personal orthodoxy was subsequently vindicated by Alexander VI. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries and it was by him that Reuchlin was led into the same delusive path.

In his 28th year Pico published the *Heptaplus*, a mystical exposition of the Creation. Next he planned a great seven-fold work against the enemies of the Church, of which only the section against astrology was completed After leaving Rome he again lived a wandering life, often visiting Florence, to which he was drawn by his friends Politian and Marsilius Ficinus, and where also he came under the influence of Savonarola. Three years before his death he parted with his share of the ancestral principality, and designed, when certain literary plans were completed, to give away all he had and wander barefoot through the world preaching. But these plans were cut short by a fever which ended in his death at Florence on Nov. 17, 1494.

His works were published at Bologna in 1496 by his nephew, with a biography, which was translated by Sir Thomas More as *Life of John Picus, Earl of Mirandola*, in 1510. *See* Walter Pater's *Renaissance* (1878); the study by J. Rigg, prefixed to the reprint of More's *Life* in the "Tudor Library" (1890). Mortetani, *La filosofia cabbalistica di Pico della Mirandola* (Empoli, 1898); and A. Levy, *Die Philosophie Picos della Mirandola* (1908).

PICRIC ACID or **LYDDITE,** is a yellow crystalline solid melting at 122·5° C and owes its name to the intensely bitter and persistent taste of its yellow aqueous solution. As experiments regarding the use of picric acid as a high explosive were once conducted at the town of Lydd (Sussex), the name Lyddite became attached to the acid. The term melinite is employed in France and Germany, and shinosite indicates the Japanese variety of this

explosive. As its graphic formula (inset) indicates, it is a benzenoid derivative with three hydrogen atoms of the benzene nucleus replaced by nitro (NO_2) groups, and one replaced by a hydroxyl (OH) group, whence its name and formula 2:4:6 trinitrophenol $HO{\cdot}C_6H_2(NO_2)_3$. It is a typical example of a nitro-compound of the aromatic series, and was formerly employed as an acid dyestuff giving yellow shades on wool or silk. Although acting as a poison when administered in quantities exceeding a few milligrams, its saturated aqueous solution may safely be applied to burns and scalds with the object of subduing the pain, which it effects by paralysing the sensory nerve endings.



The ordinary method of manufacturing picric acid is to dissolve phenol in strong sulphuric acid thus making a phenolsulphonic acid, $C_6H_5OH+H_2SO_4=HO{\cdot}C_6H_4{\cdot}SO_3H$, which on treatment with a moderate excess of nitric acid regenerates sulphuric acid, and at the proper temperature gives finally trinitrophenol. This separates as an oily liquid which becomes solid on cooling. It is washed with cold water to remove excess of acids and then dissolved in hot water, from which it crystallizes in yellow scales, plates or needles, depending on the concentration of solution The picrates of ammonia and of the alkali metals sodium and potassium are most soluble, whereas the lead salt and a few others are sparingly soluble in water Certain organic bases, such as acridine, give more insoluble salts than metals When heated above its melting point picric acid puffs or burns with a smoky flash: a small amount may sublime as a yellow powder This burning does not appear to be dangerous when only small quantities are dealt with unless the external heating be rapid and extensive, so that the whole bulk under experiment is heated up; in that case the simple burning passes over into a kind of detonating decomposition. The metallic salts of picric acid are most liable to this violent form of explosion, in fact it is almost the only form of explosion they exhibit either on heating or under percussion The picrates of lead, bismuth and other heavy metals are extremely sensitive to friction or percussion as well as heating, especially when dry The pure acid itself is not dangerously sensitive to percussion, although a powerful and quick glancing blow will often induce decomposition The explosion of a very small amount of a picrate—as the lead or potassium salt—in contact with the acid, especially if the latter be in a compact state, generally induces a complete detonation. At one time picric acid was much in favour either as an ingredient of an explosive mixture with some special objective use or alone Among the mixed explosives containing picric acid may be mentioned Brugères powder, a mixture of 54 parts of ammonium picrate and 45 of potassium nitrate; Designolles' powder, potassium picrate, potassium nitrate and charcoal; and Emmensite, of similar composition, suggested by Mr Emmens, U.S.A. Many others were designed for blasting or similar purposes. (W. R. Ho.)

PICRITE, in petrology, an intrusive igneous rock of ultrabasic composition somewhat similar to peridotite (*q.v.*). The name, given by Tschermak in 1866, is derived from πικρός, "bitter," owing to the high percentage of magnesia (bitter earth) these rocks contain. The picrites are dark, heavy rocks largely composed of olivine and augite, with a small but variable amount of plagioclase felspar. Hornblende and biotite may also be present The picrites usually occur in sills or sheets, and seldom in large plutonic masses (unlike peridotites). Varieties of picrite include augite, enstatite and hornblende picrite.

The minerals of picrites are very frequently decomposed Serpentine partially or wholly replaces olivine, while hornblende (pilite), talc and chlorite appear as secondary products after the same mineral. Augite passes into hornblende or chlorite, and the essential felspar is often represented by epidote, prehnite and white mica. In some picrites, as in the peridotites, a "lustre mottling" is given by the poikilitic inclusion of olivine grains in large crystals of augite or hornblende. In the porphyritic varieties a residual brown glass may be present. Such rocks are known as picrite-porphyrites.

Many picrites clearly possess alkaline affinities. Thus the augite picrites of the Midland valley of Scotland and of the type locality in Moravia contain interstitial analcime and are closely related to the teschenites with which they are associated. Other picrites are more clearly "calc-alkaline" being associated with diorites or dolerites. The hornblende picrites of Carnarvonshire, Anglesey and other places belong here. In the Devonian rocks of the Fichtelgebirge and Nassau picrites accompany dolerites and proterobases, as they do also in Cornwall and Devon. The term picrite-basalt is reserved for felspar-poor basalts rich in olivine. (C E. T.)

PICROTOXIN, a neutral principle obtained from the *Cocculus indicus*, which is the fruit of the *Anamirta paniculata*. It is used in medicine externally as an antiparasitic. Internally it has been successfully used to check the night-sweats of phthisis. In large doses it is a powerful poison, causing unconsciousness, delirium, convulsions, gastro-enteritis and stimulation of the respiratory centre followed by paralysis, from which death sometimes results. Formerly *Cocculus indicus* berries were sometimes added to beer to increase the intoxicating effects. The chemical formula of picrotoxin is $C_{15}H_{16}O_6{\cdot}H_2O$.

PICTISH. The language of the ancient Picts is of uncertain origin and of doubtful affinity. "The Picts have left us a number of inscriptions in the Ogham character. No attempt to interpret these inscriptions as any form of Celtic has produced anything but bosh. Whatever may have been the Pictish language, these inscriptions assure us that it was certainly not Celtic" (R A. S. Macalister in *Antiquity* II., 7, 1928, p. 373.) Examination of the symbols found upon monumental stones in Pictland suggests analogies with certain elements in Bronze age sculpturings—a highly probable affinity if the Picts were the survivors of Bronze age aborigines, influenced by La Tène culture

The term *Pict* itself may be connected with the Latin *Pictones* and *Pictari* of Gaul In Irish they are known as *Cruithne*, in Welsh as *Prydyn,* which (*cf.* Prydein, or British) significantly resembles the earliest Greek name for the British Isle, *Pretonnic Islands.* From the matrilineal succession of their chiefs (the records being doubtful) it has been inferred that their social structure differed from that of other Gaelic speaking peoples Pictish extended to the north of Ireland, and was finally ousted by the Goidelic speech of the Scots, which was derived from Ireland

See T. R. Holmes, *Caesar's Invasion of Britain* (1907)

PICTOGRAPHY. In the history of writing a very large number of conventional marks are demonstrably reductions from still older forms, which have often developed out of pictographs. Pictography has left its traces in all parts of the world, but was most widely developed in the New World as a system lasting down to modern times.

Very simple pictures are drawn upon birch bark, indicating by their order the subjects in a series of song-chants with sufficient precision to enable the singer to recall the theme of each in his recitation. An account can be kept of sales or purchases by representing in perpendicular strokes the number of items, and adding at the end of each series a picture of the animal or object to which the particular series refers. Thus three strokes followed by the picture of a deer indicate that the hunter has brought three deer for sale. A conventional symbol (a circle with a line across it) is used to indicate a dollar, a cross represents ten cents, and an upright stroke one cent, so that the price can be quite clearly set forth. This practice is followed in many other parts of the world In clay tablets discovered by Sir Arthur Evans at Knossos, in Crete, a somewhat similar method of enumeration is followed; while at Athens conventional symbols were used to distinguish drachmae and obols upon the revenue records

In comparatively recent times the Dakota Indians invented a chronological table, or winter count, wherein each year is recorded by a picture of some important event which befell during that year. In these pictures a considerable amount of symbolism was necessary. A black upright stroke indicates that a Dakota Indian was killed, a rough outline of the head and body spotted with blotches indicates that in the year thus indicated the tribe suffered from smallpox Sometimes, in referring to persons, the symbol is of the nature of a rebus. Thus, Red Jacket, an Indian chief, was killed in the winter of 1807–8, this fact is recorded by a red coat

with two arrows piercing it and blood dripping. There is, however, nothing of the nature of a play upon words intended. Here the Mexicans proceeded a stage further, as in the often quoted case of the name of Itz-coatl, literally knife-snake, which is ordinarily represented by a reptile (*coatl*) with a number of knives (*itz*) projecting from its back. It is, however, also found divided into three words, itz-co-atl—knife-pot-water—and represented by a different picture accordingly. The Mexicans, moreover, to indicate that the picture was a proper name, drew the upper part of the human figure below the symbol, and joined them by a line, a practice adopted also amongst their northern neighbours when, as in names like Little-Ring, the representation would hardly be sufficiently definite. Simple abstract notions could also be expressed in this picture-writing. Starvation or famine was graphically represented by a human figure, with the ribs showing prominently. A noose amongst the Mexicans was the symbol for robbery, though more logically belonging to its punishment. In a Californian rock-painting sorrow is represented by a figure from whose eyes drop tears. This could be abbreviated to an eye with tears falling from it, a form recorded by Schoolcraft as existing amongst the Ojibwa Indians. The symbol is so obvious that it is found with the same value among Egyptian hieroglyphics.

To the more elaborate civilizations of the Old World, the development of writing from pictography can be ascribed—the Assyrians (*see* CUNEIFORM), Egyptians (*see* EGYPT) and Chinese (*see* CHINA). Here more complex notions had to be expressed. The development of the system can be traced through many centuries, and shows a tendency to conventionalize the pictorial symbols employed. Out of conventionalized forms develop (*a*) syllabaries, (*b*) alphabets. As regards the latter the historical evolution is traced in the article ALPHABET. The account given under CHINA (*language*) gives a good idea of the development of a syllabary from pictographic writing.

PICTON, SIR THOMAS (1758–1815), British general, born at Poyston, Pembrokeshire, joined the army in 1773 as an ensign. On the disbandment of the 75th regiment in 1783 Picton quelled a mutiny amongst the men by his prompt personal action and courage. After living in retirement on his father's estate for nearly twelve years, he went out to the West Indies in 1794. He took part in the capture of St. Lucia (for which he was promoted lieutenant-colonel) and in that of St. Vincent. After the reduction of Trinidad Abercromby made him governor of the island. He administered the island with such success that the inhabitants petitioned against the retrocession of the island to Spain. In October 1801 he was gazetted brigadier-general. But by this time the rigour of his government, as reported by his enemies, had led to a demand by humanitarians at home for his removal. He was charged with permitting the application of torture under the Spanish law which he had to administer. Colonel William Fullarton (1754–1808) procured the appointment of a commission to govern the island, with Picton as its junior member. Picton resigned, and on his return to England in December 1803 he was arrested by order of the privy council. He was tried in the court of king's bench before Lord Ellenborough in 1806 on one of the charges, on which the court returned a merely technical verdict of guilty, which was superseded in 1808 by a special verdict on retrial. In 1810, at Wellington's request, he was appointed to command a division in Spain. For the remaining years of the Peninsular War, Picton was one of Wellington's principal subordinates. The commander-in-chief, it is true, never reposed in him the confidence that he gave to Beresford, Hill and Craufurd, but in the resolute, thorough and punctual execution of a well-defined task Picton had no superior in the army. His début was unfortunate. On the Coa in July 1810 Craufurd's division became involved in an action, and Picton, his nearest neighbour, refused to support him, as Wellington's direct orders were to avoid an engagement. Details of the incident will be found in Oman, *Peninsular War,* vol. iii. Shortly after this, however, at Busaco, Picton found and used his first great opportunity for distinction. He repulsed the French attack with skill and resolution. He fought at Fuentes d'Onor, with Craufurd he stormed the breaches at Ciudad Rodrigo, and in command of the 3rd division was at the storming of Badajoz. Wounds compelled a temporary absence in England, but he again commanded the 3rd division at Vittoria, in the battles of the Pyrenees, and at Orthez and Toulouse.

On June 24, 1814, Picton received for the seventh time the thanks of the House of Commons for his great services and in 1815 he was made a G.C.B. Picton was severely wounded at Quatre Bras, but concealed his wound and retained command of his troops, and at Waterloo, two days later, was shot through the head by a musket ball. His body was brought home to London, and buried in the family vault at St. George's, Hanover Square. A monument was erected to his memory in St. Paul's Cathedral.

See Robinson's *Life of Sir Thomas Picton* (London, 1836), with which, however, compare Napier's and Oman's histories of the Peninsular War as to controversial points.

PICTOU, a seaport, port of entry, and capital of Pictou county, Nova Scotia, 90 m. N.E. by N. of Halifax, on a branch of the Canadian National railway. Pop. (1921) 2,988. It has several valuable industries, and is the shipping port for the adjacent coal-mines. The Academy was founded in 1818.

PICTS, the name given to an ancient Celtic race of the Stone Age inhabiting Britain (*q.v.*) and later the Highlands. In a battle of 640 they defeated the Britons, and for many years the inhabitants of the Roman provinces were exposed to devastating raids by the Picts and Scots. *See* STRATHCLYDE. They were finally conquered in 846 by Kenneth (*q.v.*) MacAlpine.

PICUS, the Latin name of the woodpecker. This bird being sacred to Mars was widely reverenced in ancient Italy. Occasionally Picus is met with as a minor deity, associated with Faunus, as in the (late and artificial) legend of Picus, Faunus and their capture by Numa, Ovid, *Fast.*, iii, 291 ff. Like many of the minor deities, Picus was rationalized into an ancient king, and a pedigree was made out as follows: Saturnus (*q.v.*), Picus, Faunus (*q.v.*), Latinus (*e.g.* Virgil, *Aen.*, vii. 45–49). Hence, in various late accounts (*a*) as Saturnus was identified with Cronus, Picus was made equivalent to Zeus; *see* Halliday in *Class. Rev.*, xxxvi. p. 110 (1922). (*b*) For some unknown reason, Varro (*ap.* Augustine, *de ciuit. Dei*, xviii., 15) interpolated into the genealogy, as father of Picus, Stercutius (Sterces, Sterculius, the spirit of manuring fields). (*c*) Picus is confused with Picumnus, a minor deity worshipped along with Pilumnus the spirit of the pestle (*pila*) (Nonius Marcellus, p. 834, Lindsay, citing Macer). (*d*) Ovid tells a romantic story to the effect that Picus loved a nymph Canens ("the Singer"), repulsed the advances of Circe (*q.v.*) and was turned by her into a woodpecker (*Met.*, xiv. 312 ff.). This seems to be Ovid's own invention; most authors (as Virgil, *Aen.*, vii. 189, Plutarch, *quaest. Rom.* 21) who tell the story of the metamorphosis, say Circe was his wife.

See Carter in Roscher's *Lexikon,* art. "Picus."

PIDDOCK, a bivalve mollusc which bores into chalk cliffs below the low-water line. Piddocks belong to the genus *Pholas,* of the class Lamellibranchia (*q.v.*), and are remarkable in being phosphorescent. (*See* PHOSPHORESCENCE: *Animal.*) The shell is curiously shaped in adaptation to their boring habit.

PIDGIN ENGLISH, the *lingua franca* of the seaports of China and the Straits Settlements, a jargon, mainly of corrupted English words following Chinese idiomatic usage. It is employed as a means of communication between foreigners and Chinese. "Pidgin" is the Chinese corruption of "business."

PIECE-OF-EIGHT, an obsolete Spanish coin, properly the *piastre* or *peso,* commonly also called a dollar, coined of silver, and divided into eight *reals,* whence "piece-of-eight." Its value was four shillings. In 1797, when the Bank of England suspended payment, millions of these coins were put into British circulation, countermarked with a small oval bust of George III. The piece-of-eight was current in the Spanish-American colonies.

PIECE-WORK, a term used to describe the method of industrial remuneration in which the worker is paid by the piece or job. In practice, where piece-work is arranged in trades that are organized, the payment per unit of work is arranged by negotiation between the employers and employed, as for example, in the English cotton industry. Very often the agreements arrived at

are extremely complicated, with various percentage variations upon a basic rate, so that the expression of piece-rate becomes very difficult for one outside the industry to understand. Agreements as to piece-work are often subject to a minimum wage arrangement. *See* Wage Systems in Industry.

PIEDMONT (pĭ-ăd'mŏnt), is a territorial division of north Italy, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara and Torino (Turin) to which Aosta and Vercelli were added in 1927. It has an area of 11,340 sq.m. The people are chiefly engaged in agriculture—which is helped by irrigation. In 1927, the products were:

	Area	Tons
Wheat	833,000	461,800
Rye	124,000	56,980
Oats	41,000	22,040
Rice	169,400	362,580
Maize	373,250	297,700
French beans	87,000	18,660
Sugar beet	3,000	31,060
Hemp	7,100	2,270
Garden produce	10,250	58,760
Potatoes	73,500	211,500
Cocoons	.	6,270
Hay		2,668,100
Vines	703,750	651,600 (grapes) 8,087,000 (wine—gallons)
Fruits (various)		114,170
Chestnuts	263,375	59,980

Many are also occupied in the reeling and throwing of silk and in the manufacture of cotton (no fewer than 50,000 workers, of whom 37,000 are women), woollens and clothing; there are also considerable manufactures at Turin, Savigliano, etc. The Piedmontese dialect has been rather strongly influenced by French. The total population of Piedmont was in 1901 3,407,493, in 1921, 3,527,847. There are numerous summer resorts in the Alpine valleys. The chief railway centres are Turin, communicating with the Mont Cenis line, and with the Riviera by the railway over the Col di Tenda (in process of construction). The communications with Liguria are difficult owing to the approach of the mountains to the coast, but the electrification of the lines from Genoa to Turin and Milan has greatly improved the travelling facilities of this region.

Piedmont (Ital. *Piemonte;* Low Lat. *Pedemons* and *Pedemontium*), in Roman times until 49 B.C. formed a part of Gallia Transpadana, and in Augustus's division of Italy formed with what was later known as Lombardy the 11th region. It formed part of the Lombard kingdom, and it was not till about A.D. 1000 that the house of Savoy (*q.v.*) arose.

See E. Reynolds-Ball, *Unknown Italy: Piedmont and the Piedmontese* (London, 1927); D. Gribaudi, *Il Piemonte nell' antichità classica* (Turin, 1928).

PIEDMONT, a residential city of California, U.S.A., on the heights adjoining Berkeley and Oakland. It has few shops and no factories, and its building regulations prohibit the construction of multiple dwellings. The population was estimated locally at 9,000 in 1928.

PIEDRAS NEGRAS, formerly Ciudad Porfirio Díaz, a northern frontier town of Mexico in the State of Coahuila, 840m. N. by W. from Mexico City, on the Río Grande del Norte, 720ft. above sea-level, opposite the town of Eagle Pass, Texas. Pop. (1921) 14,233. An international bridge connects the two towns, and the Mexican International railway has its northern terminus in Mexico at this point. The town has an important transfer trade with the United States, and is the centre of a fertile district devoted to agriculture and stock-raising. Coal is found in the vicinity. The Mexican Government maintains a custom-house and military post here. The town was founded in 1849.

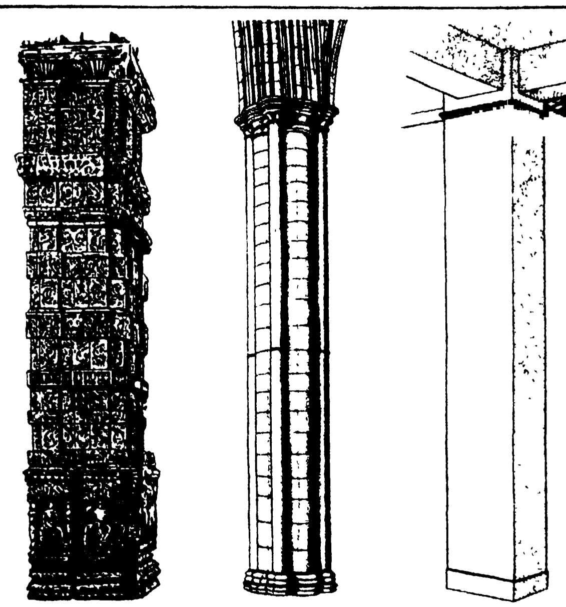
PIENZA, a town of Tuscany, Italy, in the province of Siena, 9 m. west of the town of Montepulciano by road, 1611 ft. above sea-level. Pop. (1921), 1,391 (town); 3,914 (commune). The place was originally called Corsignano and owes its present name to Aeneas Silvius Piccolomini, Pope Pius II. (*q.v.*) who was born here in 1405. The buildings which he caused to be erected by Bernardo Rossellino in 1460–1463 form a noble group of early Renaissance architecture round the Piazza del Duomo. The latter retains Gothic details in the interior, but the facade is simple Renaissance work. The other three sides are occupied by the episcopal and municipal palaces, and the Palazzo Piccolomini; the last, resembling the Palazzo Rucellai at Florence, is the finest, and is well furnished: in front of it is a beautiful fountain, and opposite it the fine Palazzo Ammannati. The canons' house contains a museum with some fine ecclesiastical vestments including an excellent 13th century cope of English origin, and enamels.

PIER. In architecture (*q.v.*) it usually denotes a vertical support in masonry, brickwork or concrete which carries an arch or superstructure. In this sense it is applied both to those portions of a structure which are visible above ground and to isolated or detached supports underground described as foundation piers. The term is sometimes applied to the solid parts of a wall between windows or voids, and also to the isolated masses of brickwork, masonry or concrete to which gates are hung.

Bridge Piers.—In the construction of bridges (*q.v.*) and viaducts, *pier* denotes the solid structure upon which the bridge superstructure (including arches) is supported. Occasionally in the case of high piers supporting viaducts and bridge superstructures the upper portions are constructed of open-braced iron- or steel-work.

Foundation piers for bridges are formed of solid masonry, brickwork or concrete and, sometimes, reinforced-concrete is employed for the purpose. In places where timber is abundant, as in some parts of the United States and Canada, wooden cribs filled with rubble stone or concrete have been used for raising the foundations of piers out of water.

Special provisions must be made for the foundations of piers where the ground is soft for some depth, or loose water-bearing strata are encountered, and especially where the piers of large



Indian Compound Brahmanical Temple Gwalior

English Gothic Salisbury Cathedral

Modern Concrete

Three types of pier used in architecture

bridges crossing rivers have to be constructed under water. Among the means employed in these situations are steel and iron cylinders, wells, caissons, bearing piles or some form of coffer-dam within which the foundations may be constructed. (*See* Caisson, Foundations, Coffer-dam.)

Piles are sometimes employed to provide both the foundations and the piers carrying a structure of viaduct character. Thus screw piles, having wide bearing-blades of cast-iron in the form of

a screw-thread turned about a central shaft or column of cast-iron or steel, are sometimes sunk through soft strata till they reach a firm bed, or one sufficiently consolidated by the superincumbent layers to enable it to support the weight imposed on the broad blades. Hollow, cast iron, cylindrical piles with a broad circular disc at the bottom to increase their bearing surface, have also been used for piers founded in sandy or silty strata of considerable thickness. They are sunk by hydraulic jetting, *i.e.*, the scouring away of the soft material from under the disc by means of a jet of water emitted under high pressure from a pipe lowered within the pile. Water jets are also employed to facilitate the sinking of screw and other forms of piles. (*See* FOUNDATIONS.)

Harbour Piers.—The term pier is often applied to works sheltering harbours such as the Tynemouth piers which are strictly breakwaters (*q.v.*). Landing stages also, whether solid or open, have for a long time been called piers, as the Admiralty pier and the Prince of Wales' pier at Dover, the former essentially a breakwater with provision for berthing vessels and landing passengers on its sheltered side. The jetties (*q.v.*) thrown out from the shore to protect the entrance to a river harbour are also sometimes described as piers. In North America the term is commonly employed for a wharf structure that projects into a river, fairway or harbour.

Promenade Piers.—Open promenade piers form a common feature at seaside resorts. Promenade piers are usually supported on open pile work of timber, cast iron or steel, but in recent years, reinforced concrete has been frequently employed both for the pile supports and superstructure. The open construction exposes little surface to waves or storms and does not interfere with the drift of shingle and sand along the coast. It is essential that the beams or girders carrying the deck of a promenade pier should be at an elevation well above the level of the crest of the highest wave. Timber piles are best suited for withstanding the shocks of vessels at landing stages, at which places they are generally used. In the case of reinforced-concrete landing stages, a falsework of timber is sometimes constructed in front of the main structure for this purpose. Screw piles are frequently used for promenade piers on sandy foreshores.

The pioneer of promenade piers in England was the old chain pier at Brighton, erected in 1822–3. It was founded on oak piles, was 1,136 ft. long and was destroyed by a gale in Dec. 1896. The length of promenade piers depends mainly on the distance from the shore at which sufficient depth is reached for steamers. Thus piers at Southend (Essex) and Southport (Lancs.) have been constructed across the wide sands in the estuaries of the Thames and Ribble respectively; the former over 1¼ m., the latter nearly a mile in length.

Works on bridge and other foundations are noted at the end of the article CAISSON. (N. G. G.)

In Architecture.—A pier in architecture is a vertical support carrying arches, a vault, a floor or a roof; especially one rectangular in plan; also, in mediaeval work, any support between the nave and aisles of a church. During the late Roman imperial period, pier design was carefully studied and in connection with such buildings as the basilicas, cross-shaped and other compound piers were developed to carry the cross arches and the groins or intersections of the vaulting. With the increasing use of vaulting for church naves and aisles, during the 11th and 12th centuries, pier design was still further developed. Although in England Norman piers are frequently great round columns, on the continent of Europe piers became common in which each arch or vaulting rib above was carried by a separate member of the pier. The earliest logical expression of this idea is found in Italian Lombard work, where a square pier has frequently an engaged column attached to each face; the one on the nave side carrying the cross-rib of the nave vault, that on the aisle side carrying the aisle vault cross-rib, and those on the other two sides carrying the pier arches between nave and aisles.

During the later Romanesque, pier plans were further complicated by the addition of smaller members to carry the subsidiary mouldings of the arches above, and larger members to carry the diagonal vaulting ribs. (*See* BYZANTINE AND ROMANESQUE ARCHITECTURE.) During the 13th and 14th centuries the piers of French Gothic churches were kept comparatively simple in plan, with great importance given to the capital at the level of the spring of the pier arch. Often it took the shape of a circular column with a few, large, simple attached vaulting shafts, as in Rheims cathedral (*c.* 1240). Toward the end of the 14th century, perhaps due to English influence, the column idea disappeared and was replaced by the more logical plan in which the pier was elaborately membered, not only by the additional development of vaulting shafts, but by breaking up the edges with projecting mouldings under the mouldings of the arches. Capitals became of less importance and vaulting shafts were carried unbroken through from floor to vault spring, capitals being placed merely on the separate mouldings of each arch or rib.

During the Flamboyant period this development was carried to its logical extreme; capitals were omitted entirely, and the pier plan became the combination of the various arch and vault rib mouldings continued down to the floor. Against this complexity a reaction was inevitable, and the other type of French Flamboyant pier developed, with smooth surface, either circular or wavy in plan, with the various vault rib and arch mouldings carried by the pier merely dying into it at their intersections. In England, during the Early English period, although circular piers are occasionally found, they were more frequently surrounded by entirely independent colonnettes, often of black Purbeck marble, which act as vaulting shafts and are tied to the body of the pier only at intervals by horizontal through stones with moulded edges. During the Decorated period attached shafts continued in use but the surfaces of the central core appearing between them were often richly moulded, and, in some cases, detached shafts disappeared entirely and the pier became a solid mass with surfaces lavishly moulded with strong projecting high lights and deeply cut shadows.

In the late Decorated period mouldings of the pier were sometimes the same as those of the arch above and capitals were omitted. This arrangement became much more frequent during the Perpendicular period. Pier-moulding profiles were softened and flattened like other mouldings of the period. (*See* GOTHIC ARCHITECTURE.) With the coming of the Renaissance pier design was much simplified, returning to the generally cross-shaped or twelve-cornered systems found in late Roman work, with all the projecting members treated either as classic imposts, engaged columns or pilasters.

Technically, the word pier is also applied to the solid portions of a wall between windows or other openings; and to the vertical posts at gateways, to which the gates are hung. The word pier is used of structures of timber or masonry projecting from a quay or sea wall and used either for loading and unloading ships, or in the case of summer resorts, for furnishing promenade space into the water. In America the word is loosely used synonymously with dock or landing stage.

PIERCE, FRANKLIN (1804–1869), fourteenth president of the United States, was born at Hillsboro, New Hampshire, Nov. 23, 1804. His father, Benjamin Pierce (1757–1839), served in the American army throughout the Revolutionary War, was a Democratic member of the New Hampshire house of representatives from 1789 to 1801, and was governor of the State in 1827. The son was prepared for college at Hancock, Francestown and Exeter academies and entered Bowdoin in 1820, where he formed a lifelong friendship with Nathaniel Hawthorne. After his graduation in 1824 he studied law and was admitted to the bar in 1827.

Entry into Politics.—Entering politics as a Democrat he became a member of the New Hampshire house of representatives in 1829, and was speaker of that body in 1831 and 1832. The following year he entered the national house of representatives. While he rarely spoke from the floor, he was an influential member of several committees, including the judiciary committee. A friend of President Jackson he supported administration policies. He adhered to a strict construction of the Federal Constitution, defended the Maysville veto, opposed the recharter of the bank of the United States, opposed appropriations to the U. S. military academy and favoured a volunteer army. During

his first term in Congress he married Jane Means Appleton, daughter of the president of Bowdoin college. In 1837 he entered the U.S. Senate. Being its youngest member, he was overshadowed by a galaxy of older and more prominent men such as Benton, Clay and Webster. Before his term expired he resigned his seat (1842) and returned to the practice of law at Concord, N.H., where he became Federal district attorney. In 1845 he was offered the Democratic nomination for governor of New Hampshire, also an appointment to fill an unexpired term in the U.S. Senate, and the next year the position of attorney-general in Polk's cabinet; but he rejected them all, declaring that he had permanently retired from political life.

Service in Mexican War.—Shortly after the outbreak of the war with Mexico in 1846 Pierce enlisted as a private at Concord, but soon became colonel of the 9th Regiment, and later a brigadier-general of volunteers. He was with Gen. Scott in the advance toward Mexico City. During the battle of Contreras he was thrown from his horse and received painful injuries. Despite the advice of Scott to the contrary he insisted on continuing the fight the next day and in the course of the battle he fainted. This fact, variously interpreted, was used both for and against him when he was later a candidate for the presidency. At the close of the war he returned to his law practice.

Election to Presidency.—Pierce became the Democratic nominee for president in 1852 "as a dark horse." Those in the foreground were Lewis Cass, Stephen A. Douglas and James Buchanan, but none of these proved to be available because of factional rivalries. A few politicians, foreseeing a deadlock, had prepared Pierce for the place. At the convention in Baltimore in June his name was first brought forward by the Virginia delegation on the 35th ballot, and on the 49th ballot he received an almost unanimous vote. Both the Democrats and the Whigs were too badly split for any real issues to appear in the campaign. The chief question in the public mind was the finality of the Compromise of 1850, and while both parties declared themselves in favour of it the Democrats were more thoroughly united in its support. As a result Pierce swept the country in the November election, receiving 254 electoral votes against 42 for his opponent, Gen. Winfield Scott.

Presidential Administration.—The youngest man to have been elevated to the presidency, Pierce was handsome, genial and possessed of a certain brilliance, which however was not profound. The Eastern element of the Democratic party which he directly represented was inclined for the sake of harmony and prosperity to oppose anti-slavery agitation and generally to placate Southern opinion. It was hence pro-Southern as a matter not only of political strategy but also of business expediency. Thus in the selection of his cabinet, as in both domestic and foreign policies of his administration, Pierce represented a coalition of Southern planters and Eastern business men. His cabinet included William L. Marcy of New York, secretary of state; Jefferson Davis of Mississippi, secretary of war; James Guthrie of Kentucky, secretary of the treasury; James C. Dobbin of North Carolina, secretary of the navy; Robert McClelland of Michigan, secretary of the interior; James Campbell of Pennsylvania, postmaster-general; and Caleb Cushing of Massachusetts, attorney-general. In his inaugural address Pierce interpreted his election as a popular mandate to maintain the Compromise of 1850 and bury the slavery controversy. He also forecast an aggressive, but honourable, foreign policy; he would "not be controlled by any timid forebodings of evil from expansion." In fact "the acquisition of certain possessions" (doubtless referring to Cuba in particular) was deemed essential to the country's safety and commerce.

Foreign Policy.—In accordance with the declarations of the inaugural Pierre Soulé, who had openly advocated the annexation of Cuba by means other than purchase if necessary, was appointed minister to Spain. When the Spanish Government showed its unwillingness to sell the island, Soulé, at the suggestion of secretary of State Marcy, held a conference with James Buchanan, minister to Great Britain, and John Y. Mason, minister to France, at Ostend, Belgium, as a result of which they issued the famous Ostend Manifesto. This was to the effect that if the United States were unable to obtain Cuba peacefully, "by every law, human and divine, we shall be justified in wresting it from Spain if we possess the power." In the storm of controversy which followed, the administration disclaimed responsibility for the document and recalled Soulé. The following year William Walker conducted a notorious filibustering expedition into Central America with the purpose of establishing a pro-slavery government to be brought under the control of the United States. He established himself as military dictator, then as president, of Nicaragua, and his regime was recognized by the Pierce administration. More fruitful of permanent results was the expedition sent out under Commodore Perry to Japan (1853) to induce her to open her doors to American trade. Lured by Yankee ingenuity and frightened by Western guns, she responded, and the result was the opening up of Japan. In the Koszta affair (1853) the government vigorously asserted the protection which it would offer those in the process of becoming its naturalized citizens. The administration also effected a reorganization of the diplomatic and consular service and the creation of the U.S. court of claims.

Domestic Policy.—Among the domestic policies of the Pierce administration were preparations for a transcontinental railroad and the opening up of the Northwest for settlement. It was in order to open the way for a southerly route to California through the lowest mountain passes that the Gadsden Purchase of 50,000 sq.m. of territory was acquired from Mexico in 1853 at a cost of $10,000,000. It was mainly to stimulate migration to the Northwest and facilitate the project of a central route to the Pacific that the Kansas-Nebraska bill was enacted in 1854, receiving the President's sanction. This opened two new territories for settlement with the slavery question to be settled in each by popular sovereignty. Thus the dread conflict was reawakened with the venom of incipient civil war. Pierce's administrative policies with reference to "bleeding Kansas" were pro-Southern. He thus lost much of his former support at the North and made himself unavailable as a candidate for a second term.

Save for a three years' tour in Europe, he lived at Concord, N.H., where he died on Oct. 8, 1869.

PIERO DI COSIMO (1462–1521), the name by which the Florentine painter Pietro di Lorenzo is generally known. He was born in Florence in 1462, and worked in the *bottega* of Cosimo Rosselli (from whom he derived his popular name). He had the gift of a fertile fantastic imagination, which, as a result of his journey to Rome in 1482 with Rosselli, became directed towards the myths of classic antiquity. In Rome he assisted his master with the frescoes in the Sistine chapel. He proves himself a true child of the Renaissance in such pictures as the "Death of Procris," at the National Gallery, the "Mars and Venus," at the Berlin Gallery, the "Perseus and Andromeda" series, at the Uffizi in Florence, and the "Hylas and the Nymphs," of the late Benson collection. The "Immaculate Conception," at the Uffizi, and the "Holy Family," at Dresden, are good examples of his religious pictures. Piero was distinguished for his landscapes and their cheerful accessories. The only known portraits that can be definitely ascribed to him are, at the National Gallery, the so-called "Bella Simonetta," at Chantilly, the portraits of Giuliano di San Gallo and his father, at The Hague, and a head of a youth, at Dulwich. Vasari related that Piero excelled in designing pageants and triumphal processions for the pleasure-loving youths of Florence. Piero di Cosimo exercised considerable influence upon his fellow pupils Albertinelli and Bartolommeo della Porta and was the master of Andrea del Sarto. Examples of his work are also to be found at the Louvre in Paris, the Liechtenstein collec-

tion in Vienna, the Borghese and Corsini Galleries in Rome, the Berlin Museum, the Spedale degli Innocenti in Florence, and in the collections of Burke in London and Cornwallis West in Newlands Manor.

PIERRE, the capital city of South Dakota, U.S.A., and the county seat of Hughes county; in the centre of the State, on the east bank of the Missouri river opposite the mouth of Bad river, at an altitude (at the State capitol) of 1,496 ft. It is on Federal highways 14 and 83; has a municipal airport; and is served by the Chicago and North Western railway. Pop. (1925 State census) 3,560. Four miles north of the city is a monument marking the geographical centre of the State and the approximate centre of North America. The State capitol (erected 1905–10) is a beautiful building 292 ft. long by 124 ft. wide and 161 ft. high to the top of the lantern. Near the capitol is an artificial lake, fed from an artesian well by water which never freezes, where swans, geese and wild ducks live the year round. The city owns more than a mile of river frontage, and its parks include a wooded island of 1,000 acres. Artesian wells supply the city not only with water but also with natural gas of high heating content. Pierre is the seat of a government Indian school and of Northern college (Christian; established 1927). The State Historical Museum (in the capitol) has many interesting relics, including a leaden plate, buried in 1743 by La Vérendrye on a hill across the river (within the present city of Fort Pierre) to claim the country for France, and discovered by high school children in 1913. Pierre is an important shipping point and centre of wholesale and jobbing interests. It has railroad shops, granite works and other manufacturing industries. The first permanent settlement by white men in South Dakota was made in 1817 by Joseph La Framboise, a fur trader, just below the mouth of Bad river. He called his post Ft. Teton. In 1822 Ft. Tecumseh was built 2 m. up-stream; and in 1832, when its site was washed into the river, Ft. Pierre Chouteau was erected to take its place, a mile farther up-stream and a little back from the river. It was named after Pierre Chouteau, Jr. (1789–1865), who had in 1804 succeeded his father in the Missouri Fur Company, and for 20 years Ft. Pierre (as it soon came to be called) was the chief fur-trading depot of the Upper Missouri country. In 1855 the United States bought the building and other property of the post and laid out around them a military reservation of 270 sq.m. (abandoned in 1857) which was the headquarters of operations against the Sioux and the scene of a council with their chiefs. In the early days steamboats plied regularly on the Missouri river as far as Ft. Benton (Montana) 1,000 m. above Pierre. The first sermon in South Dakota was preached in 1840 by the Rev. Stephen R. Riggs, a missionary to the Dakota Indians, on a spot near the free wagon bridge across the Missouri which bears his name. The city was platted in 1880, incorporated as a village in 1883, and chartered as a city in 1900. One of the few surviving herds of buffalo in the United States is quartered in the river brakes 4 m. north of Fort Pierre.

PIERREFONDS, a town of northern France, in the department of Oise, 9 m. S.E. of Compiègne by road. Pop. (1926) 1,097. Pierrefonds has an 11th to 16th century church, and its mineral springs are in some repute. The famous château was begun in the late 14th century by Louis d'Orléans, to whom the domain was given by Charles VI., and finished early in the 15th century. It was later held by the Burgundians, the English and the adherents of the League, from whom it passed to Henry IV. It was dismantled in 1622. The ruins, bought by Napoleon I., were faithfully restored, by order of Napoleon III., in 1858–95, under the direction, first of Viollet-le-Duc and afterwards of E. Boeswillwald. The building is rectangular in shape, with a tower at each corner and at the centre of each of the walls. A lofty keep defends the principal entrances on the south-west.

PIERROT [Ital. *Pedrolino*], the name given to the leading character in the French pantomime plays since the 18th century; transferred from the Italian stage, and revived especially in recent times. He is always in white, both face and costume, with a loose and daintily clownish garb, and is represented as of a freakish disposition. Modern pierrot plays have converted the pierrot into a romantic and pathetic figure. (*See* PANTOMIME.)

PIETAS, in Roman mythology, the personification of the sense of duty towards God and man and towards the fatherland. According to legend, a young woman in humble circumstances, whose father (or mother) was lying in prison under sentence of death, without food, managed to gain admittance, and fed her parent with milk from her breast. To commemorate her filial affection, a temple was dedicated (181 B.C.) by Manius Acilius Glabrio to Pietas in the Forum Holitorium at Rome, on the spot where the young woman had formerly lived. The temple was probably originally vowed by the elder Glabrio out of gratitude for the *pietas* shown during the engagement by his son, who may have saved his life, as did the elder Africanus that of his father at the battle of Ticinus (Livy xxi. 46); the legend of the young woman (borrowed from the Greek story of Mycon and Pero, Val. Max. v. 4, ext. 1) was then connected with the temple by the identification of its site with that of the prison. Pietas is shown on coins as a matron throwing incense on an altar, her attribute being a stork. Typical examples of "piety" are Aeneas, and Antoninus Pius, who founded games at Puteoli in honour of Hadrian.

PIETERMARITZBURG, the capital of Natal, South Africa, 29° 46′ S., 30° 13′ E.; altitude 2,218 feet. Though only 41 m. inland, it is 73 m. by rail from the port of Durban. The main town is laid out on a low ridge between the Umsundusi River and the Dorp Spruit. Suburbs have grown up on two other ridges across the river to the south-east of the town, and also on the slopes of a marked escarpment, which rises over 1,500 ft. above the town on the north-west side. The low ground between the ridges is occupied either by Indian dwellings and cultivation, or by open spaces, laid out as public parks and sports grounds, with which the city is very well provided. On the west of the town are the botanical gardens. There are memorials of the Zulu, South African and World Wars. The town was founded in 1839 by Dutch immigrants and connected by railway with Durban in 1880.

Among the public buildings are the town hall, containing a remarkably fine organ and a good collection of pictures, the Provincial Council building, the Colonial offices, the Court house, the post office and the museum, which has an exceedingly good collection of the South African fauna. The Voortrekkers' museum is housed in what used to be a Dutch church. The Natal Society library is also admirable. The city is the seat of an Anglican bishop. It is noted for its agricultural show, held every June. There is a large number of high schools for day pupils and boarders, both in the city and outside. In addition there is a training college and a university college, a constituent of the University of South Africa. Means of locomotion are provided by a tramway system, jinrikshas, and motor cars. In 1921 the population included 9,992 natives, 6,944 Asiatics, 1,089 coloured people and 17,998 Europeans. The latter had increased by 1926 to 19,748.

PIETERSBURG, chief town of the Pietersburg district of the Transvaal, 177 m. by rail N.N.E. of Pretoria: altitude, 4,269 ft. Pop. (1921) 2,452 whites, 3,325 natives, 183 Asiatics and 103 coloured: total 6,063. The surrounding country contains minerals. To the east are the Klein Letaba and other low country goldfields; to the west are the Waterberg goldfields. Asbestos, tin and corundum also occur, the latter being exported in fair quantity. Cereals, tobacco, cotton and groundnuts are cultivated and towards the east, citrus estates have developed.

PIETERS HILL, 10 miles S.S.E. of Ladysmith, has given its name to the fourth and finally successful British attempt to relieve Ladysmith at the end of Feb. 1900 (*see* LADYSMITH and SOUTH AFRICAN WAR). Buller, having tried a frontal attack and two attacks on the right of the Boer lines, now resolved to assail their left, and the operations opened with the successful storming of their positions on the south bank of the Tugela east of Colenso, which fell into British hands after six days of methodical

fighting. Thereafter Buller drew back the bulk of his force to the north bank, its next objective being the group of hills immediately north of Colenso. On Feb. 27, the British right wing captured Pieters Hill, the northern buttress of the ridge, and next day Buller's cavalry entered Ladysmith, which had stood a four months' siege.

PIETISM, a movement in the Lutheran Church, which arose towards the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement as a term of ridicule, like that of "Methodists" somewhat later in England. The Lutheran Church had continued Melanchthon's attempt to construct the evangelical faith as a doctrinal system; and it appeared to many faithful adherents to have become a creed-bound theological and sacramentarian institution, where the dogmatic formularies of the Church had usurped the position which Luther himself had assigned to the Bible alone. The influence of the Reformed Church (*q.v.*) on the other hand, in spite of the predestinarianism of Calvin, made less for doctrine than the practical formation of Christian life. The Presbyterian constitution gave the people a share in church life which the Lutherans lacked, but it involved a dogmatic legalism which imperilled Christian freedom and fostered self-righteousness.

The direct originator of the movement for the revival of a practical and devout Christianity was Philip Jacob Spener, who combined the Lutheran emphasis on Biblical doctrine with the Reformed tendency to vigorous Christian life. Born at Rappoltsweiler in Alsace on the 13th of January 1635, trained by a devout godmother, who used books of devotion like Arndt's *True Christianity*, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, Spener was early convinced of the necessity of a moral and religious reformation of the German Church. He studied theology, with a view to the Christian ministry, at Strassburg and entered upon his first pastoral charge at Frankfort-on-the-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a distinct movement in the German Church, was then originated by Spener by religious meetings at his house (*collegia pietatis*), at which he repeated his sermons, expounded passages of the New Testament, and induced those present to join in conversation on religious questions that arose. They gave rise to the name "Pietists." In 1675 Spener published his *Pia desideria*, or *Earnest Desires for a Reform of the True Evangelical Church*. In this publication he made six proposals as the best means of restoring the life of the Church: (1) the earnest and thorough study of the Bible in private meetings, *ecclesiolae in ecclesia;* (2) the Christian priesthood being universal, the laity should share in the spiritual government of the Church; (3) a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) instead of merely didactic, and often bitter, attacks on the heterodox and unbelievers, a sympathetic and kindly treatment of them; (5) a reorganization of the theological training of the universities, giving more prominence to the devotional life; and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany, and although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by Spener's book, its complaints and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In Paul Gerhardt the movement found a singer whose hymns are genuine folk poetry. In 1686 Spener accepted an appointment to the court-chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. One of his most enthusiastic disciples was August Hermann Francke, who had founded the famous orphanage at Halle, and with the aid of Christian Thomasius and Spener founded the new university there. The theological chairs were filled in conformity with Spener's proposals. Spener died in 1705; but the movement, guided by Francke, spread over Middle and North Germany. One of its greatest achievements was the organization of the Moravian Church in 1727 by Count von Zinzendorf, Spener's godson and a pupil in the Halle Orphanage.

Pietism, of course, had its weaknesses. Many Pietists maintained that the new birth must always be preceded by agonies of repentance, and that only a regenerated theologian could teach theology, while the whole school shunned all common worldly amusements, such as dancing, the theatre, and public games. There thus arose a new form of justification by works.

As a distinct movement Pietism had run its course before the middle of the 18th century; by its very individualism it had helped to prepare the way for another great movement, the Illumination (*Aufklärung*).

PIETRO DELLA VIGNA or **PIER DELLE VIGNE** [Petrus de Vineas or de Vineis] (*c.* 1190–1249), chancellor and secretary to the emperor Frederick II., born at Capua in humble circumstances, studied law at Padua. He became secretary to Frederick II., who made him *judex magnae curiae*, councillor, governor of Apulia, prothonotary and chancellor. The emperor, "of whose heart he held the keys," as Dante says, sent him to Rome in 1232 and 1237 to negotiate with the pope, to Padua in 1239 to induce the citizens to accept imperial protection, to England in 1234–35 to arrange a marriage between Frederick and Isabella, sister of King Henry III. He proved a skilful and trustworthy diplomat, and he persistently defended the emperor against his traducers and against the pope's menaces. At the Council of Lyons Pietro della Vigna entrusted the defence of his master to the jurist Taddeo of Suessa, who failed to prevent his condemnation. Frederick had his chancellor imprisoned and blinded without giving him a chance to rebut his accusers. He is said to have committed suicide in his prison at Pisa in 1249. His tragic fate gave rise to many legends.

Pietro della Vigna wrote verse in the vernacular tongue, of which two *canzoni* and a sonnet are extant. His letters (*Epistolarum libri vi.*, 2 vols., Basel, 1740), are of historical value. A collection of the laws of Sicily, a *Tractatus de potestate imperiali*, and another treatise, "On Consolation," in the style of Boëthius, are also attributed to him.

PIG (a word of obscure origin, connected with the Low Ger. and Dut. word of the same meaning, *bigge*), a common name given to the domestic swine. (For the zoology, *see* Swine.)

British Breeds.—Twelve breeds are recognised in Britain:—

The *Large White* or large Yorkshire is a breed which has been evolved in the north of England and is now very wide-spread and important. The animals are large, long and deep and when young, even if heavily fed, do not readily become too fat. The head is long, light in the jowl, and wide between the eyes, with long thin ears inclined slightly forward and fringed with long fine hair. The neck is long, but not coarse, the ribs are deep, the loin wide and level, the tail set high, and the legs straight and set well outside the carcass. The whole body, including the back of the neck, is covered with straight silky hair, which denotes quality and lean meat. Pigs of this breed are very prolific, and they may be grown to enormous weights—over 11 cwt. alive.

The *Middle White* is considered to have been produced by crossing the Large White and the now extinct Small White. The latter was a small early maturing and excessively fat type of pig. The Middle Whites are built on a smaller scale than the Large Whites. They are shorter in the heads and legs, and fuller at the jowl, thicker and more compact in the body. The sows are not quite as prolific as those of the Large White breed, but, as their

produce matures earlier, they are much in demand for breeding porkers. If fed to heavy weights the animals become too fat.

The *Lincolnshire Curly Coated* or *Boston* pig is a local breed of great size and capacity for producing pork. It is very hardy and prolific, but somewhat coarse in the bone. It has an abundance of long curly hair, a short face and a straight nose, and the ears, not too long and heavy, fall over the face. It crosses well with the Large White, the Large Black and the Berkshire.

The *Large Black* breed, which vies with the Large White breed for size, has only since 1900 received national show-yard recognition; but there is ample evidence that, with its characteristic whole black colour with a mealy hue, length, fine hair and lop ear, the Large Black existed in the south of England for generations. It has been continuously and carefully bred in Cornwall, Devon, Essex and Suffolk, and from these centres it has rapidly spread all over the country. Large Blacks are exceedingly docile, and the ears, hanging well forward over the eyes, contribute materially to a quietness of habit which renders them peculiarly adapted to field grazing. On account of their hardiness and disposition to early maturity they have proved valuable for crossing. The Large Black Pig Society was incorporated in 1899.

The *Berkshire* is a black pig with a pinkish skin, and a little white on the face, pasterns, and tip of the tail. It has a moderately short head with a deep, compact carcass, and wide, low and well-developed hind-quarters, with heavy hams. The skin carries an abundance of fine hair. The Berkshire is an early-maturity breed which has been somewhat inbred, and is not so hardy and prolific as most breeds. The boars cross well with common stock. The breed produces meat of outstanding quality and is extremely difficult to beat in carcass competitions; it does best when fed for the pork market.

The *Tamworth* is one of the oldest breeds of pigs and is considered to be directly descended from the wild native pig. The colour is red or chestnut. The head, body and legs are long, and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred, and highly valued as a bacon pig.

The *Cumberland* is a pig of the Large White type. It is, however, shorter and thicker in form; it has a dished face and drooping ears. The hair is fine and sparse. The breed fattens readily and the pork is of good quality.

The *Long White Lop-Eared* was formed by amalgamating the Old Glamorgan and Welsh breeds, which were of a similar type. The general conformation is very similar to that of the Large Black. The animals are hardy and they do well in the open air.

The *Large White Ulster* is of the Large White type but compared with that breed it is shorter in the body, finer in the hair, thinner in the skin and possesses drooping ears. It is very suitable for the bacon trade and is kept in Ulster practically to the exclusion of all other breeds.

The *Gloucestershire Old Spots* is an old local type which was constituted as a pure breed in 1914. The breed is rather thicker in form than is the Large White. The colour is black and white in fairly large clearly defined spots. The head is of medium length; the ears are long and drooping. The animals are hardy and they are very suitable for the heavy pork trade.

The *Wessex Saddleback* and the *Essex* are two breeds of very similar conformation and colour markings. The colour is black with a white "saddle" and white fore-legs. The Essex also has white on the hind legs, the tail and the nose. The animals are of medium size and are considered to be hardy.

Management.—The brood sow should be lengthy and of a prolific strain, known to milk well. She is moderately fed and put to a boar of her own age when large enough, *i.e.*, seven to eight months old. She remains in a state of oestrum for about three days, and if not pregnant comes in heat again in three weeks. Breeding swine, male and female, run most of their time at pasture and receive a liberal allowance of green food or raw roots. The period of gestation is sixteen weeks. Six to eight pigs are reared of the first litter, and ten to twelve afterwards. Many brood sows are fattened to greatest profit after the second or third litter, but on the other hand the animals may be kept as long as they are satisfactory breeders. Two litters are produced in one year, as pigs are usually weaned at two months old, and the sow will take the boar at from three days to a week after the pigs are removed, according to condition.

The digestive system of the pig is not fitted to deal with fibrous or bulky fodders and the food should be highly concentrated. In practice pigs are fed largely on dairy by-products such as whey and separated milk, milling offals, cereal meals, waste potatoes and kitchen scraps. Pigs do well on mixtures of milk products and cereal meals or offals. If no milk or whey is available the meals or potatoes should be balanced with 10% of white fish meal or meat meal or other foodstuff rich in albuminoids. Kitchen scraps should be cooked and the fat skimmed off before being given to pigs. Potatoes are best fed in a cooked condition. Chalk and other mineral matter are often added.

Every endeavour should be made to provide young pigs with some milk or milk product for a time after weaning. Fattening pigs should be given from ⅕ to ¼ lb. of mixed cereal meals, or their equivalent of other foods, for every week of age. Thus at 12 weeks the pig should get about 2½ lb. of dry meal or its equivalent per day; at 20 weeks, about 4½ lb.; at 30 weeks, about 7½ lb. Another rough rule is to give 1 lb. of meal for every 25 lb. live weight. With dry food, water will of course have to be available. Sows in pig require about 5 lb. of meal or its equivalent per day; sows in milk need 10 or 12 lb. It is usual to spread the ration over three meals per day.

Porker pigs are frequently slaughtered when about 4½ months old and 100 lb. live weight; they yield about 65 lb. of dressed carcass. Many pigs are, however, marketed for pork at much greater weights. A typical bacon pig should weigh about 220 lb. live weight or 165 lb. carcass weight and should be ready for slaughter when 7–8 months old.

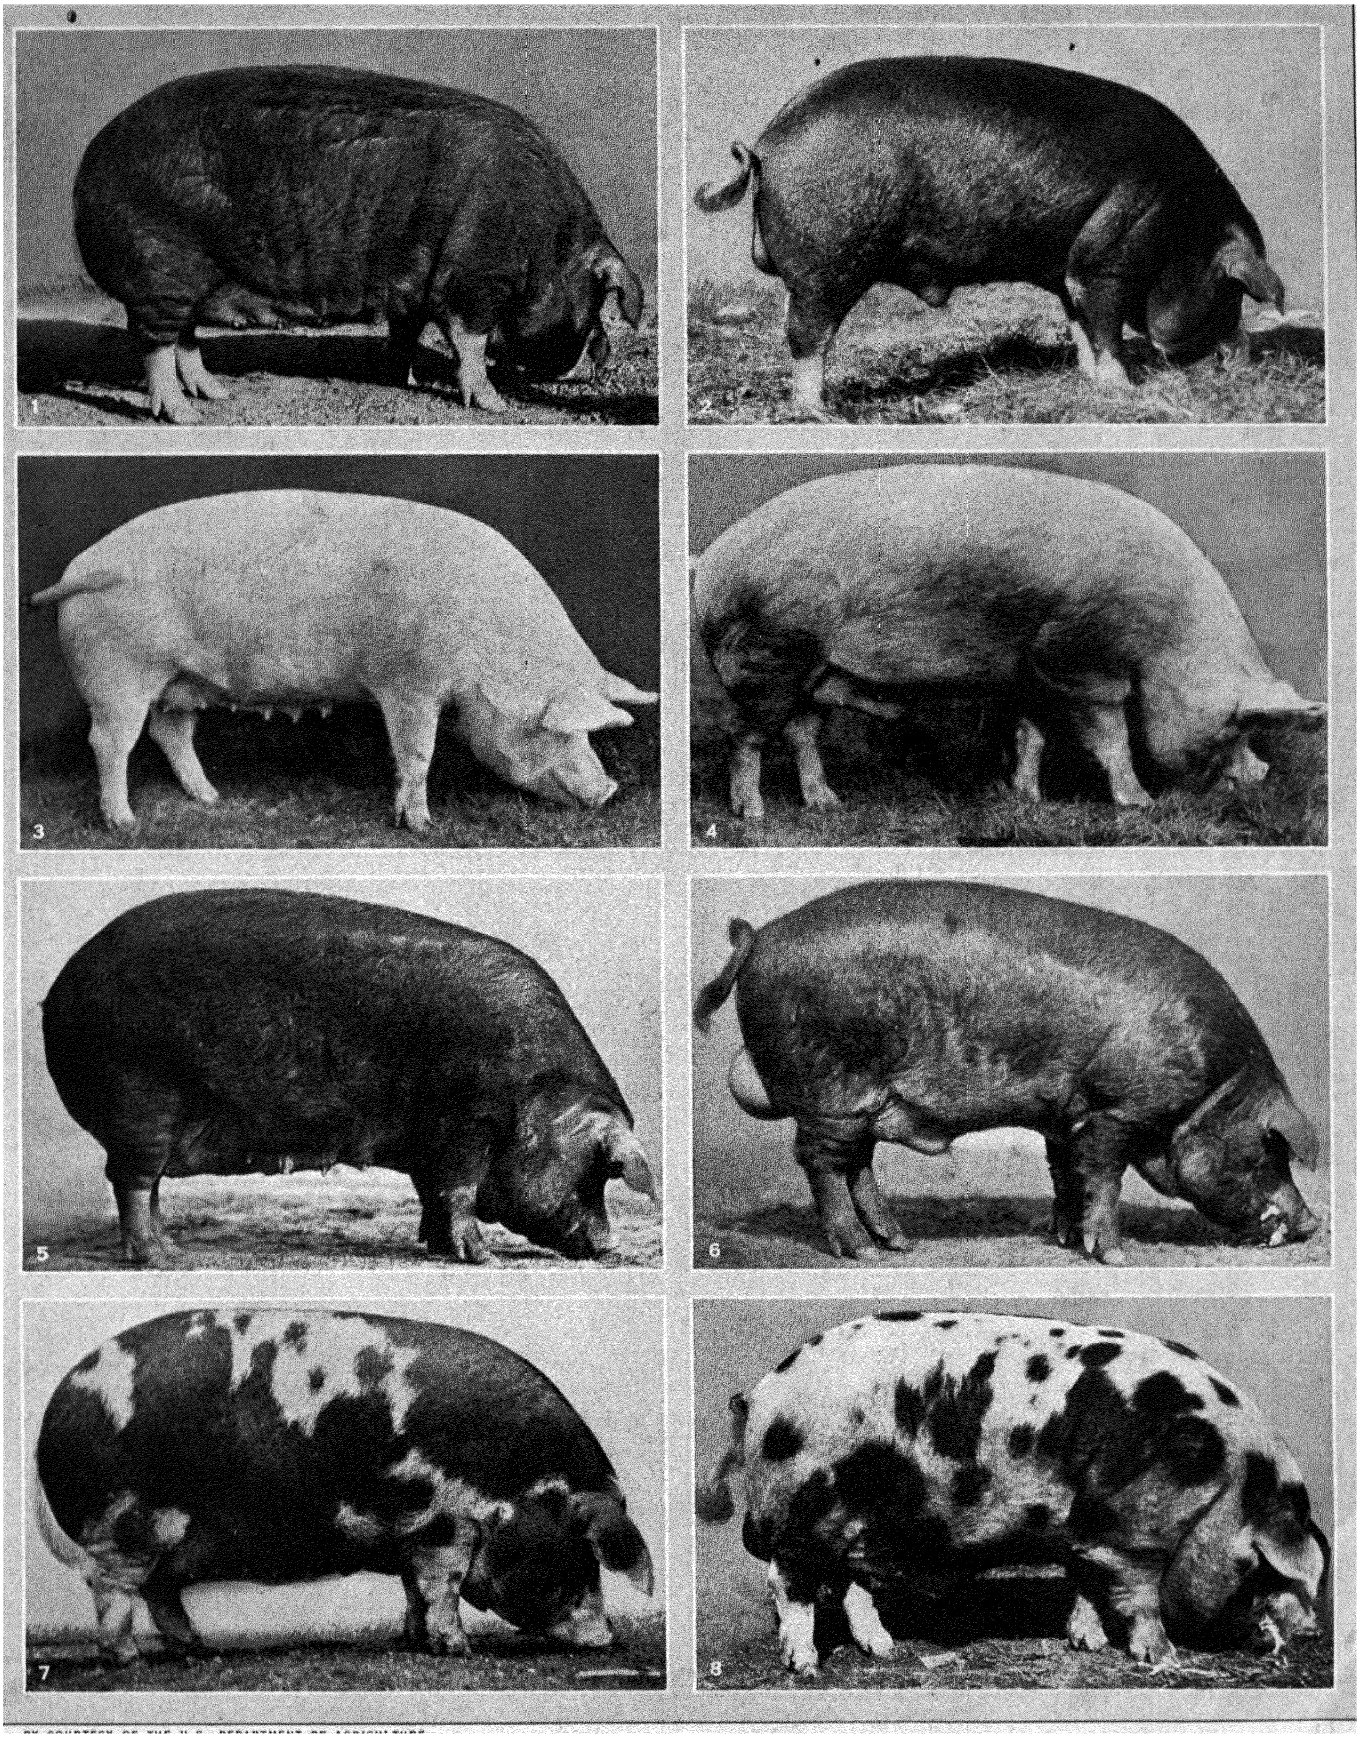
(R. WA.; J. A. MO.)

The United States.—The *Poland China* breed originated in Ohio, principally in the counties of Butler and Warren. The foundation stock consisted of so-called Bedford, Woburn, Russian and Irish Grazier hogs, improved by an introduction of Berkshire blood. The breed was at first white and black spotted, but later the black body with white at the face, feet and tip of tail, became the standard colour. The breed is large in size, boars commonly weighing 1,000 lb., while sows at maturity often weigh as high as 800 lb. Lengthy proportions, combined with height, ruggedness of bone, and meat producing qualities, are especially stressed in this breed. The head of the Poland China is rugged in appearance, medium in length and slightly dished in the profile. The ear is rigid from the point of attachment on the head to approximately one-half to two-thirds of its length, with the tip one-half or one-third broken over. In body conformation, the Poland China is long, deep and tall. The shoulders are smooth and compact, and the back is evenly and smoothly arched. This breed is found in all parts of the United States, as well as in many other countries.

The *Duroc-Jersey* originated in the eastern part of the United States, mainly in New York and New Jersey. The foundation stock, it is thought, came from Africa, Portugal and Spain. In general, the conformation of the Duroc-Jersey resembles that of the Poland China. However, the head is smaller and more refined, and the back is somewhat more evenly arched. In colour this breed ranges from a light golden yellow to what approximates a mahogany brown. The ideal colour, however, is a deep golden yellow inclining to a cherry red.

The *Chester White* originated in Chester county, Pa. The foundation stock consisted of native stock combined with English hogs, particularly the Large Yorkshire. Individual breeders have at various times attempted to establish other breeds similar in character and breeding to the Chester White. A notable example of this is the so-called O.I.C., which means the Ohio Improved



VARIOUS BREEDS OF PIGS

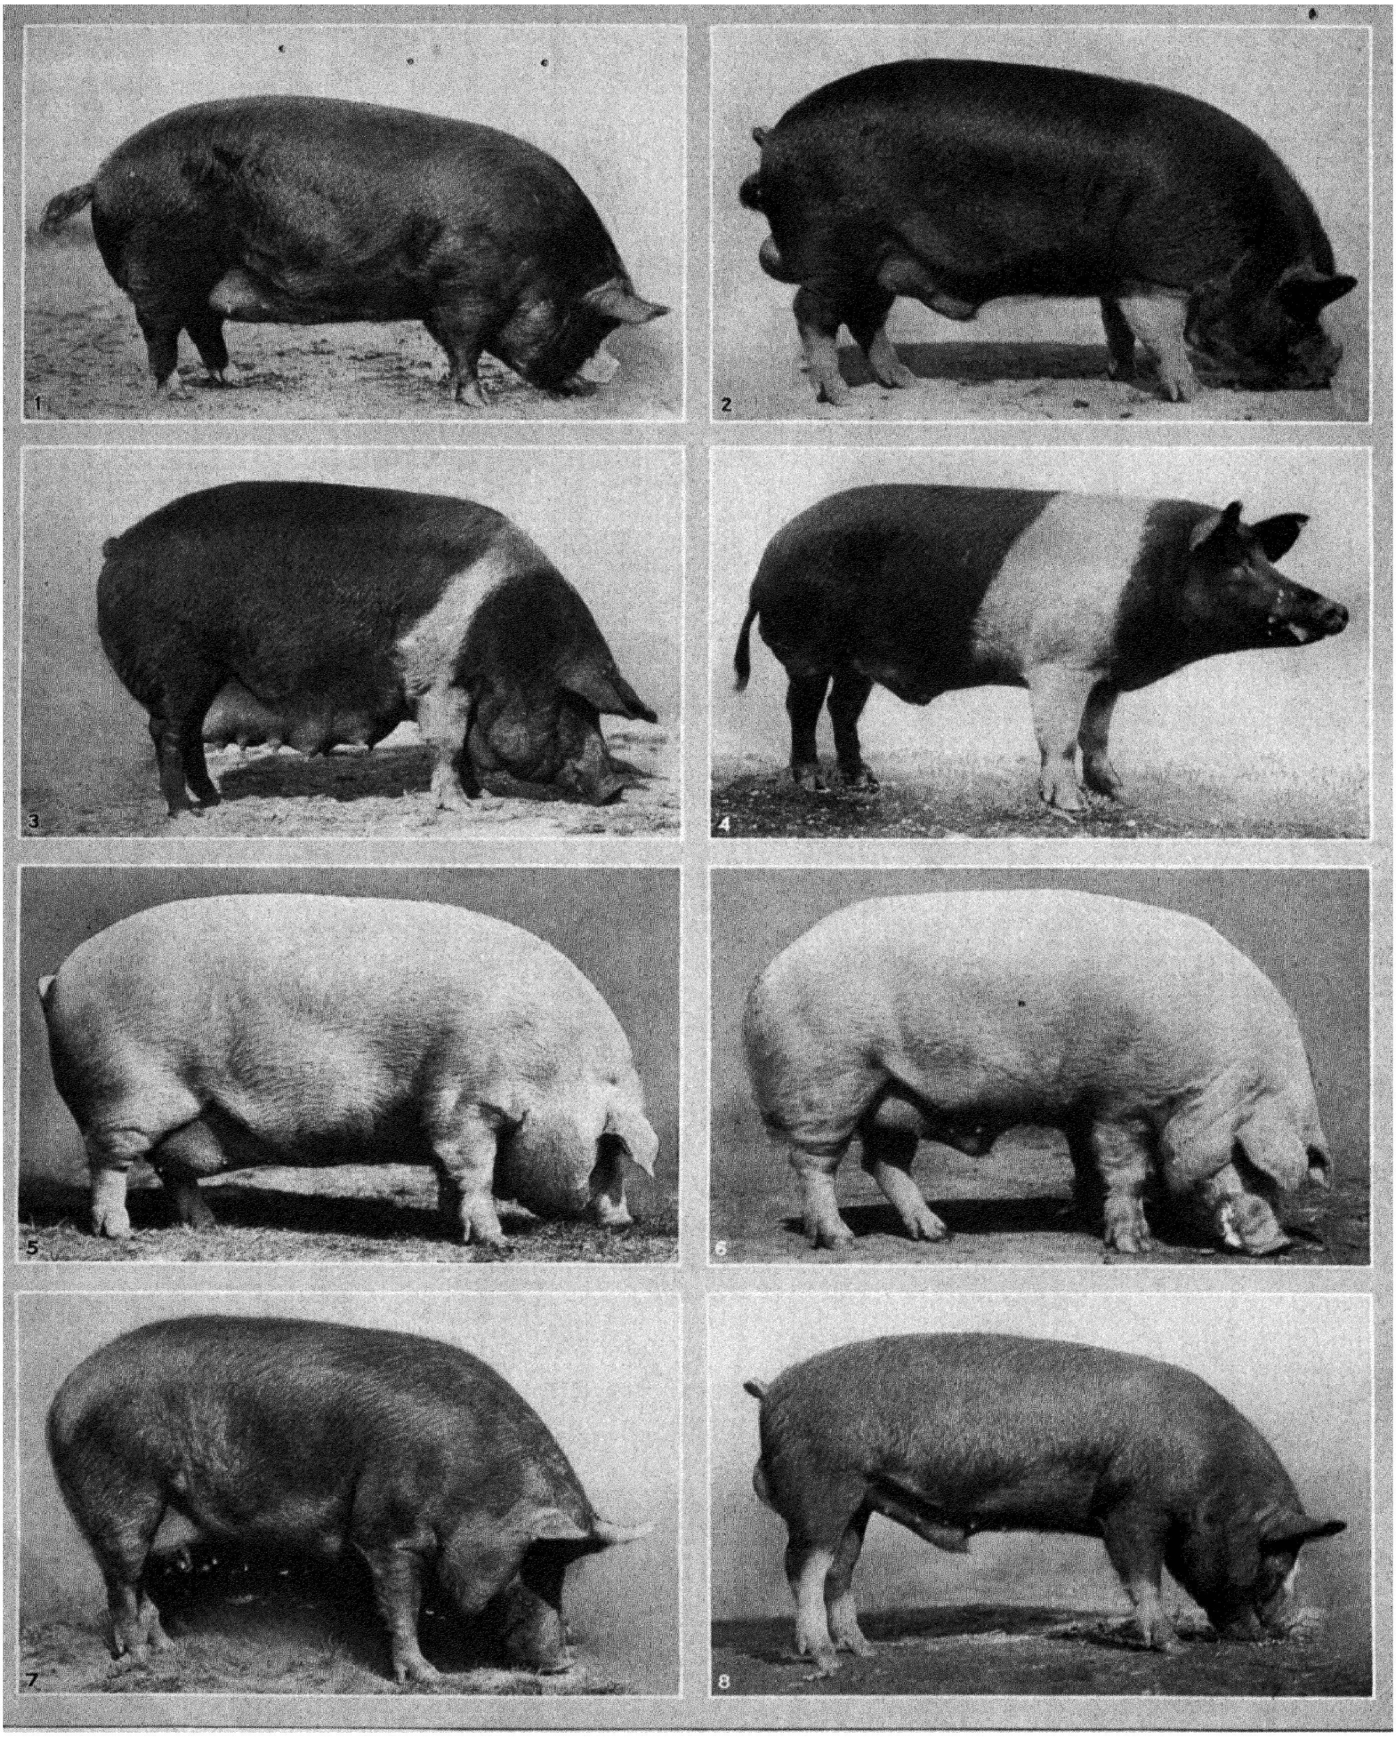
6. Duroc-Jersey. Boar
7. Spotted Poland China. Sow
8. Spotted Poland China. Boar

PIG



BREEDS OF PIGS

1. Berkshire sow
2. Berkshire boar
3. Hampshire sow
4. Hampshire boar
5. Chester White sow
6. Chester White boar
7. Tamworth sow
8. Tamworth boar

Chester White. This latter so-called breed is organized into a breed association, and the breeders record their animals separately from the Chester White. There seems to be little to distinguish one breed from the other. The Chester White is pure white in colour, although black or bluish spots known as freckles are frequently found on the hide. In size the Chester White does not quite rank with the Poland China or the Duroc-Jersey. Boars at maturity, however, often weigh 900 lb., while the females commonly reach a weight of 700 lb. A medium sized head and ear, clean, trim jowls, and an evenly turned back, are characteristic of the Chester White. Like the Poland China and Duroc-Jersey, one-half to one-third of the tip end of the ear is broken over. This breed is quite popular in the corn belt, but due to its white colour does not stand the sun as well as a dark coloured breed

The *Hampshire* breed, while a native of America, originated from English stock, probably the Wessex Saddle Back and the Essex. In colour markings the American Hampshire resembles these breeds The Hampshire has had its greatest improvement in Ohio, Illinois, Iowa and other corn belt States. The breed has gained its popularity through its fecundity, foraging properties and its ability to yield a high grade carcass. Among the common lard breeds in America the Hampshire is relatively small. It is extremely trim in its lines, is especially clean cut about its head, and is smooth and firm in its bone. The face of the Hampshire is straight in profile and the ears are rigid from point of attachment at the head to the tip end. The promoters of this breed discriminate against heavy jowls, dished faces and any tendency toward roughness.

The *Berkshire* breed is a native of England but has received considerable attention in America. It is classed as a lard breed and has been especially noteworthy because of the high quality of carcass it produces. The Berkshire has the same colour marking as the Poland China but is not so large in size The ears are rigid and the face is dished

The *Tamworth* and *Large Yorkshire* are the two most common bacon breeds in America Both these breeds received their origin in England and are similar in body conformation. They differ, however, in colour The Large Yorkshire is white, while the Tamworth is red, similar to the Duroc-Jersey in this respect. The bacon breeds less popular than the lard breeds (J. S C)

PIGEON, a name of Norman introduction for certain birds of the family Columbae (*see* DOVE). Perhaps the best known species to which the name is exclusively applied is the passenger pigeon (*Ectopistes migrarius*) of North America Formerly nesting in countless multitudes in the then "backwoods" of Kentucky, Ohio, and Indiana, this bird is now extinct, the last specimen dying in Cincinnati Zoological Gardens in 1914 The passenger pigeon was about the size of a turtle-dove, but with a long, wedge-shaped tail The male was a dark slate colour above and purplish-bay below; the female, drab above, dull white beneath. The beautiful fruit-pigeons (*Treron*) of tropical Africa, India, and the Malay Archipelago are, perhaps, the most delicately flavoured of all birds.

The largest forms are the giant crowned pigeons (*Goura*) of New Guinea; they have a beautiful filmy, fan-shaped crest on the head. The Nicobar pigeon (*Caloenas*) is remarkable for the long lustrous neck hackles and its peculiar gizzard

Pigeons lay two or three white eggs and the naked, helpless young are fed by a secretion from their parents' crops ("pigeon milk").

PIGEON-FLYING, the sport of racing homing-pigeons bred and trained for the purpose. It is of very recent date, although the use of birds as a means of carrying messages (*see* PIGEON POST) is of great antiquity. Belgium may be considered as *par excellence* the home of the sport, the first birds flown there probably coming from Holland Long distance flying began in 1818, with a match of 100m., while in 1820 there was a race from Paris to Liége, and in 1823 from London to Belgium. The Belgian *concours national*, a race of about 500m. from Toulouse to Brussels, was inaugurated in 1881, in which year the first regular races in Great Britain took place.

The sport was introduced into the United States about the year 1875, although regular racing did not begin until 1878. Since then it has gained widespread popularity. The speed depends very greatly upon the state of the atmosphere. In the race from Montargis to Brussels in 1876 in bright and clear weather, all the prize-winners made the distance of 270m. within 3½ hours, while in the same race in 1877, on a thick and stormy day, 30 hours passed before the first bird arrived

Training.—The loft should be on a commanding site. It is best made in the shape of a large room, suitably subdivided, protected from vermin, and provided with drinking troughs, rock salt and crushed mortar for the birds' use It should be fitted with a sufficient number of nests about 2ft. long, 20in. in breadth and height Arrangements should be made for allowing the pigeons to fly out daily for exercise; and they should be trained to re-enter the loft through bolting wires, which open inwards only, into a small chamber, to which an electric arrangement may be fitted so as to sound a bell and warn the owner of the arrival of a bird The food of birds in training consists of vetch, beans, maize, peas, broken rice and millet, in various proportions according to the country, climate and season of the year, the daily allowance for each bird being about 40 grammes weight.

Training should commence in warm weather, when the bird is about four months old, and consists in taking it out in a closed wicker basket and liberating or "tossing" it at gradually increasing distances from its loft, with several days interval of rest between the flights. The usual preliminary distances are, 1, 2, 5, 10 and 15 or 20m These tosses should all be made on the same line between the loft and, say, some neighbouring city, in order that a bird may always have to fly in the same general direction during the season. About 100m. may be expected of birds the first season; they do not reach their full distances until about the fifth year. The Belgian fanciers generally divide their birds into two classes, one for breeding and the other for racing though the latter are allowed to breed within certain limits Some fanciers always choose birds with chicks in the nest for long journeys, claiming that they return faster with this incentive. A seamless metal ring marked with the owner's name is slipped over the foot of the pigeon when only a few days old, and during its racing career the longer wing-feathers are stamped with the bird's records At the start of a race the competing birds are tossed together by a starter who takes the time Upon being released the homer ascends rapidly in spirals until, apparently descrying some familiar landmark on the horizon, it will fly straight and swiftly towards it. As the birds enter their home lofts the time is taken by the owner. A bird is not considered to have got "home" until actually through the door of its loft.

PIGEON POST. The use of homing pigeons to carry messages is as old as Solomon, and the ancient Greeks, to whom the art of training the birds came probably from the Persians, conveyed the names of Olympic victors to their various cities by this means Before the electric telegraph this method of communication had a considerable vogue amongst stockbrokers and financiers The Dutch Government established a civil and military pigeon system in Java and Sumatra early in the 19th century, the birds being obtained from Baghdad. Pigeons were employed during the siege of Paris in 1870–71 This led to a revival in the training of pigeons for military and naval purposes They have also been used by newspapers for reporting It has been found very important to establish registration of all birds In order to hinder the efficiency of the systems of foreign countries, difficulties were placed in the way of the importation of their birds for training, and in a few cases falcons were specially trained to interrupt the service in war-time, the Germans having set the example by employing hawks against the Paris pigeons in 1870–71. No satisfactory method of protecting the weaker birds seems to have been evolved, though the Chinese formerly provided their pigeons with whistles and bells to scare away birds of prey

During the World War pigeons were frequently used to bring back messages from advanced positions and often rendered very valuable service, but the development of wireless telegraphy will restrict their uses.

See L. du Puy de Podio, *Die Brieftaube in der Kriegskunst* (Leipzig

1872); Brinckmeier, *Anzucht, Pflege, und Dressur der Brieftauben* (Ilmenau, 1891).

PIG IRON. Crude cast iron, run from the blast furnace directly into moulds. The moulds originally were of sand formed in a way which suggested a nursing litter of pigs. (*See* IRON AND STEEL MANUFACTURE; BLAST FURNACE.)

PIGMENTS: *see* PAINTS, CHEMISTRY OF.

PIGMENTS OF SKIN AND HAIR. The pigment of the skin, the pigment of the blood, the pigment of the yolk of the egg, and the pigment of the butterfly's wing may each be regarded as representative of a chemical group of colouring matters, and into those four groups the great bulk of the pigments seen in the animal world may be placed.

The Pigment of the Skin.—The skin consists of two principal layers—the epidermis or superficial portion, and the dermis or deep portion. The dermis is not pigmented in man, nor is the epidermis in the so-called white races. In the negro the epidermis is densely pigmented, the pigment being present in granules. These granules are not uniformly distributed throughout the epidermis, which itself consists of many layers of cells, but they are confined to the layer of cells next to the dermis, and, therefore, farthest removed from the external surface.

The black pigment of the skin, which is called melanin, is situated in granules in the deepest layer of endo-dermal cells, namely, that placed immediately over the dermis. All the cells of the epidermis really are developed from this layer (the Malpighian layer) the constituents of which divide and work their way towards the surface. It might be supposed that all the epidermal cells should there be pigmented, but this is not so; as they get nearer the surface, they lose their pigment. This is well shown in the case of a blister. The fluid forms in the epidermis, separating the deeper from the more superficial portion; the covering of the blister in a negro is not pigmented.

In man the pigment is present as a quite inert deposit, the person being no more negroid at one time than another; but in many lower animals this is not so. The frog, for instance, will at one time be dark, at another pale. The melanin in the frog's skin is laid down in special cells known as melanophores; these may contract in minute balls, in which case the skin is pale, or they may expand, pushing out branches in all directions, in which case they form an almost continuous network of pigmented material.

The degree of expansion of the melanophores is regulated by circumstances, the following table being given by Hogben (abbreviated):—

Normal Responses of Common Frog

Background	20° C	10° C
Light:		
(*a*) Dry	Pallor	Generally pale
(*b*) Moist	Pallor	Darkening
Shaded or dark:		
(*a*) Dry	Pallor	Partial darkening
(*b*) Moist	Darkening	Darkening
Darkness:		
(*a*) Dry	Pallor	Partial darkening
(*b*) Moist	Darkening	Darkening

Evidently their dark background, low temperature and moistness tend to make the melanophores expand. The mechanism by which expansion of the melanophores in the frog is effected is bound up with a remarkable body situated underneath, and connected with the brain—the pituitary body (*see* art. HORMONES). This body secretes, no doubt at the bidding of the brain, a hormone into the blood which, acting on the melanophores, causes them to expand.

The pigment cells in the frog, unlike those in man, are situated at different levels; some are in the epidermis and some in the dermis. This arrangement has been exploited very completely by the chameleon. The chameleon possesses two layers of cells, each in the dermis. As an example may be taken an animal which alters in colour from a yellow or very pale green, through green to something nearly black. The cells of the outermost layer, called variously guanophores, leukophores, ochrophores, iridocytes and interference cells, are yellowish in colour; so far as is known, these cells do not alter either in shape or tint. Underneath these are the melanophores, also a similar but reddish type of cell called erythrophores. To take the melanophores, these send processes towards the surface more or less encircling the guanophores. Darkening in the colour of the chameleon is due to the migration of granules of melanin from the deeper portion of the melanophores into the more superficial tentacles which surround the guanophores. The actual colour which the animal presents is partly due to the mixture of colours which the various pigment cells present, and partly due to the scattering of light between these. The migration of the melanophore granules in the chameleon is due largely to the hormone adrenalin. The current belief that the chameleon takes on the colour of its surroundings is much exaggerated; the colour is influenced largely by light and temperature, and, so far as the author has been able to judge, in a very limited way by temper also; if the chameleon were annoyed it took on a darker colour.

Fish, too, have great powers of colour change within a certain scale of colours, which scale does simulate very closely the colour of the bottom on which they lie. Their colour change is also wrought by melanophores, but these seem more directly to be controlled by the nervous system and less by hormones than those of the frog. Thus, if a nerve going to a particular segment of the skin be severed the possibility of colour change appears to vanish.

The Chemical Nature of Melanin.—Melanin is closely related to two remarkable chemical substances found in the body. The one is the hormone adrenalin (which turns a blackish colour on exposure); the other is a substance, tyrosine, which is one of the breakdown products of protein.

The chemistry of melanin formation has been studied chiefly in the vegetable kingdom. A familiar example is seen when an apple is cut and the cut surface is exposed to air. The melanin is formed from tyrosine in the apple by oxidation; but the mere exposure of tyrosine to air will not produce melanin. There must also be a ferment present which effects the oxidation. This ferment is called tyrosinase. If two solutions—(1) tyrosine and (2) tyrosinase—both of which are colourless—be mixed and shaken with air the mixture first becomes a reddish colour and gradually turns to a dark brown. The reddish pigment appears to be an intermediate body between tyrosine and melanin. Recently, Raper and his colleagues have shown that the rôle of the tyrosinase lies in the formation of this reddish substance, the melanin being a more complicated body derived from the union of two molecules of this red substance.

The pigments in hair are formed on similar lines to those of skin. H. Onslow, the leading authority at the time of his death, wrote: "The colour of human hair depends upon the colour and form of the pigment (*i.e.*, whether it is diffused or deposited in granules) and upon the (air) vacuoles. . . . In light and sandy hair the pigment is chiefly diffused and of a yellowish red colour, but in darker hair the pigment is present as dark brown or black granules." Onslow recognizes three pigments in rabbits giving rise to six colours, the pigments being black, chocolate and yellow, which give rise to rabbits of those colours, and, when the pigments are diluted, to blue, fawn and cream respectively. The pigments may, however, be mixed, or in bands, giving rise to the agouti. With regard to whiteness, Onslow writes: "The hair of an animal may be white for one of three reasons—(1) the absence of either chromogen or enzyme; (2) the absence of both chromogen and enzyme; (3) the presence of an inhibitor of the enzyme."

Whilst most of the pigments in the integument consist either of melanin or some substance closely allied to it, a few are of quite a different origin.

The beak and the legs of fowl, for instance, are often yellow, the pigment being one known as carrotin—the same that colours the carrot. Its presence is, in a sense, accidental. It is not manufactured in the animal body, but exists in the vegetables eaten. It is absorbed into the blood during digestion and, being soluble in fat, it accumulates in places where fat exists. More especially is this the case in the yolk of the egg. Hens fed on foods com-

pletely free of pigment after a time lay eggs with colourless yolks; moreover, if fed on food containing other fat soluble pigments, the yolk becomes correspondingly coloured; eggs with bright red yolks are obtained if the dye "Soudan III." be mixed into the food.

It is remarkable that haemoglobin contributes little to the pigmentation of the skin—in man only in pathological conditions. In jaundice the yellow pigment is the same as ordinarily appears in the bile, and is practically haemoglobin stripped of its iron and of its protein. Closely related to bile pigment is uro-porphyrin, which occasionally appears in the skin, and then with very distressing results. The skin becomes exceedingly sensitive to light so that the individual requires veiling in the open air; otherwise he would suffer from sunburn amounting to inflammation.

Another sort of porphyrin is, however, found in the integument of some of the lower animals, as for instance, the brown line on the back of the earth-worm This is protoporphyrin; it is the pigment which forms the basis of haemoglobin and is most familiar as being that which colours brown eggs.

Finally, the distinction between *pigment* and *colour* must not be forgotten. Black eyes and blue contain the same pigment—melanin—black more than blue, but the blue hue is obtained from the way in which the light is reflected from the surfaces of the fibres of which the iris is made, and among which a number of pigment cells are disposed. (J BAR)

PIGOT, GEORGE, BARON (1719–1777), English governor of Madras, was born on March 4, 1719 and entered the service of the East India Company in 1736. He became governor and commander-in-chief of Madras in 1755 Having defended this place against the French in 1758–59 and occupied Pondicherry on behalf of the company, he resigned office in November 1763 and returned to England, being made a baronet in 1764 In the following year he obtained a seat in parliament, which he retained until his death, in 1766 he was created an Irish peer as Baron Pigot. Returning to India in 1775 to occupy his former position at Madras, Pigot was at once involved in a quarrel with the majority of his council, which arose out of the proposed restoration of the rajah of Tanjore. The governor was arrested by order of his opponents, and was still a prisoner when he died on May 11, 1777. In 1779 the matter was discussed in parliament, and four of those who were responsible for his arrest were tried and fined £1,000 each. Pigot, who left several illegitimate children, was never married, and his barony became extinct

PIG-STICKING or **HOG-HUNTING** is the sport of chasing the wild boar on horseback with a spear From the earliest times the pursuit of the wild boar has been a favourite pastime in Europe but the modern sport of pig-sticking is of Indian origin. It is now generally accepted as a fact that pig-sticking was the outcome of bear-spearing, which was popular amongst British sportsmen in Bengal until the beginning of the 19th century when bears had become so scarce that wild boars were substituted as the quarry Early in the 19th century it seems that the spear was generally thrown and Captain Johnson, writing in 1827, gives directions for throwing the spear, which was a weapon more in the nature of a javelin with different coloured ribbons attached to the butt so as to enable the owner to reclaim his spear. In 1830 Mr Mills, of the I C S , seems to have introduced the "jobbing" spear in his district and this weapon was universally used in Bengal. But the jobbing, or thrusting, spear was known before 1830 and was used regularly by officers of Lord Lake's Army as early as 1803 (*vide War and Sport in India: an Officer's Diary, 1802–1806*). At the present time there are really three types of spear in general use: the short Bengal spear which is about 5 feet long and is always used over-hand; the long Bombay spear, which may be as long as 10 to 12 feet and is always used under-hand like a lance; and a spear about 6 to 7 feet long, well leaded at the butt so as to balance about a foot from that end, which is generally used under-hand but which can, should circumstances so demand, be used over-hand. This last is the type of weapon common in the United Provinces and Delhi districts. The best type of horse is one that is fast and quick, yet not too big, as very rapid twists and turns must be made when following a pig which "jinks," or turns sharp in its tracks. For this same reason the horse must be perfectly balanced and well back on its hocks, while a good shoulder and long rein help it to stand up over bad ground.

A large area of land is controlled and hunted by a "Tent Club" which corresponds to a Hunt in England, and private expeditions after pig in any such area are forbidden by etiquette. A Tent Club is managed by an honorary secretary, which is an unfortunate title as this individual has powers and prestige similar to those of a M F H. in England The season varies in different districts but begins as soon as the heavy undergrowth, which springs up during the monsoon, has died sufficiently to enable riding across country, usually in January, and continues throughout the hot weather until the rains break towards the end of June. April, May and early June are the best months. Meets of a Tent Club take place, as a rule, once a fortnight and last for two to four days There are two methods of hunting Where the whole country is covered with girth-high grass and jhow (tamarisk) a long line of beaters advances while the "spears" ride with the line. These are divided into "heats" of three or four and only one heat may ride a boar that is put up, or "reared," by the beaters, the heat nearest the boar taking the hunt The rider who gains "first spear," that is who spears the boar first, claims the head and tusks as his trophy But where the boar inhabits thick patches of unridable jungle, as is the case in Central India and Guzerat, as well as in isolated cases in other parts, the heats wait in hiding outside while beaters drive out the boar. The rules for riding are the same in both cases.

There are various pig-sticking competitions the best known of which is the Kadir Cup. The word "Kadir" (pronounced "Karder") merely means the old bed of a large river. All the big Indian rivers are constantly changing their courses and the land which has at one time been under water may be anything from five to thirty miles in width Such land is a river Kadir and is overgrown with tamarisk and grass, intersected with nullahs (*i e.,* water courses, dry or full of water), and dotted with *jhils* (swamps). Villages are few and far between, while the ground is the haunt of wild boar and many other species of game, both big and small A large part of the Ganges Kadir has been controlled by the Meerut Tent Club since before the Mutiny, and the Kadir Cup is run annually in March in this country Competitors may enter two horses, but not more. Heats of three are determined by lots, and the gainer of the first spear in each heat qualifies for the second round, and so on to the semi-final and final heats The winning of the Kadir Cup, which was instituted in 1869, constitutes the blue ribbon of pig-sticking

Other pig-sticking competitions are the Guzerat Cup, which is run in Guzerat on similar lines to the Kadir Cup; the Nagpur Hunt Cup, which goes to the member of the Tent Club who gains the greatest number of first spears in the season, and the Muttra Cup, which was instituted in 1913 and is awarded to a team of three who actually kill the greatest proportion of boars to those hunted This event is run in the Jumna Kadir near Muttra.

Pig-sticking in India suffered severely during the War owing to the shortage of spears and many old Tent Clubs were automatically disbanded through lack of members and funds But there has been a great revival since 1919 and almost all the old Clubs have been resuscitated; the sport is as popular now as it has ever been in the past, and in 1927 one of the largest boars ever recorded as being speared was killed in the Gogra Kadir by the Fyzabad Tent Club This boar measured 37¾ inches at the withers and weighed 325 pounds.

The only other country where pig-sticking is practised is in Tangier, where there is a flourishing Tent Club.

Useful books on the subject are F B Simpson, *Letters on Sport in Eastern Bengal*, A E Wardrop, *Modern Pig-Sticking;* Sir R S S. Baden-Powell, *Pig-Sticking or Hog-Hunting* (G. BU.)

PIGWEED, a name applied to various plants, especially lamb's-quarters (*q v.*) and various species of amaranth (*q.v.*). The winged pigweed (*Cycloloma atriplicifolium*), of the Great Plains region of North America, is closely allied to lamb's-quarters. *See* illustration on page 924.

PIKE, ZEBULON MONTGOMERY (1779–1813), American explorer and soldier, was born at Lamington, Somerset county, N.J., the son of Zebulon Pike (1751–1834) a captain in the Revolutionary War, who remained in Federal service until 1812. The son entered his father's company as a cadet about 1794, and in 1799 or 1800 was commissioned first lieutenant. When in 1805 President Jefferson wished the upper Mississippi region of the Louisiana Purchase explored, Lieut. Pike, then 26 years of age, was selected to lead the expedition. With 20 soldiers he ascended the Mississippi from St. Louis past the Falls of St. Anthony to a place in Morrison county, Minn. Hence he made an expedition on foot to the fur-trading posts of the Northwest Company, a British concern, at Sandy, Leech and Cass Lakes, and took formal possession for the United States. He returned to St. Louis in April, 1806, and almost immediately was despatched at the head of an expedition to treat with Indian tribes and explore the country west and south-west of St. Louis to the headwaters of the Arkansas and Red rivers. After holding a grand council of the Pawnees, he ascended the Arkansas river through the Royal Gorge, and came in sight of the mountain which was named Pike's Peak in his honour. While searching for the Red river he came to the South Platte, marched through South Park, left it by Trout Creek pass, struck over to the Arkansas, which he thought was the Red river for which he was searching, and, going south and south-west, came to the Rio Grande del Norte (about where Alamosa, Conejos county, Colorado, is now) on the 30th of January 1807. There on the 26th of February he and a small number of his men were taken prisoners by Spanish authorities, who sent him first to Santa Fe, then to Chihuahua to General Salcedo, and by a roundabout way to the American frontier, where he was released on the 1st of July 1807. He was promoted captain (August 1806), major (May 1808), lieutenant-colonel (Dec. 1809) and colonel (July 1812). In 1808 he tried in vain to get an appropriation from Congress for himself and his men. He was military agent in New Orleans in 1809–1810, was deputy quartermaster-general in April–July 1812, and was in active service in the War of 1812 as adjutant and inspector-general in the campaign against York (now Toronto), Canada, and in the attack on York on the 27th of April 1813 was in immediate command of the troops in action and was killed by a piece of rock which fell on him when the British garrison in its retreat set fire to the magazine, just as his victorious soldiers were breaking in.

ROUGH PIGWEED (ROOT ON RIGHT)

His *Account of an Expedition to the Sources of the Mississippi and through the Western Parts of Louisiana . . . and a Tour through the Interior Parts of New Spain* was published at Philadelphia, 1810; rearranged and reprinted in London, 1811, and has been published in many editions since, including translations into the French and Dutch. The standard edition with memoir and notes by Elliott Coues was published in 1895. In 1908 H. E. Bolton published some of the papers taken from Pike in Mexico (originals then in Mexican archives but forwarded to Washington in 1910) in the *American Historical Review* (vol. xiii., 798–827).

See the sketch by H. Whiting in vol. V., Ser. 2, of Jared Spark's *Library of American Biography.*

PIKE, fresh-water fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (*Esocidae*) of soft-rayed fishes. They are recognized by their elongate compressed body covered with small scales, a long head, long spatulate snout, and large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point backwards or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the tail, thus greatly increasing the propelling power of the fish. Although pike lead rather a sedentary life, they are excelled by no other fresh-water fish in rapidity of motion when they dash upon their prey or dart out of reach of danger. In the Old World one species only is known (*Esox lucius*), which prefers lakes and sluggish reaches of rivers. It extends into Lapland in the north and as far south as central Italy and Constantinople, but is absent in Spain and Portugal The European species occurs also in eastern North America, and is common southwards to northern Ohio. But North American waters are tenanted by other species of pike of which the largest is the muskelunge or maskinonge of the Great Lakes (*E. nobilior*). The other American pike are smaller and generally named "pickerel." Pike are the most voracious of fresh-water fish. Large specimens will seize rats or water-voles, and are said to attack even foxes and small dogs. Individuals of *E. lucius* of 50 lbs. are not scarce, but much larger ones are on record. Pike are wholesome food, and are much esteemed in inland countries. According to the season and the climate they spawn in April or in May and sometimes as early as February.

PIKE (ESOX LUCIUS)

PIKE, a word which, with its collateral forms "pick" and "peak," has as its basic meaning "anything pointed or tapering to a point." The ultimate etymology is much disputed, and the interrelation of the collaterals is very confused. In Old English there are two forms (*pic*), one with a long and the other with a short vowel, which give "pike" and "pick" respectively. The first form gave in the 15th century the variant "peak," first with reference to the peaked shoes then fashionable, *pekyd schone*. In Romanic languages are found Fr. *pic*, Span. *pico*, Ital. *piccare*, to pierce, etc. There are also similar words in Welsh, Cornish and Breton. The Scandinavian forms, *e.g.*, Swed. and Nor. *pik*, are probably taken from English. While some authorities take the Celtic as the original, others look to Latin for the source. Here the woodpecker, *picus*, is referred to, or more probably the root seen in *spica*, ear of corn, and *spina*, prickle (English spike, spine). The current differentiation in meanings attached to pike, pick and peak are more or less clearly marked, though in dialects they may vary. Apart from the use as the name of the fish (*see* above), probably a shortened form of pike-fish, from its sharp, pointed beak, the common uses of the word are for a long hafted weapon with sharply pointed head of iron or steel, the common weapon of the foot-soldier till the introduction of the bayonet (*see* SPEAR, HALBERT, and BAYONET), and for a hill with a pointed summit, appearing chiefly in the names of such hills in Cumberland, Westmorland and North West Lancashire.

PIKE-PERCH, fresh-water fishes allied to the perch, but with strong teeth standing between smaller ones. They resemble the pike in their elongate body and head, and are dangerous enemies to other fresh-water fishes. They are excellent eating. In Europe two species occur, the more celebrated being *Lucioperca sandra*. It prefers the quiet waters of large rivers and clear, deep lakes, in which it reaches a weight of 25 to 30 pounds The second (*L. wolgensis*) is limited to rivers in southern Russia and Hungary. In North America two are distinguished; viz., *L. americana,* which grows to a weight of 20lb., and the smaller *L. canadensis;* both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PIKE'S PEAK, a famous mountain of the Rampart range of the Rocky Mountains in El Paso county, Colorado, U.S.A. Though surpassed in altitude (14,108 ft.) by many summits in the State, few have so commanding a location and none is so well known. From the summit the magnificent Sangre de Cristo range is in the foreground, while on a clear day not only its southernmost summit, Blanca Peak (14,390 ft.) is visible, but also the Spanish

Peaks (12,708 and 13,623 ft.) 100 m to the south, and Long's Peak 100 m to the north, and between them Mt. Lincoln, Gray's Peak and other giants, while the view extends eastward over a vast sweep of plains. At the base of the mountain are Manitou and Colorado Springs, whence tourists can make the ascent of the peak on horseback, by a cog-railway, 8·75 m long (opened in 1891), or by a well constructed automobile road

The lower slopes are covered with evergreen forests but the upper 2,500 ft. of the peak is bare granite. The summit is a comparatively level spot of nearly 60 ac extent. Pike's Peak was discovered in Nov. 1806 by Lieut Zebulon M Pike In 1819 it was first climbed by the exploring party of Major S H Long.

PIKES PEAK OCEAN TO OCEAN HIGHWAY, an American highway extending from New York city to San Francisco, Calif , a distance of 3,564 miles. Its central location makes it one of the most direct routes from ocean to ocean It runs directly past the base of Pikes Peak, up which is the Pikes Peak motor road, the highest in the world The roadway is paved hard and improved from the Atlantic to the Rockies and partly paved, hard, improved and graded the remainder of its length From New York city to Pittsburgh, Pa., this highway is also known as the William Penn highway. Columbus. O , Indianapolis, Ind , Springfield, Ill , St Joseph, Mo , Colorado Springs, Colo , Salt Lake City, Utah, Reno, Nev , and Sacramento, Cal., mark the general course of the highway.

PILATE, PONTIUS, of equestrian rank, was Roman governor of Judaea from A.D. 26 to A D 36, when he was recalled He kept the Roman peace in Palestine, but with little understanding of the people (Josephus, *Ant.* XVIII., iii., 1, 2; iv. 1, 2; *Jewish War*, II., ix., 2–4, Philo *ad Caium*, 38). One disturbance arose when Pilate used Temple funds for an aqueduct The reference in Luke xiii., 1, to the massacre of Galilean pilgrims in the act of sacrificing suggests the governor's ruthlessness in putting down riot It must be said, however, that the post of Roman Governor in Judaea was peculiarly difficult and it was to Pilate's credit that his rule lasted as long as ten years Both Pilate's part in responsibility for the crucifixion of Jesus Christ and the legal aspects of the trial have been much debated The Early Church blamed the Jews, and correspondingly tended to exonerate Pilate. The Third and Fourth Gospels, especially, suggest that extraordinary pressure was brought to bear upon the governor by the Jewish priests. Pilate may well have been impressed by the dignity and gentleness of the great Preacher of the Kingdom of God, and may also have given Him opportunity to save Himself (John xviii , 33–38; XIX , 9–11) There are many stories, all of uncertain value and in many cases legendary, telling of Pilate's later life and of his suicide. Pilate has been canonized in the Abyssinian church (June 25) and his wife Procla, or Procula, in the Greek (Oct 27)

PILCHARD or **SARDINE** (*Sardina pilchardus*), a fish of the herring family, found on the Atlantic coasts of Europe north to the English channel, and represented in the Mediterranean by a smaller race (*S pilchardus sardina)* The genus *Sardina* includes also *S sagax* of Japan, California, Chile and South Africa, and *S neopilchardus* of southern Australia and New Zealand These resemble the European pilchard in being slender rounded fishes, with feeble teeth, with radiating ridges on the operculum, and with rich oily flesh The European fish is distinguished by a remarkable peculiarity, every alternate oblique row of scales being enlarged and covering the row behind it, so that the scales appear to number about 27 instead of 54 in a longitudinal series; exceptional specimens, with the scales on one side equal and apparently more numerous, have been described as hybrids between pilchard and herring! Pilchards swim in large shoals and feed on minute pelagic animals; they spawn in summer and their eggs float in the water; in the larva the dorsal fin is placed far back, and as the fish grows it migrates forwards to its position in the middle of the length of the fish. In Cornwall adult fish, about 10 in. long, are caught and are salted in barrels. The sardine industries of France and Portugal depend on smaller fish, which are tinned in oil Tinned Californian pilchards and Japanese sardines are also important products

PILE. As a textile term, this word indicates the surface of a cloth composed of an infinite number of loops of warp threads, or else of an infinite number of free ends of either warp or weft (filling) threads that stand erect from the foundation or ground structure of the cloth There are two general methods of distinguishing between such cloths; thus.—

1 When the loops are uncut, the pile is usually termed "looped pile."

2 When the same or similar loops are cut, either in the loom during weaving or by a special machine after the cloth leaves the loom, the pile is termed "cut pile "

Other names applied to such cut-pile fabrics in which the effect is formed by the *warp* threads are "velvet" and "plush," the former being used to define short-pile fabrics and the latter to define long-pile fabrics The word "velveteen" is used to distinguish the fabric when the pile is formed of *weft* or filling threads that have been cut.

Amongst the loop-pile fabrics may be mentioned Brussels tapestry and imitation Brussels carpeting, as well as Moquettes and the like. In some cases the surfaces of carpets, such as Wilton and Axminster, are formed of cut pile; and again, in other instances, both looped (uncut pile) and cut pile appear on the surface of the same fabric Imitation sealskins and several other kinds consist of mono-coloured pile, whereas all the above-mentioned carpets have surfaces upon which decorative designs appear in both kinds of pile and in several colours. (*See* CARPET; CARPET MANUFACTURE. For pile in building *see* FOUNDATIONS) (T. W)

PILGRIMAGE, a journey undertaken, from religious motives, to some place reputed as sacred These journeys play an important rôle in most pre-Christian and extra-Christian religions in the Catholic Church their acceptance dates from the 3rd and 4th centuries

The Pilgrimage in Pre- and Non-Christian Religions.—To the Germanic religions the pilgrimage is unknown. On the other hand, it is an indigenous element, not only in the creeds of Asia, but in those of the ancient seats of civilization on the Mediterranean The fundamental conception is always that the Deity resides—or exercises a peculiarly powerful influence—in some definite locality, and to this locality the devout repair, either in reverence of their god, or in quest of his assistance and bounty

One of the oldest homes of the pilgrimage is India There the army of devotees tends more especially to the Ganges—the hallowed river of Hindu belief. On the Ganges lies Benares, the holy city of Brahmanism and to look on Benares, to visit its temples and to be washed clean in the purifying river, is the yearning of every pious Indian Even Buddhism—originally destitute of ceremonial—has adopted the pilgrimage; and the secondary tradition makes Buddha himself determine its goals the place where he was born, where he first preached, where the highest insight dawned on him, and where he sank into Nirvana

The habit of religious expeditions to sacred places took deep root among the Egyptians, the Jews, and the Greeks, but the pilgrimage attained its zenith under Islam. For Mohammed proclaimed it the duty of every Mussulman, once at least in his life to visit Mecca; the result being that the birth-place of the Prophet is now the religious centre of the whole Mohammedan world. (*See* ISLAM; CARAVAN; MECCA.)

THE PILGRIMAGE UNDER CHRISTIANITY

The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested It was a religion without temples, without sanctuaries, and without ceremonial The

saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. The Christian pilgrimage arose from devotion to the memory of Jesus; the faithful repaired to those places which were invested with memories of their Lord's earthly life. Bethlehem and Jerusalem became objects of such visits from the 2nd century; and from references in Eusebius and others, it is evident that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer; and that men travelled for purposes of prayer implies acceptance of the theory of sanctuaries which it is an act of piety to visit.

THE PILGRIMAGE IN THE ANCIENT CHURCH

The East.—In the passages cited above, Bethlehem and the Mount of Olives figure as the main goal of the pilgrim: and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. The one holy site in the town of Jerusalem, before the time of Constantine, was the so-called *Coenaculum,* which received its name in later years. It was regarded as the house in which—according to the Acts of the Apostles (xii. 12 *sqq.*)—Mary, the mother of John Mark, lived; and the belief was that there the Lord held the Last Supper, and that there the eleven assembled after the Ascension

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites, under Constantine the Great, as described by Eusebius in his biography of the emperor (iii. 25 *sqq.*). At the order of Constantine, the accumulation of rubbish covering the supposed site of the burial-place of Jesus was removed, and the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326–336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. The result was an exaggerated importance attached to these pilgrimages, a view which led to energetic protests, especially from Gregory of Nyssa, who composed a monograph on the pilgrimages (*De iis qui adeunt Hierosol.*). Jerome, like Gregory, insists on the point that residence in Jerusalem has in itself no religious value: it is not locality, but character, that avails, and the gates of Heaven are as open in Britain as in Jerusalem (*Ep.* 58, 3).

But Jerome never denied the religious uses of the pilgrimage; he considered it an act of faith for a man to offer his prayers where the feet of the Lord had stood, and the traces of the Birth, of the Cross, and of the Passion were still to be seen (*Ep.* 47, 2). With the number of the pilgrims the number of pilgrim-resorts also increased. Of Jerusalem alone Jerome relates that the places of prayer were so numerous that it was impossible to visit them all in one day (*Ep.* 46, 9). In the Holy Land the list was still longer: the natives were ready to show everything for which the foreigners inquired, and the pilgrim was eager to credit everything. In her expedition to the East, Paula, the friend of Jerome, visited, among other places, Sarepta and Caesarea. In the first-named place she was shown the tower of Elijah; in the second, the house of Cornelius, that of Philip, and finally the grave of the four virgins. At Bethlehem she saw, in addition to the church of the Nativity, the grave of Rachel; at Hebron the hut of Sarah, in which the swaddling clothes of Isaac and the remains of Abraham's oak were on view (Hieron. *Ep.* 108).

In the West.—While pilgrim-resorts were thus filling the East, their counterparts began to emerge in the West. And here the starting-point is to be found in the veneration of martyrs. Care for the tombs of martyrs was sanctioned by immemorial custom of the Church; but, in this case also, a later age failed to preserve the primitive conception in its purity; and Augustine himself was obliged to defend the usage of the Church from the imputation that it implied a transference of heathen ceremonial to the sphere of Christianity (*Contr. Faust.* xx. 21). The martyrs were the local heroes of particular communities; but there were men whose life and death were of significance for the whole of Christendom—the apostles. Of these Peter and Paul had suffered martyrdom in Rome, and it was inevitable, from the nature of the case, that their graves should soon become a resort, not only of Romans born, but of strangers also. The Roman cemeteries were visited by numerous pilgrims even in the 3rd century: for the earliest *graffiti* in the papal crypt of the Coemeterium Callisti must date from this period (De Rossi, *Roma sotter.* i. 253 *sqq.;* Kraus, *Rom. Sott.* 148 *sqq.*).

Pilgrims were drawn to the graves of the saints convinced that there divine succour was certain; hence came the belief in a never-ending series of miracles there performed. Doubt was unknown. St. Augustine observes that, though Africa was full of martyrs' tombs, no miracle had been wrought at them so far as his knowledge extended. This, however, did not lead him to doubt the truth of those reported by others—a fact that is somewhat surprising when we reflect that the phenomenon caused him much disquiet and perplexity. Who, he asks, can fathom the design of God in ordaining that this should happen at one place and not at another? And eventually he acquiesces in the conclusion that God, who gives every man his individual gift at pleasure, has not willed that the same powers should have efficacy at every sepulchre of the saints (*Ep.* 78, 3).

THE PILGRIMAGE IN THE MIDDLE AGES

The mediaeval Church adopted the custom of the pilgrimage from the ancient Church. The young Germanic and Romance nations did precisely as the Greek and Romans had done before them, and the motives of these devotional journeys—now much more difficult of execution in the general decay of the great world-system of commerce—remained much the same. They were undertaken to the honour of God, for purposes of prayer, or in quest of assistance, especially health. But the old causes were reinforced by others of at least equal potency. The mediaeval Church was even more profoundly convinced than its predecessor that the miraculous power of Deity attached to the bodies of saints and their relics. But the younger nations—French, English and German—were scantily endowed with saints; while, on the other hand, the belief obtained that the home-countries of Christianity, especially Rome and Jerusalem, possessed an inexhaustible supply of these sanctified bodies.

Pilgrimages were consequently undertaken with the intention of securing relics. At first it was enough to acquire some object which had enjoyed at least a mere connection with the hallowed corpse. One enthusiast took a little wax dropped from the taper; another, a portion of the dust which lay on the grave; a third, a thread from the cloth covering the sarcophagus; still another plucked the flowers which visitors had planted above the tomb Before long, however, these humble trophies failed to content the pilgrims, and they began to devote their efforts to acquiring the actual bodies, or portions of them—frequently by honest means, still oftener by trickery. One of the most attractive works of early mediaevalism—Einhard's little book, *Translatio Marcellini et Petri*—gives a vivid description of the methods by which the bodies of the two saints were acquired and transported from Rome to Seligenstadt on the Main.

Far more important consequences, however, resulted from the fact that the mediaeval mind associated the pilgrimage with the forgiveness of sins. This conception of the pilgrimage, as a means of expiation or a source of pardon for wrong, was foreign to the ancient Church. It is quite in accordance with the keener consciousness of sin, which prevailed in the middle ages, that the expiatory pilgrimage took its place side by side with the pilgrimage to the glory of God. The pilgrimage became an act of obedience; and, in the books of penance (*Poenitentialia*) which date from the early middle ages, it is enjoined as an expiation for many of the more serious sins, especially murder or the less venial forms of

unchastity. The place to be visited was not specified; but the pilgrim, who was bound by an open letter of his bishop to disclose himself as a penitent, lay under the obligation, wherever he went, to repair to the churches and—more especially—the tombs of the saints, and there offer his prayers. On occasion, a chain or ring was fastened about his body, that his condition might be obvious to all; and soon all manner of fables gained currency. how, here or there, the iron had sprung apart by a miracle, in token that the sinner was thereby absolved by God.

As the system of indulgences (*q v*) developed, a new motive came to the fore which rapidly overshadowed all others: pilgrimages were now undertaken to some sacred spot, simply in order to obtain the indulgence which was vested in the respective church or chapel. In the 11th century the indulgence consisted in a remission of part of the penance imposed in the confessional, in return for the discharge of some obligation voluntarily assumed by the penitent Among these obligations, a visit to a particular church, and the bestowal of pious gifts upon it, held a prominent place; and during the whole period of mediaevalism, the number of pilgrims was perpetually on the increase

The Pilgrim Resorts.—The most important places of resort both for voluntary and involuntary pilgrimages, were still Palestine and Rome. On the analogy of the old *Itineraria*, the abbot Adamnan of Iona (d. 704) now composed his monograph *De locis sanctis*, which served as the basis of a similar book by the Venerable Bede (d. 735) His authority was a Frankish bishop named Arculf, who resided for nine months as a pilgrim in Jerusalem, and visited the remaining holy sites of Palestine in addition to Alexandria and Constantinople. Of the later itineraries the *Descriptio terrae sanctae*, by the Dominican Burchardus de Monte Sion, enjoyed the widest vogue. This was written between the years 1285 and 1295, but books of travel in the modern tongues had already begun to make their appearance The initiative was taken by the French in the 12th and 13th centuries, and the Germans followed in the 14th and 15th, while the *Book of Wayes to Jerusalem* of John de Maundeville (*c* 1336) attained extreme popularity, and was translated into almost all the vernacular languages

As a result of this steady increase in the number of pilgrims, the old arrangements for their accommodation were found deficient Consequently hospices arose which were designed exclusively for the pilgrim Those on the Alpine passes are common knowledge The oldest, that on the Septimer pass, dates from the Carolingian period, though it was restored in 1120 by the bishop Wido of Chur that on the Great St Bernard was founded in the 10th century, and reorganized in the 13th To this century may also be assigned the hospice on the Simplon, to the 14th those on the St Gothard and the Lukmanier Similarly, the Mediterranean towns, and Jerusalem in particular, had their pilgrim-refuges Service in the hospices was regularly performed by the hospital-fraternities—that is to say, by lay associations working under the authorization of the Church The most important of these was the fraternity of the *Hospitale hierosolymitanum*, founded between 1065 and 1075; for hence arose the order of St. John, the earliest of the orders of knighthood. (*See* ST. JOHN OF JERUSALEM, KNIGHTS OF.) In addition to the hospital of Jerusalem, numerous others were under its charge in Acre, Cyprus, Rhodes, Malta, etc Associations were formed to assist pilgrims bound for the East; one being the *Confrérie des pèlerins de Terre-Sainte* in Paris, founded in 1325 by Louis de Bourbon, count of Clermont (afterwards first duke of Bourbon).

But since, in the middle ages, the Holy Land was no longer held by a Christian Power, the protection of the pilgrims was no less necessary than their sustenance. This fact, after the close of the 11th century, led to the Crusades (*q.v.*), which in many respects are to be regarded as armed pilgrimages. For the old dream of the pilgrim, to view the country where God had walked as man, lived on in the Crusades—a fact which is demonstrated by the letters of Bernard of Clairvaux, with the songs of Walther von der Vogelweide and other Crusaders. And, since the strongest motive in the pilgrimage was the acquisition of indulgences, unnumbered thousands were moved to assume the Cross, when, in 1095, Urban II promised them plenary indulgence. The conquest of Jerusalem, and the erection of a Christian empire in Palestine, naturally welled the influx of pilgrims. And though in 1187 the Holy City again fell into the hands of the infidel, while in 1291 the loss of Acre eliminated the last Christian possession in Palestine, the pilgrimages still proceeded. It was not till the Reformation, the wars of the 16th century, and the loss of Rhodes, Candia and Cyprus to the Turks, that any appreciable alteration was effected When Ignatius de Loyola (*q v*) set sail in 1523 from Venice to Palestine, only some thirteen souls could be mustered on the pilgrim-ship, while eight or nine others sailed with the Venetian state-vessel as far as Cyprus A considerable number had abandoned their pilgrimage and returned home on the news of the fall of Rhodes

For pilgrimage overseas, as it was styled, the permission of the Church was still requisite The pilgrims made their journey in grey cowls fastened by a broad belt On the cowl they wore a red cross, and a broad-brimmed hat, a staff, sack and gourd completed their equipment. During their travels the beard was allowed to grow, and they prepared for departure by confession and communion Of their hymns many are yet extant ("Jerusalem mirabilis," "In gottes namen faren wir," etc.) Ships belonging to the knights of St John and the Knights Templars conducted the commerce with Palestine, and the pilgrims formed themselves into unions, elected a "master" and concluded their agreements, as to the outward voyage and return, in common The expenses of the journey to Palestine were no light matter In the 12th century they may be estimated at 100 marks of silver (£200) for the ordinary pilgrim. The expenses of the princes and lords were, of course, much heavier Duke William of Saxony who was in Jerusalem in 1461, spent no less than £10,000 on his journey (*See* Prutz, *Kulturgeschichte der Kreuzzuge*, pp. 106 *sqq*; Rohricht, *Deutsche Pilgerreisen*, p 42)

Great as was the number of pilgrims oversea, it was yet far exceeded by that of the visitants to the "threshold of the apostles," *i e*, Rome, which received their greatest impetus through the inauguration of the so-called Year of Jubilee

Of the other pilgrim-resorts, we shall only emphasize the most important Priority of mention is due to St James of Compostella (Santiago, in the Spanish province of Galicia). Here the attraction for the pilgrim was the supposed possession of the body of James the son of Zebedee The first connection of the apostle with Spain is to be traced in the *Poema de aris b Mar et xii apost dedic*, which is ascribed to Aldhelm (d 709) and contains a story of his preaching in that country The earliest account of the transference of his relics to the Peninsula is found in Notker Balbulus (d 912, *Martyrol in Jul xxv*). But in Spain belief in this cherished possession was universal, and, step by step, the theory won credence throughout the West In England indeed, the shrine of St James of Compostella became practically the most favoured devotional resort, and in the 12th century its visitation had attained such popularity that a pilgrimage thither was ranked on a level with one to Rome or Jerusalem In France St Martin remained the chief goal of the pilgrim; while Notre Dame de Sous-Terre in Chartres (with a portrait of the "black Virgin"), Le Puy-en-Velay (dep. Haute Loire), and others, also enjoyed considerable celebrity In England pilgrimages were made to the tomb of the murdered archbishop, Thomas à Becket, in Canterbury Cathedral The setting of Chaucer's *Canterbury Tales* gives a vivid idea of the motley company of pilgrims; but it seems probable that Germany also sent a contingent In addition, Walsingham, Peterborough, St. Davids, Holywell, and St Andrews in Scotland were much frequented In lower Germany, Cologne and Aix-la-Chapelle, in Switzerland Einsiedeln, were the principal resorts

In Italy the church of the Archangel on Mt Gargano was one of the most ancient centres of the pilgrimage Later the Portiuncula church at Assisi displaced all other resorts, with the exception of Rome; but in the 15th century it was overshadowed in turn by the "Holy House" at Loretto on the Adriatic. According to an extravagant legend, the house of Joseph and Mary in Nazareth was transported by angels, on the night of the 9th–10th of May

1291 to Dalmatia, then brought to the Italian coast opposite (Dec. 10, 1294), till, on the 7th of September 1295 it found rest on its present site. The pilgrimage thither must have attained great importance as early as the 15th century; for the popes of the Renaissance found themselves constrained to erect an imposing pilgrim church above the "Holy House."

The significance of the pilgrimage for the religious life of later mediaevalism cannot be adequately estimated. The possession of any extraordinary relic was everywhere considered a sufficient claim for the privileges of indulgences; and wherever this privilege existed, there the pilgrims were gathered together. All these pilgrimages, great and small, were approved and encouraged by the Church. And yet, during the whole of the middle ages, the voice of suspicion in their regard was never entirely stilled. Earnest men could not disguise from themselves the moral dangers almost inevitably consequent upon them; they recognized, moreover, that many pilgrims were actuated by extremely dubious motives; and they distrusted the exaggerated values set on outward works. The Roman papacy had no more zealous adherent than Boniface; yet he absolutely rejected the idea that Englishwomen should make the journey to Rome, and would willingly have seen the princes and bishops veto these pilgrimages altogether (*Ep.* 78). The theologians who surrounded Charlemagne held similar views.

When the abbess Ethelburga of Fladbury (Worcestershire) found her projected pilgrimage impracticable, Alcuin wrote to her, saying that it was no great loss, and that God had better designs for her: "Expend the sum thou hast gathered for the journey on the support of the poor; and if thou givest as thou canst, thou shalt reap as thou wilt" (*Ep.* 300). Bishop Theodulf of Orleans (d. 821) made an energetic protest against the delusion that to go to Rome availed more than to live an upright life (*Carm.* 67). To the same effect, the synod of Chalon-sur-Saône (813) reprobated the superstition which was wedded to the pilgrimage (*c.* 13); and it would be easy to collect similar judgments, delivered in every centre of mediaevalism. But, fundamentally, pilgrimages in themselves were rejected by a mere handful: the protest was not against the thing, but against its excrescences.

The Modern Pilgrimage.—The Reformation eradicated the belief in the religious value of visits to a particular locality. It is only pious memory that draws the Protestant to the sites consecrated by ecclesiastical history. On the other hand, while in the Eastern Church things have undergone little change the developments in the Roman Church show important divergences. The Year of Jubilee, in 1525, was unprecedented in its scant attendance, but the jubilees of 1575 and 1600 again saw great armies of pilgrims marching to Rome (*see* JUBILEE, YEAR OF). Fresh pilgrim resorts sprang up; mediaeval shrines, which had fallen on evil days, emerged from obscurity. The 19th century led to an extraordinary revival of the pilgrimage. Not only did new resorts spring into existence—*e.g.*, La Salette in Dauphiné (1846), and more particularly Lourdes (1858) in the department of Hautes Pyrénées—but the numbers once more attained a height which enables them to compete with the mediaeval figures. The dedication of the church of Lourdes, in 1876, took place in the presence of 30 bishops, 3,000 priests and 100,000 pilgrims. No new motives for the pilgrimage emerged in the 19th century, unless the ever-increasing cultus of the Virgin Mary may be classed as such, all of the new devotional sites being dedicated to the Virgin. For the rest, the desire of acquiring indulgences maintains its influence: but doubting voices are no more heard within the pale of the Roman Catholic Church.

PILGRIM FATHERS. In American history "Pilgrims" is applied to the earliest settlers of the colony of Plymouth, Mass., and its more specific application is to the first emigrants, who sailed in the "Mayflower" in 1620. They were from the beginning Separatists from the Church of England; they had established Independent (Congregational) churches at Scrooby and Gainsborough early in the 17th century, and some of them had fled to Amsterdam in 1608 to avoid persecution, and had removed to Leyden in the following year. They sailed from Delftshaven late in July 1620, from Southampton on Aug. 5, from Plymouth on Sept. 6 and late in Dec. 1620 founded the colony of Plymouth, Massachusetts. (*See* MASSACHUSETTS; PLYMOUTH and MAYFLOWER.)

PILGRIMS' WAY, THE. From Winchester, in Hampshire, England, to Canterbury, in Kent, runs a road or way which can still be traced, now on the present made roads, now as a lane, bridle path, or cart track, now only by a line of ancient yews, hollies or oaks which once bordered it. To this old track the name of Pilgrims' Way has been given, for along it passed the stream of pilgrims coming through Winchester from the south and west of England and from the continent of Europe by way of Southampton to Canterbury Cathedral to view the place of the martyrdom of Thomas Becket, in the north transept, the relics in the crypt where he was first buried after his murder, in 1170, and the shrine in the Trinity Chapel which rose above his tomb after the translation of the body in 1220. There were two festivals for the pilgrimage, on the 29th of December, the day of the martyrdom, and on the 7th of July, the day of the translation. The summer pilgrimage naturally became the most popular. In 1538 the shrine was destroyed and the relics of the saint scattered, but the great days of the pilgrimage had then passed. Erasmus gives a vivid picture of the glories of the shrine and of all that the pilgrims saw on his visit with Colet to Canterbury in 1514.

This road, although its name of the Pilgrims' Way has for long confined it to the road by which the pilgrims came to Canterbury from Winchester, follows a far older track. Right back into British and even older times the main direction which commerce and travellers followed across southern and western England to the Straits of Dover and the Continent lay from Canterbury along the southern chalk slope of the North Downs to near Guildford, then by the Hog's Back to Farnham. At this point the oldest track went across Salisbury Plain towards Stonehenge and so on to Cornwall. From Farnham westward the only portion of this, the oldest track that can now be traced, is a small portion that still bears the name of the Harrow (*i.e.*, hoary, old) road. It was in early times abandoned for the road from Winchester to which the stream of travel and commerce from the Continent and the south and south-west of England was diverted.

The ancient road has been traced fully in Mrs. Ady's book *The Pilgrims' Way* (1893), and the older track in the fullest detail in Hilaire Belloc's *The Old Road* (1904).

PILKINGTON, FRANCIS (d. 1638), English madrigal composer, the details of whose early life are obscure, took his Mus.B. at Lincoln college, Oxford. He was attached to Chester cathedral about 1604, and a few years later was ordained. His chief works include a book containing 21 vocal pieces and a pavin for the lute and bass viol (1605), *The First Set of Madrigals and Pastorals* (1614), and *The Second Set of Madrigals and Pastorals* (1624).

PILLAU, a seaport and watering-place in the Prussian province of East Prussia, on the spit of sand (*Nehrung*) which separates the Frische Haff from the Baltic, on the north of the entrance channel, and 29 m. by rail from Königsberg. Pop. (1925) 7,036. Pillau is the place where Gustavus Adolphus of Sweden landed in 1626. It did not obtain civic privileges until 1725, but was fortified shortly after that date. It has a harbour, which serves as the outer port of Königsberg, and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900–1901 constructed across the Frische Haff from Pillau to Königsberg. Pillau has a school of navigation, and is a well-known pilot station. Ship-building and fishing are carried on.

PILLNITZ, a village in the republic of Saxony, situated on the right bank of the Elbe, 5 m. above Dresden. Pop. (1925)

1,107. The new palace was built in 1818 on the site of a building which was burnt. The place became a residence of the electors of Saxony about 1700. By the convention of Pillnitz in August 1791 the emperor Leopold II. and Frederick William II., king of Prussia, agreed to take common action against any attack on the part of France.

PILLORY, an instrument of punishment which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame (as are the feet in the stocks) so as to be held fast, exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle, which secured the heads and hands of several persons at the same time, but it was commonly capable of holding only one.

In the statutes of Edward I. it is enacted that every pillory or "stretch-neck" should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially, and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. By the "Statute of the Pillory" (1266) the pillory was made the penalty for many small offences. In 1637 an attack was made on the Press, and the pillory became the recognized punishment of those who published books without a licence or libelled the Government. In 1816 the pillory was abolished except for perjury and subornation, and the perjurer Peter James Bossy was the last to stand in the pillory, at the Old Bailey for one hour on June 22, 1830. It was finally abolished in 1837 at the end of William IV.'s reign. In France the pillory, called *carcan,* was employed till 1832. In Germany it was known as *pranger.* The pillory was used in the American colonies, and provisions as to its infliction existed in the United States statute books until 1839; it survived in the State of Delaware until 1905. (*See* STOCKS.)

PILNYAK (1894-), Russian novelist. Boris Andreevich Vogau, who later took the pen name of Pilnyak, was born on Sept. 29, 1894 in Mojaisk, Moscow province. His childhood and early youth were spent on the Volga and among the peasants and the land administration "intellectuals." He studied economics at the Moscow commercial institute and began publishing stories in 1915. During the Bolshevik revolution Pilnyak lived in Moscow and also travelled through Russia studying the new conditions. In 1923 he visited England and Germany. His works deal with the first chaotic stage of transition from the old Tsarist Russia to the "new world" of the Soviet Republic. He is the most prominent figure in post-revolutionary fiction. His sympathies are with the peasants as opposed to the town and his stories are deliberately fragmentary and read like diaries and chronicles. His *Tales of the Wilderness* was translated by F. O'Dempsey (1924).

PILOCARPINE. This alkaloid (*see* ALKALOIDS) is a colourless oil which occurs in jaborandi leaves along with isopilocarpine and the related alkaloid, pilosine, $C_{16}H_{18}O_3N_2$ (Pyman, 1912). Pilocarpine, $C_{11}H_{16}O_2N_2$, was isolated independently by Hardy and by Gerrard in 1875. It boils at 260° C under 5mm. pressure, is freely soluble in water, alcohol, or chloroform, but not in ether or petroleum, and is dextro-rotary in solution. The salts crystallize well; the nitrate, which melts at 178° C, and the hydrochloride, whose melting point is 204–205° C, being those used in medicine. On evidence provided mainly by Jowett in England and Pinner in Germany a generally accepted constitutional formula for pilocarpine and isopilocarpine, which are regarded as stereoisomerides, has been put forward.

PILOÑA, a town of northern Spain on the Infiesto-Oviedo railway in the province of Oviedo; between the right bank of the river Piloña, a left-hand tributary of the Sella, and the Sierra de Abes (3,268 ft.). Pop. (1920) 18,323. Piloña is a densely populated mining and agricultural district.

PILOTAGE, as it is now understood, may be described as the art of conducting a vessel in or out of harbour, or in the neighbourhood of navigational dangers. The word "pilot" was formerly used to designate the steersman and later the sailing master; in fact, the art of piloting was divided into two parts: proper piloting, identical with what we now term navigating (*see* NAVIGATION), and common piloting, identical with the meaning of the word as given above. *See* PILOTAGE LAWS.

PILOTAGE LAWS. The present general British pilotage laws are contained in the Pilotage Act, 1913, which Act consolidated and amended the laws of pilotage as they existed under the Merchant Shipping Act, 1894. On the passing of the former Act, the Board of Trade, as the central authority, held enquiries, with the result that pilotage orders were made by it in respect of each District. Each pilotage order defines the limits of the district, names the pilotage authority therefor, states whether pilotage is compulsory or not therein, and empowers the authority to delegate any of its powers or duties to a pilotage committee, on which may sit representatives of both pilots and shipowners. The pilotage authority makes the necessary by-laws for the regulation of pilotage and pilots in its district, but these do not take effect until they are confirmed by the Board of Trade.

The principal pilotage authority is the Corporation of Trinity House, London, exercising jurisdiction in the London district, which extends from Orfordness to Selsea Bill, and in 38 other districts round the coasts of England and Wales. There are, however, about 60 other districts within which other pilotage authorities have jurisdiction.

Compulsory Pilotage.—A ship, whilst navigating in a district in which pilotage is compulsory, for the purpose of entering, leaving or making use of any port in that district, is required to be either under the pilotage of a licensed pilot of the district, or under the pilotage of a master or mate possessing a pilotage certificate for the district, who is bona fide acting as master or mate of the ship. A ship carrying passengers (other than an excepted ship) is, however, compelled to be under pilotage irrespective of whether the district in which she is navigating is a compulsory one or not. Under the Aliens Restriction (Amendment) Act, 1919, pilotage certificates cannot be granted to aliens, except to masters or mates of French nationality trading to the ports of Newhaven or Grimsby.

The following ships are excepted from compulsory pilotage: (1) Ships belonging to His Majesty. (2) Pleasure yachts. (3) Fishing vessels. (4) Ferry boats. (5) Ships of less than 50 tons' gross tonnage. (6) Ships exempted by by-law. (7) Tugs, dredgers, sludge vessels, barges and other similar craft belonging to or hired by a dock, harbour or river authority. (8) Ships calling at a port in a pilotage district for the sole purpose of taking on board or landing a pilot belonging to some other pilotage district.

The Board of Trade has the power, on the representation of parties interested, to revoke or vary any by-laws in a pilotage district, or require the pilotage authority to make by-laws. The licensing of a pilot by a pilotage authority does not involve any liability on the part of the authority for any loss occasioned by any act or default of the pilot.

Pilot Boats.—All pilot boats regularly employed in any district must be approved and licensed by the pilotage authority for that district, who may appoint or remove the masters thereof. Every pilot boat must be distinguished by the name of her owner and port on her stern, and her number on each bow, and the hull of the boat is usually painted black. When afloat the pilot boat must fly a red and white horizontal flag, known as a pilot flag, in a conspicuous position. A pilot flag must also be displayed by a vessel having on board a licensed pilot for the district, or a master or mate holding a pilotage certificate. The master of a ship subject to pilotage in a district must, under a penalty, display a pilot signal and keep it displayed until a licensed pilot comes on board, and if the master accepts the services of a pilot he must give him facilities for getting on board.

The following persons are liable to pay pilotage dues for any ship for which the services of a licensed pilot have been obtained, *viz.:* (a) the owner or master, or (b) the consignees or agents who have paid or are liable to pay any other charges on account of the ship, and these dues may be recovered in the same manner as fines under the Merchant Shipping Act, 1894. The pilotage dues on foreign ships, subject to compulsory pilotage, trading to and from

the port of London, have to be paid to the chief officer of customs and excise in that port, and such a ship may be detained until such dues are paid. It is an offence, punishable by a fine, if a licensed pilot demands or receives, and a master offers or pays, dues in respect of pilotage services at any other rates, whether greater or less, than those which are fixed by by-law.

Under section 633 of the Merchant Shipping Act, 1894, the owner or master of a ship was not answerable to any person for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of that ship within any district where the employment of a qualified pilot was compulsory by law. Section 15 of the Pilotage Act, 1913, however, reversed this defence of compulsory pilotage, and enacted that the owner or master of a vessel navigating under circumstances in which pilotage is compulsory is answerable for any loss or damage caused by that vessel, or by any fault of her navigation, in the same manner as he would if pilotage were not compulsory. Section 15 of the Pilotage Act, 1913, did not, however, come into effect until Jan. 1, 1918, on which date section 633 of the 1894 Act was repealed. The difference which formerly existed under the Merchant Shipping Act, 1894, between British law and the law of most foreign countries as to the civil liability of the owner or master of a vessel employing a pilot under compulsion of law has therefore been removed since Jan. 1, 1918.

See *The Pilotage Act, 1913; Report of Departmental Committee on Pilotage 1911;* Digby & Cole, *Pilotage Law* (1913) (W. J. T. H.)

UNITED STATES

The power of administering all matters relating to pilotage was acquired by the Federal Government as incidental to the authority conferred on it under the Constitution. The first legislative action of the new Government was in 1789, when it delegated its authority to the several States "until further provision is made by Congress." Further legislation enacted subsequently has restricted the broad powers conferred in 1789, but the power of the Federal Government is exclusive only when it is exercised. State laws regarding pilotage are operative so long as they are not in conflict with Federal laws.

Among the acts of the Federal Government restricting the manner in which the several States may control pilotage are: laws which apply to pilotage on waters that are boundaries between States, permitting the master of a vessel to employ a pilot licensed by either State to pilot the vessel to or from such port; laws which prohibit discrimination in rates or pilotage as between vessels operating solely between ports in the State and those engaged in interstate traffic; laws which provide that all coastwise seagoing steamships shall be under the control and direction of pilots licensed under Federal authority; and laws which prohibit State pilots from levying pilotage on coastwise seagoing steamships.

Number and Appointment of Pilots.—In many States no maximum or minimum restriction is placed by statute on the number of pilots that may be appointed, the number being left to the discretion of the several pilotage authorities. In some cases both a maximum and minimum number are prescribed by law and in other States only a maximum number is mentioned. As a rule pilots are licensed by the local pilotage authority, but in several States they are appointed by the governor. In a majority of the States, pilots are licensed for life and lose their licences only because of negligence, incapacity, misconduct or infirmity. In the remaining States licences are granted for periods of one to four years and are renewable. Several grades of licences are generally issued, the grade varying with the draft of vessel which the holder of the licence is considered competent to conduct.

Qualification of Pilots.—In all States the primary qualification for appointment as pilot is actual experience in piloting vessels. A number of States require that applicants for licences as pilots must have served an apprenticeship of a specified number of years on boats of the pilots' association, either in accordance with the law of the State or by regulation of competent authority.

Authority.—In the United States, a pilot occupies the status of an officer of the ship when on board in the exercise of his duty, and his orders as such must be obeyed by the crew. When the master is on board, the orders of the pilot are considered to be those of the master's. The pilot is subject to the master in the matter of discipline but is not liable to any ship's duty except that of pilot. Once in charge of a vessel at sea, it is the duty of the pilot to stay by the ship until she reaches her destination or some place of safety, unless he is earlier discharged.

Liability of Pilots.—Pilots are generally required to give bond, usually $500, to secure the faithful performance of their duties and for the payment of all damages that may accrue from their negligence, unskillfulness or unfaithfulness. The bond is not required in some States, the amount is not specified in the laws of others and in still others it is fixed. The courts have held that while a pilot is responsible to the owner of a vessel for negligence or default in the performance of this duty, he is not liable for the vessel's loss when he has used his best skill and judgment, although the result shows that his best judgment was wrong.

Compulsory Pilotage.—Pilotage is generally compulsory upon certain vessels, or classes of vessels, approaching or departing from a harbour. Throughout the States, all public vessels of the United States and all steamships engaged in the coasting trade are exempt from compulsory pilotage. In respect to other vessels or classes of vessels there is wide variation in the laws of the several States. In the great majority of States compulsory pilotage is prescribed for all vessels, both of domestic and foreign registry, engaged in foreign trade, but not for any class of vessel in the domestic trade. In general the rule is that there has been a tender of the services of a pilot if there has been displayed the customary pilot signal on the usual cruising ground of pilot boats at sea, and there is a visible approach of the boat towards the incoming vessel. If the offer of pilot service is refused, the pilot becomes entitled to full fees or half pilotage, according to the local State law, and the liability for payment is enforceable in admiralty.

Compensation.—In general, pilotage fees are fixed by statute, based on the draught of the vessel. In some cases the rates are prescribed by the local pilotage authorities and the net tonnage of the ship is a factor in determining the pilotage charges. In a number of States where pilotage is compulsory, the full rate is not charged if the services of a pilot are refused. The various statutes commonly provide that pilotage fees are to be paid by and are recoverable from the master or owners of the vessel. In addition to fees for the actual work of pilotage, the statutes of practically every State permit certain extra charges to be made to cover loss of time occasioned by detention of vessel in quarantine or by carrying the pilot to sea when the pilot boat was ready to take him off.

Pilot Boats.—The days when a large number of sailing vessels were in the pilot service off the principal ports, each vessel owned and operated independently, have given way. In 1929 at practically every large port in the United States all of the licensed pilots belong to an association, owning and operating one or more specially constructed steamers which are maintained on the pilotage grounds, usually at the bar. These grounds are well known to mariners, who may safely count on finding there at practically all times a pilot boat displaying the Union Jack, with a sufficient number of pilots aboard to accommodate any reasonable number of vessels seeking to enter the port.

Bibliography.—For legislation on pilotage in the United States, *see* the Revised Statutes and the Statutes at Large of the United States, and the statutes of the several States in which pilot service is maintained, particularly Title 46, U.S. Code; Laws of 1909, New York, Ch. 42, Sec. 56; Revised Laws of Mass., 1902, as amended; Civil Code of 1906, California, Sec. 2036. (C. M. A.)

PILOT-FISH (*Naucrates ductor*), a pelagic fish of the family of horse-mackerels or *Carangidae,* well known to sailors from its habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and subtropical seas, and is common in the Mediterranean. In summer pilot-fish accompany ships into port as far north as the south coast of England. It accompanies both ships and sharks on account of the supply of food which it derives from them, as does the remora (*q.v.*). All observers, however, agree that neither the

pilot-fish nor the sucking-fish is ever attacked by the shark. The pilot attains to a length of about 12in. A sharp keel runs along the middle of each side of the tail. The teeth are small, arranged in bands. On a bluish ground-colour, five to seven dark-blue or violet cross-bands traverse the body from back to belly. The pilot-fish spawns in the open sea.

PILOTY, KARL VON (1826–1886), German painter, born at Munich, on Oct. 1, 1826, was the son of Ferdinand Piloty (d. 1844), noted as a lithographer. His picture of "Seni at the Dead Body of Wallenstein" (1855) soon gained for the young painter the membership of the Munich Academy, where he succeeded Schorn (his brother-in-law) as professor. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany. He was a successful teacher, and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max and Grützner. He died at Munich on July 21, 1886.

PILSEN or PLZEŇ, the second town of Bohemia, Czechoslovakia, at the confluence of the Radbuza and Mze in a fertile and productive fruit and cereal basin. The vicinity is rich in coal and iron. The staple product is beer, exported to all parts of the world, which is closely followed by iron and steel goods and machinery, mainly from the Skoda factory, the greatest in the republic; spirits, leather goods, paper and earthenware are also produced in large quantities. The town is the trade and transport centre for the whole of south-west Bohemia and its cereal and cattle markets are famous.

Little is known of Pilsen till the 10th century and it did not become a town till 1272 but since then it has figured largely in Bohemian history and was a centre of Catholic resistance during the Hussite wars. Among its sights are the 13th century Gothic church with a tower 325 ft. high and a 16th century Renaissance town hall. Pop. (1923) 88,416.

PILSUDSKI, JOSEPH (1867–), Polish soldier and statesman, was born in Nov. 1867 in Zulow (Zulowo), County of Vilna (Wilno) of an ancient family tracing their origin from the Lithuanian Princes of Ginet, and educated at Wilno and Kharkov.

In 1887 Pilsudski was involved in an anti-Tsarist plot and sentenced to five years' penal servitude in Eastern Siberia, although the trial clearly established his innocence and his deprecation of terrorist methods. He returned to Wilno in 1892 and formed the Polish Socialist party (P.S.P.). In 1894 he began the *Robotnik* (The Workman), a secret paper of radical tendencies, edited, printed and distributed by Pilsudski himself. He was already a force. His courage, keen sense of humour, attractive personality and good breeding made him the idol of the working classes; he was revered by the intelligentsia for the tenacity of his convictions, for his fearlessness and his iron will.

His activities increased rapidly. Armed resistance against atrocities of the Russian government was introduced into the party programme. Armed detachments of workmen protected meetings and demonstrations against the police and military, and bloodshed became frequent. In 1900 Pilsudski and his wife, Marie Tuszkiewicz, whom he had married in 1894, were arrested in the offices of the *Robotnik* in Lódz and for a year he was kept in a special cell in the notorious "Tenth Pavilion" of the Warsaw Citadel. Simulating insanity, Pilsudski was transferred to the St. Nicholas Hospital in St. Petersburg, where his friends rescued him by an ingenious plot on May 13, 1901. He lived in London for some time following his escape from imprisonment and returned to Cracow in 1902.

During the Russo-Japanese war Pilsudski planned an insurrection. Frustrated through lack of munitions, he visited Japan to enlist her support, but again proved unsuccessful. After the Russian revolution of 1905 and the convocation of the Duma Polish revolutionary activities were discontinued, but the Russian Constitutional government continued the policy of its predecessors with regard to Poland. Pilsudski transferred his headquarters to Cracow and Lwow and commenced his activities amongst the refugees from the Russian provinces of the country. Here the idea of a "private Polish army" was conceived. An officers' school was established in Lwow and branches of the "sharpshooters" (Strzelec) formed throughout Galicia. Foreseeing the World War, Pilsudski hoped for a German and Austrian victory over Russia and a French victory over Germany. When war broke out, he consequently sided with Austria. The total strength of his "army" was 3,000 infantry and a squadron of cavalry insufficiently armed and equipped; the remaining 7,000 of his men were despatched to Hungary by the Austrian general command. His brigade took part in numerous battles in which it exhibited great bravery and exemplary discipline, while Pilsudski himself displayed the highest qualities as a leader. He refused, however, to let his legions be used outside of Polish territory. On the collapse of Russia, he turned against Germany and Austria. In July 1916 he resigned the command of the Polish legions in consequence of the abuses of the German and Austrian occupation authorities in Polish territory. At the same time he sought to establish relations with France and Great Britain through his colleagues, MM. Sokolnicki and Narutowicz. On Nov. 5, 1916, the independence of Poland was proclaimed by the Central Powers and Pilsudski accepted the position of Minister of War in the newly formed Council of State. Within a short time he formed the semi-secret Polish military organization, *i.e., Polska Organizacia Wojskowa* ("P.O.W."), which spread throughout the country and helped to disarm Germans and Austrians in 1918.

When the Polish legions in Russia, commanded by Gen. Musnicki, proclaimed Pilsudski their spiritual leader, and when his own legions refused, in July 1917, to take the oath of "fraternity of arms with Germany and Austria," Pilsudski was arrested by the Germans and imprisoned with his chief-of-staff Gen. Sosnowski in the fortress of Magdeburg, whence he was released in 1918 by the German revolutionary authorities. He arrived in Warsaw on Nov. 4 and completed the disarmament of the armies of occupation. The Regency Council, established by the Germans, resigned in his favour and all military organizations in the country submitted to his command. He was vested with dictatorial powers, and elected unanimously chief of State, while the army conferred on him the supreme honour of first marshal of Poland.

For Pilsudski's activities during the next years, *see* POLAND. His own chief interest was centred in the army, with which he was very popular, and at the head of which he undertook the campaigns of 1920 in the Ukraine and against the Russian advance on Warsaw. He had, however, many difficulties with other elements in the State and in 1923 he ceased to be chief of State and retired altogether from the army. In May 1926, however, his notorious dislike of the typically-Polish parliamentary wrangling and faction recalled him. He put himself again at the head of the army; a military demonstration on May 12 led to fighting in Warsaw and the resignation of the president. The national assembly, convoked by his successor, M. Rataj, elected Pilsudski president (May 31); but he refused the honour, and became only minister of war, while his friends MM. Masieki and Bartel were elected respectively president and premier. Pilsudski immediately carried through legislation greatly strengthening the position of the president against the parliament; but did not dissolve the latter or establish an open dictatorship, although he constantly prorogued it. In September, indeed, he took over the premiership himself; but seldom appeared in the Sejm, even when it was sitting. The elections of March 1928 gave his adherents a majority. Nevertheless Pilsudski, who had been in bad health, resigned the premiership, retaining, however, the ministry of war, chairmanship of the army council and inspectorate-general of the force. This change made little difference to his position in Poland and the vigorous abuse of the Sejm with which he motivated his actions was not actively resented. For the events of his real, though veiled dictatorship, which was popular in many circles and not aggressive in matters of foreign policy, *see* POLAND.

PIMA, a tribe of Indians on Gila and Salt rivers in southern Arizona, closely related to the Papago, who adjoin them on the south, and to the Pima Bajo in Sonora. They practised irrigation

and lived in permanent though rudely built villages. In their territory are the adobe ruins of Casa Grande and miles of prehistoric ditches. They are divided into five patrilineal totemic groups, make fair pottery and excellent basketry. They differ much from the other sedentary and agricultural natives of the south-west, the Pueblos. Consistently friendly to the whites, they long withstood the Apache courageously, fought back the hostile Yuman tribes, and sheltered those that took refuge with them. Estimated at 2,500 in 1775, they numbered 5,100 in 1921. *See* F. Russell, *Bur. Am. Ethn. Rep.* xxvi. (1908).

The Piman or Sonoran family, now recognized as a division of the larger Uto-Aztecan one, extended from Arizona to Jalisco, Mexico, and included the Pima, Papago, Opata, Tarahumare, Mayo, Yaqui, Tepehuane, Tepecano, Cora, Huichol and other groups. (A. L. K.)

PIMPERNEL (*Anagallis arvensis*), a small herb of the primrose family (Primulaceae), called also shepherd's clock and poor man's weather-glass, native to Europe and widely naturalized in North America from Newfoundland to the Pacific coast and southward to Mexico. It is a delicate annual with diffusely branching stems, with small, opposite, somewhat clasping, leaves, black-dotted beneath, and scarlet (rarely white) flowers, about ½ in. across, usually with a darker centre, opening only in bright sunshine, whence numerous popular names.

PIN, a small peg or bolt of metal or wood, not necessarily pointed, employed as a fastening to connect together different parts of an article, as a stop to limit the motion of some moving piece in a machine, as a support on which a small wheel may turn, etc., but most commonly a small metal spike, used for fastening portions of fabrics together, having one end pointed and at the other a bulbed head, or some other arrangement for preventing the spike from passing entirely through the cloth or other material with which it is employed. In one form or another pins of this last kind are of the highest antiquity, the earliest form doubtless being a natural thorn. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France, and again in 1543 an act was passed providing that "no person shall put to sale any pinnes but only such as shall be double headed, and have the heads soldered fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanched and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626, in which year the manufacture was introduced into Gloucestershire by John Tilsby. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several pin-making machines were invented in the United States. During the War of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836 when the Howe Manufacturing company was formed at Birmingham, Connecticut. Previous to this an American, Lemuel W. Wright, had in 1824 secured in England a patent for a machine to make solid-headed pins, which established the industry on its present basis.

Modern Pin Machinery.—In a modern pin-making machine wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which enough of the end projects to form a pin-head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slit sufficiently wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting extremities are held against a revolving cutter, by which they are pointed.

Then follows the finishing process, which consists of giving the pins the coating of tin which makes them silvery in appearance. In the case of brass pins, they are scoured, cleaned in argol (bitartrate of potash) and water and then tinned in a vat in a solution of water, oxalic acid and granulated tin mixed with the pins at a temperature of 100°C. Iron pins are tinned by an electrolytic process in an alkaline solution of a tin salt. After being washed and dried the pins are polished by being revolved in a barrel, mixed with dry bran or fine sawdust, from which they are winnowed as finished pins. The sizes of ordinary pins range from the 3½-in. stout blanket pin down to the finest slender gilt pin used by entomologists, 4,500 of which weigh about an ounce.

PINACEAE: *see* GYMNOSPERMS.

PINACOTHECA, the Greek name for a picture gallery, apparently reserved in Greece for one that was public, although used by the Romans for a picture gallery in a private house. In modern usage the term usually means the chamber forming the left wing of the Propylaea of the Athenian acropolis, which was used in ancient times as a picture gallery (Pausanias Bk. II., xxii. 6). Various modern public picture galleries bear the same or a similar name, such as those of Bologna and Turin, and at Munich the old and the new Pinakothek.

PINAR DEL RIO, capital of Pinar del Río Province, Cuba, about 107 m. S.W. by railway from Havana. Pop. (1919), 13,728. The city is in the fertile valley of the Guama. It is the centre of the tobacco industry of the Vuelta Abajo region. Its port is La Coloma, on the southern coast. The pueblo was created after 1773; but the history of the settlement goes back to 1571, and the parochial church dates from 1710.

PINCHBECK. When brass, the familiar alloy of copper and zinc, contains 12% to 15% of the latter metal, its colour simulates that of gold. In 1732, a London clockmaker, Christopher Pinchbeck, introduced a brass containing about 15% of zinc for the manufacture of imitation gold jewellery, and the yellow metal bore his name; hence the use of the term "pinchbeck" for flash or imitation jewellery. (*See* BRASS.)

PINCHOT, GIFFORD (1865–), American forester and public official, was born at Simbury, Conn., on Aug. 11, 1865. He graduated at Yale in 1889 and afterwards studied at the École Nationale Forestière, Nancy, France, and for briefer periods in Switzerland, Germany and Austria. Upon his return he began the first systematic forestry work in the United States, in the Vanderbilt forest at Biltmore, N.C. In 1896 he was made a member of the National Forest Commission that worked out the plan of U.S. forest reserves, and in 1897 he became confidential forest agent to the secretary of the Interior, to examine and report upon the reserves. In 1898 he was appointed chief of the division, later the bureau of forestry in the Department of Agriculture, which office he held until 1910. During the period of his administration, the entire forest system and administrative machinery of the bureau was built up, and Pinchot's enthusiasm and publicity work did much for the conservation movement in general. He also served as a member of the committee on public lands, 1903, and the Inland Waterways Commission, 1907. In 1908 he became chairman of the National Conservation Commission, and in 1910 president of the National Conservation Association. He founded the Yale School of Forestry at New Haven, as well as the Yale Summer School of Forestry at Milford, Pa., and in 1903 became professor of forestry at Yale. He was appointed State forester of Pennsylvania in 1920 and began a systematic administration of the large and important forest areas of that State. From 1923 to 1927 he was governor of Pennsylvania, and while in that office forced a reorganization of the State Government and the establishment of a budget system. He was also able, in 1923, to settle an important anthracite coal strike by arbitration.

Besides many articles in magazines, he has written *The White Pine* (1896); *The Adirondack Spruce* (1898); *A Primer of Forestry* (1899);

The Fight for Conservation (1909); *The Training of a Forester* (1917).

PINCKNEY, CHARLES (1757–1824), American statesman, was born on Oct. 26, 1757 at Charleston, S.C.; he was the son of Charles Pinckney (1731–84), first president of the first South Carolina provincial congress (1775), and a cousin of Charles Cotesworth Pinckney and Thomas Pinckney. He was studying law at the outbreak of the Revolutionary War, served in the early campaigns in the South, and in 1779 was elected to the South Carolina house of representatives. He was captured by the British at the fall of Charleston (1780), and remained a prisoner until the close of hostilities. In 1787 he was a delegate to the Federal constitutional convention, and on the same day (May 29) on which Edmund Randolph (*q.v.*) presented what is known as the Virginia plan, Pinckney presented a draft of a constitution which is known as the Pinckney plan Although the Randolph resolutions were made the basis on which the new constitution was framed, Pinckney's plan seems to have been much drawn upon. Furthermore, Pinckney appears to have made valuable suggestions regarding phrasing and matters of detail On Aug. 18, he introduced a series of resolutions, and to him should probably be accredited the authorship of the substance of some 32 or more provisions of the constitution Pinckney was president of the State convention of 1790 that framed a new constitution for South Carolina, was governor of the State 1789–92, a member of the State house of representatives in 1792–1796, and again governor in 1796–98 From 1799 to 1801 he was a member of the United States Senate He entered public life as a Federalist, but later became the leader in organizing the Democratic-Republican party in his State, and contributed largely to the success of Thomas Jefferson in the presidential election of 1800 By Jefferson's appointment he was American minister to Spain from 1801 to 1805 In general his mission was a distinct failure, his arrogance and indiscretions finally causing the Spanish government to request his recall He was again governor of South Carolina in 1806–08, and from 1819 to 1821 was a member of the National House of Representatives, in which he opposed the Missouri Compromise in a brilliant speech. He died at Charleston, S.C., on Oct. 29, 1824.

PINCKNEY, CHARLES COTESWORTH (1746–1825), American statesman, was born in Charleston, S C on Feb 25, 1746, the son of Charles Pinckney (d 1758), a prominent figure in colonial times, by his second wife, the celebrated girl planter, Eliza Lucas When a child he was sent to England, like his brother Thomas after him, to be educated Both of them were at Westminster and Oxford and were called to the bar, and for a time they studied in France at the Royal Military college at Caen Returning to America in 1769, C. C. Pinckney began the practice of law at Charleston He was a member of the first South Carolina provincial congress in 1775, served as colonel in the South Carolina militia in 1776–77, was chosen president of the South Carolina senate in 1779, took part in the Georgia expedition and the attack on Savannah in the same year, was captured at the fall of Charleston in 1780 and kept in confinement until 1782. He was an influential member of the constitutional convention of 1787, advocating the counting of all slaves as a basis of representation and opposing the abolition of the slave-trade He opposed as "impracticable" the election of representatives by popular vote, and also opposed the payment of senators, who, he thought, should be men of wealth Subsequently Pinckney bore a prominent part in securing the ratification of the Federal constitution in the South Carolina convention of 1788. In 1796 he succeeded James Monroe as minister to France. The Directory refused to receive him, and he retired to Holland, but in the next year, Elbridge Gerry and John Marshall having been appointed to act with him, he again repaired to Paris, where he is said to have made the famous reply to a veiled demand for a "loan" (in reality for a gift), "Millions for defence, but not one cent for tribute,"—another version is, "No, not a sixpence." The mission accomplished nothing, and Pinckney and Marshall left France in disgust, Gerry (*q v*) remaining When the correspondence of the commissioners was sent to the United States Congress the letters "X," "Y" and "Z," were inserted in place of the names of the French agents with whom the commission treated—hence the "X Y Z Correspondence," famous in American history. In 1800 he was the Federalist candidate for vice president, and in 1804 and again in 1808 for president, receiving 14 electoral votes in the former and 47 in the latter year. From 1805 until his death, on Aug 16, 1825, he was president general of the Society of the Cincinnati

PINCKNEY, THOMAS (1750–1828), American statesman and diplomat, was born in Charleston, S.C , on Oct 23, 1750, a younger brother of Charles Cotesworth Pinckney (*q v*) Educated in England, he returned to Charleston in 1773, and was admitted to the bar in 1774. During the American Revolution his early training at the French military college at Caen enabled him to render effective service to Gen Benjamin Lincoln, Count d'Estaing and Gen Horatio Gates In the battle of Camden he was badly wounded and captured, remaining a prisoner for more than a year Subsequently he was governor of South Carolina in 1787–89; presided over the State convention which ratified the Federal constitution in 1788; and was United States minister to Great Britain in 1792–96 During part of this time (1794–95) he was also envoy extraordinary to Spain, and in this capacity negotiated (1795) the important Treaty of San Lorenzo el Real; by that treaty the boundary between the United States and East and West Florida and between the United States and "Louisiana" was settled (Spain relinquishing all claims east of the Mississippi above 31° N lat), and the United States secured the freedom of navigation of the Mississippi to its mouth In 1796 Pinckney was the Federalist candidate for vice president, and in 1797–1801 he was a Federalist representative in Congress During the War of 1812 he was a major-general He died in Charleston on Nov 2, 1828 The Pinckneys, like many other South Carolina revolutionary leaders, were of aristocratic birth and politics, closely connected with England by ties of blood, education and business relations This renders the more remarkable their attitude in the American Revolution, for which they made great sacrifices

See C. C. Pinckney, *Life of General Thomas Pinckney* (Boston, 1895).

PIN-CLOVER (*Erodium cicutarium*), an annual herb of the geranium family (Geraniaceae), called also hemlock stork's-bill, and red filaree It is widespread as a weed in the Old World, and is extensively naturalized in North America from Nova Scotia to the Pacific coast, being especially abundant from Texas and Colorado westward to California and Oregon where it is highly esteemed as a forage plant The larger white-stemmed pin-clover, musk clover or filaree (*E moschatus*), native to Europe and locally naturalized in the United States, has become very abundant in California valleys

PINDAR (Gr Πίνδαρος, *c* 522–443 B C), the great lyric poet of ancient Greece was born at Cynoscephalae, in Boeotia, at the time of the Pythian games (*fr* 175, Bergk[4], 193)[1], which is taken by Bockh to be 522 B C He would thus be some thirty-four years younger than Simonides of Ceos He was the son of Daiphantus and Cleodice (or Cleidice) The clan of the Aegidae—tracing their line from the hero Aegeus—belonged to the "Cadmean" element of Thebes, *i e* , to the elder nobility whose supposed date went back to the days of the founder Cadmus Pindar stood, that is, within the circle of those families for whom the heroic myths were domestic records He had a personal link with the memories which everywhere were most cherished by Dorians, no less than with those which appealed to men of "Cadmean or of Achaean stock And the wide ramifications of the Aegidae throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic

Life.—Pindar is said to have received lessons in flute-playing from one Scopelinus at Thebes, and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his profuse employment of Theban mythology, is

[1]The references are to the edition of Pindar by C. A M Fennell (1893–99), and the fourth edition of Bergk's *Poetae lyrici graeci*.

said to have advised him "to sow with the hand, not with the sack." There is an extant fragment in which Corinna reproves another Theban poetess, Myrtis, "for that she, a woman, contended with Pindar" (ὅτι βανὰ φοῦσ' ἔβα Πινδάροιο ποτ' ἔριν) —a sentiment which hardly fits the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was, indeed, indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music, and in the adaptation of both to the intricate movements of the choral dance (ὀρχηστική).

Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time, and at the various elements of art which the lyrist was required to temper into a harmonious whole (*see*, e.g., *Ol.* iii. 8, vi. 91, xiii. 18, xiv. 15; *Pyth.* xii. 23, etc.). The earliest ode which can be dated (*Pyth.* x.) belongs to the twentieth year of Pindar's age (502 B.C.); the latest (*Olymp.* v.) to the seventieth (452 B.C.)[1]. He visited the court of Hiero at Syracuse; Theron, the despot of Acragas, also entertained him; and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi: "He was greatly honoured by all the Greeks, because he was so beloved of Apollo that he even received a share of the offerings; and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god"[2]. His wife's name was Megacleia (another account says Timoxena, but this may have been a second wife), and he had a son named Daiphantus and two daughters, Eumetis and Protomache. He is said to have died at Argos, at the age of seventy-nine, in 443 B.C.

Piety.—Among the Greeks of his own and later times Pindar was pre-eminently distinguished for his piety towards the gods. He tells us that, "near to the vestibule" of his house (*Pyth.* iii. 78), choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the phrygian music of the flute, in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele, which he dedicated at Thebes, were the work of the Theban artists, Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios, and another, by Calamis, to Zeus Ammon. The latter god claimed his especial veneration because Cyrene, one of the homes of his Aegid ancestry, stood "where Zeus Ammon hath his seat," *i.e.*, near the oasis and temple (*Pyth.* iv. 16). The author of one of the Greek lives of Pindar says that, "when Pausanias the king of the Lacedaemonians was burning Thebes, some one wrote on Pindar's house. 'Burn not the house of Pindar the poet'; and thus it alone escaped destruction." This incident, of which the occasion is not further defined, has been regarded as a later invention[3].

Better attested, at least, is the similar clemency of Alexander the Great, when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia, or citadel, of Thebes (thenceforth to be occupied by a Macedonian garrison); (2) the temples and holy places; and (3) Pindar's house. While the inhabitants were sold into slavery, exception was made only of (1) priests and priestesses; (2) persons who had been connected by private ξενία with Philip or Alexander, or by public ξενία with the Macedonians; (3) Pindar's descendants. It is probable enough, as Dio Chrysostom suggests (ii. 33), that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I. of Macedon. But he must have been also, or chiefly, influenced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory, not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods, and, above all, to the Delphian Apollo.

Praise of Athens.—During the second half of Pindar's life, Athens was rising to that supremacy in literature and art which was to prove more lasting than her political primacy. Pindar did not live to see the Parthenon, or to witness the mature triumphs of Sophocles; but he knew the sculpture of Calamis, and he may have known the masterpieces of Aeschylus. It is interesting to note the feeling of this great Theban poet, who stands midway between Homeric epos and Athenian drama, towards the Athens of which Thebes was so often the bitterest foe, but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those "sons of Athens" who "laid the shining foundations of freedom" (παῖδες 'Αθαναίων ἐβάλοντο φαεννὰν κρηπῖδ' ἐλευθερίας, *fr.* 55, Bergk^4, 77), while Athens itself is thus invoked: ὦ ταὶ λιπαραὶ καὶ ἰοστέφανοι καὶ ἀοίδιμοι, 'Ελλάδος ἔρεισμα, κλειταὶ 'Αθᾶναι, δαιμόνιον πτολίεθρον (fr. 54, Bergk^4, 76). Isocrates, writing in 353 B.C., states that the phrase 'Ελλάδος ἔρεισμα, "stay of Hellas," so greatly gratified the Athenians that they conferred on Pindar the high distinction of προξενία (*i.e.*, appointed him honorary consul, as it were—for Athens at Thebes), besides presenting him with a sum of money (*Antidosis*, 166).

One of the letters of the pseudo-Aeschines (*Ep.* iv.) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens, and that the Athenians repaid him twice the sum[4]. The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens, near the temple of Ares (i. 8, 4). Besides the fragment just mentioned, several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars, while he gives the glory of Plataea to the Spartans, he assigns that of Salamis to the Athenians (*Pyth.* i. 76). In celebrating (*Pyth.* vii.) the Pythian victory of the Athenian Megacles, he begins thus: "Fairest of preludes is the renown of Athens for the mighty race of the Alcmaeonidae. What home, or what house, could I call mine by a name that should sound more glorious for Hellas to hear?" (*Cf.* also *Nem.* v. 49.)

Pindar's versatility as a lyric poet is one of the characteristics remarked by Horace (*Odes*, iv. 2), and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Epinicia*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied.

Fragments.—(1) Ὕμνοι, *Hymns* to deities—as to Zeus Ammon, to Persephone, to Fortune. The fragmentary ὕμνος entitled Θηβαίοις seems to have celebrated the deities of Thebes. (2) Παιᾶνες, *paeans*, expressing prayer or praise for the help of a protecting god, especially Apollo, Artemis or Zeus. (3) Διθύραμβοι, *Dithyrambs*, odes of a lofty and impassioned strain, sung by choruses in honour of Dionysus. (4) Προσόδια, *Processional Songs*, choral chants for worshippers approaching a shrine. (5) Παρθένια, *Choral Songs for Maidens.*

(6) Ὑπορχήματα, *Choral Dance-Songs*, adapted to a lively movement, used from an early date in the cult of Apollo, and afterwards in that of other gods, especially Dionysus. To this class belongs one of the finest fragments (84, Bergk^4, 107), written for the Thebans in connection with propitiatory rites after an eclipse of the sun, probably that of the 30th of April 463 B.C. (7) 'Εγκώμια, *Songs of Praise* (for men, while ὕμνοι were for gods), to be sung by a festal company. (8) Σκόλια, *Festal Songs.* The usual sense of σκόλιον is a drinking-song, taken up by one guest after another at a banquet. But Pindar's σκόλια were choral and antistrophic. One was to be sung at Corinth by a chorus of the ἱερόδουλοι attached to the temple of Aphrodite Ourania, when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment, for Theoxenus of Tenedos, has an erotic character.

(9) Θρῆνοι, *Dirges*, to be sung with choral dance and the music of the flute, either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class

[1]According to others, his latest poem is the eighth Pythian ode, 450 or 446.

[2] Πινδάρου γένος, in ed. Ald.

[4]Compare Jebb, *Attic Orators*, ii. 143.

(106–110, Bergk[4], 129–133). A number of small fragments, which cannot be certainly classified, are usually given as ἐξ ἀδήλων εἰδῶν, "of uncertain class."

The Epinicia.—The ἐπινίκια (*sc.* μέλη), or ἐπινίκιοι (*sc.* ὕμνοι), "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to the four great festivals: (1) Ὀλυμπιονῖκαι (*sc.* ὕμνοι): fourteen odes for winners of the wild olive-wreath in the Olympian games, held at Olympia in honour of Zeus once in four years; (2) Πυθιονῖκαι: twelve odes for winners of the laurel-wreath in the Pythian games held at Delphi in honour of Apollo, once in four years, the third of each Olympiad; (3) Νεμεονῖκαι: eleven odes for winners of the pine-wreath in the Nemean games, held at Nemea, in honour of Zeus, once in two years, the second and fourth of each Olympiad; and (4) Ἰσθμιονῖκαι: seven odes for winners of the parsley wreath in the Isthmian games, held at the Isthmus of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympiad. The Greek way of citing an ode is by the nomin. *plur.* followed by the numeral, *e.g.*, "the ninth Olympian" is Ὀλυμπιονῖκαι θ' The chronological range of the collection (so far as ascertainable) is 502 B.C. (*Pyth.* x.) to 452 B.C. (*Ol.* v.).

The general characteristics of the odes may be briefly considered under the following heads: (1) language; (2) treatment of theme; (3) sentiment—religious, moral and political; (4) relation to contemporary art.

Diction.—The diction of Pindar is distinct in character from that of every other Greek poet, being almost everywhere marked by the greatest imaginative boldness Thus (*a*) metaphor is used even for the expression of common ideas, or the translation of familiar phrases, as when a cloak is called (*Ol.* ix. 97) "a warm remedy for winds." (*b*) Images for the highest excellence are drawn from the farthest limits of travel or navigation, or from the fairest of natural objects, as when the superlative hospitality of a man who kept open house all the year round is described by saying, "far as to Phasis was his voyage in summer days, and in winter to the shores of Nile" (*Isthm.* ii. 41); or when Olympia, the "crown" or "flower" of festivals, is said to be excellent as water, bright as gold, brilliant as the noonday sun (*Ol* i *ad init*). This trait might be called *the Pindaric imagery of the superlative.* (*c*) Poetical inversion of ordinary phrase is frequent; as, instead of, "he struck fear into the beasts," "he gave the beasts to fear" (*Pyth.* v. 56) (*d*) The efforts of the poet's genius are represented under an extraordinary number of similitudes, borrowed from javelin-throwing, chariot-driving, leaping, rowing, sailing, ploughing, building, shooting with the bow, sharpening a knife on a whetstone, mixing wine in a bowl, and many more. (*e*) Homely images, from common life, are not rare; as from account-keeping, usury, sending merchandise over sea, the σκυτάλη or secret dispatch, etc. And we have such homely proverbs as, "he hath his foot in this shoe," *i.e.*, stands in this case (*Ol.* vi 8). (*f*) The natural order of words in a sentence is often boldly deranged, while, on the other hand, the syntax is seldom difficult. (*g*) Words not found except in Pindar are numerous, many of these being compounds which (like ἐναρίμβροτος, καταφυλλοροεῖν, etc) suited the dactylic metres in their Pindaric combinations Horace was right in speaking of Pindar's "nova verba," though they were not confined to the "audaces dithyrambi."

Subjects.—The actual victory which gave occasion for the ode is seldom treated at length or in detail—which, indeed, only exceptional incidents could justify. Pindar's method is to take some heroic myth, or group of myths, connected with the victor's city or family, and, after a brief prelude, to enter on this, returning at the close, as a rule, to the subject of the victor's merit or good fortune, and interspersing the whole with moral comment. Thus the fourth Pythian is for Arcesilaus, king of Cyrene, which was said to have been founded by men of Thera, descendants of one of Jason's comrades. Using this link, Pindar introduces his splendid narrative of the Argonauts. Many odes, again, contain shorter mythical episodes—as the birth of Iamus (*Ol.* vi), or the vision of Bellerophon (*Ol.* xiii.)—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical digression to his immediate theme. It is bold and swift, yet is not felt as harshly abrupt—justifying his own phrase at one such turn—καί τινα οἶμον ἴσαμι βραχύν (*Pyth.* iv. 247).

Religious, Moral and Political Sentiment.—*a.* The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence." He will not believe that the gods, when they dined with Tantalus, ate his son Pelops; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, viz., that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as *Ol.* ii. 66 *seq.*). Pindar was familiar with the idea of metempsychosis (cf. *ibid.* 68), but the attempt to trace Pythagoreanism in some phrases (*Pyth.* ii. 34, iii. 74) appears unsafe. The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the Θρῆνος (114, Bergk[4], 137), we may probably regard the esoteric element in Pindar's theology as due to such a source.

b. The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (φυή) is the grand source of all human excellence (ἀρετή), while such excellences as can be acquired by study (διδακταὶ ἀρεταί, *Ol.* ix. 100) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other The elements of ὑγιεὶς ὄλβος—"sane happiness," such as has least reason to dread the jealousy of the gods—are substance sufficing for daily wants and good repute (εὐλογία). He who has these should not "seek to be a god" "Wealth set with virtues" (πλοῦτος ἀρεταῖς δεδαιδαλμένος), as gold with precious gems, is the most fortunate lot, *because* it affords the amplest opportunities for honourable activity Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate thy foe" (cf. *Pyth.* ii. 83; *Isthm* iii 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of generous emulation and of reverent self-control.

c. The political sentiments of the Theban poet are suggested by *Pyth* xi. 52; "In polities I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in *Pyth* ii. 87, a democracy is described as ὁ λάβρος στρατός, "the raging crowd," it is to be noted that the ode is for Hiero of Syracuse, and that the phrase clearly refers to the violence of those democratic revolutions which, in the early part of the 5th century B C , more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (ὀλιγαρχία ἰσόνομος, Thuc. iii 62) had replaced the narrower and less temperate oligarchy of former days (δυναστεία οὐ μετὰ νόμων); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (*Ol.* i. 113); he sketches the character of an ideal king (*Pyth.* iii. 71); but nothing in his poetry implies liking for the τυραννίς as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence, he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars He honours "Tranquillity, the friend of cities" (Ἁσυχία φιλόπολις, *Ol* iv. 16). The epic poet sang of wars: Pindar celebrates the "rivalries of peace."

Love of Natural Art.—Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent

new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (*Ol.* ix. 80). Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase δαιδάλλειν, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (*Ol.* vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the hours is opened, and delicate plants perceive the fragrant spring" (*fr.* 53, Bergk[4], 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (*Pyth.* iv. 195); in the lines on the eclipse of the sun (*fr.* 84, Bergk[4], 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (*Pyth.* i. 20). The poet's feeling for colour is often noticeable—as in the beautiful story of the birth of Iamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (*Ol.* vi. 55).

Relation to Art.—The spirit of art, in every form, is represented for Pindar by χάρις—"the source of all delights to mortals" (*Ol.* i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty. The period from 500 to 460 B.C., to which most of Pindar's extant odes belonged, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina were effecting a transition from archaic types to the art which was afterwards matured in the age of Pheidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards sculpture had been applied to the commemoration of athletes, chiefly at Olympia.

In a striking passage (*Nem.* v. *ad. init.*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Aegina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithae, and (6) a contest between Heracles and Apollo, are instances of mythical material treated alike by the poet and by sculptors of his day.

Place in Greek Literature.—In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians, Alcman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as *die universalen Meliker.* The Greeks usually spoke, not of "lyric," but of "melic" poetry (*i.e.*, meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyrist. Epic, lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth.

In Pindar we can see that phase of the Greek mind which produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth.* iv.), the meeting of Apollo and Chiron (*Pyth.* ix.), the episode of Castor and Polydeuces (*Nem.* x.), the entertainment of Heracles by Telamon (*Isthm.* v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Aeschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

The fact that certain glosses and lacunae are common to all our mss. of Pindar make it probable that these mss. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymus (*c.* 15 B.C.), sometimes presuppose a purer text than ours. But the compiler of these older scholia lived after Herodian (A.D. 160). The archetype of our mss., then, cannot have been older than the end of the 2nd century. Our mss. fall into two general classes: (1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit the traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in *Pyth.* v.; Ambrosianus 1, which has only *Ol.* i.–xii.; Mediceus 2; and Vaticanus 2—the two last-named being of the highest value. The editio princeps is the Aldine (Venice, 1513). A modern study of Pindar may be almost said to have begun with C. G. Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But August Böckh (1811–21), who was assisted in his commentary by L. Dissen, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (*Poetae lyrici graeci,* 1878 new ed. by O. Schröder, 1900) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to mss. A recension by W. Christ has been published in Teubner's series (2nd ed., 1896), also with Prolegomena and commentary (1896); and by O. Schröder (1908). The complete edition of J. W. Donaldson (1841) has many merits; but that of C. A. M. Fennell (1879–83; new ed., 1893–99) is better adapted to the needs of English students. The *Olympia* and *Pythia* have been edited by B. L. Gildersleeve (1885), the *Nemea* and *Isthmia* by J. B. Bury (1890–92); the *Scholia* by E. Abel (1890, unfinished) and A. B. Brachmann (1903). There is a special lexicon by J. Rumpel (1883). The translation into English prose by Ernest Myers (2nd ed., 1883) is excellent; verse translation by T. C. Baring (1875), and of the *Olympian Odes* by Cyril Mayne (1906), also the edition in the *Loeb Classical Library,* with Eng. trans. by J. Sandys (1915). Pindar's metres have been analysed by J. H. H. Schmidt, *Die Kunstformen der griechischen Poesie* (Leipzig, 1868–72). On Pindar generally, *see* L. Schmidt, *Pindar's Leben und Dichtung* (1862); F. D. Morice, *Pindar* (1879); A. Croiset, *La Poésie de Pindare* (1880); G. Lübbert, *Pindar's Leben und Dichtungen* (Bonn, 1882); W. Christ, *Geschichte der griechischen Litteratur* (1898); F. Dornseiff, *Pindars Stil* (1921). Bibliographical information on the earlier literature will be found in W. Engelmann, *Scriptores graeci* (1881); *see* also L. Bornemann, in *Jahresbericht über die Fortschrift der classischen Altertumswissenschaft* (ed. C. Bursian, vol. cxvi., 1904), with special reference to chronological questions and *Pythia,* i., ii., iii. Some considerable fragments of the paeans were discovered in 1906 by B. P. Grenfell and A. S. Hunt, see *Paeans* in *Oxyrhynchus papyri* (pt. v. 1908), and A. E. Housman, in *Classical Review* (Feb. 1908).

(R. C. J.; X.)

PINDARICS, the name by which was known a class of loose and irregular odes in fashion in England during the close of the 17th and the beginning of the 18th century. The invention is due to Abraham Cowley, who, probably in Paris, and perhaps in 1650, found a text of Pindar and determined to imitate the Greek poetry in English, without having comprehended the system upon which Pindar's prosody was built up. Cowley published, in 1656, 15 *Pindarique Odes,* which became the model on which countless imitators founded their pindarics. The erroneous form of these poems, which were absolutely without discipline of structure, was first exposed by Congreve, exactly half a century later. The laxity of these "pindarics" attracted the poets of the unlyrical close of the 17th century, and they served the purpose not only of Dryden and Pope, but of a score of lesser poets. Although the vogue of these forms hardly survived the age of Anne, something of the vicious tradition of them still remained, and even in the

odes of Wordsworth, Shelley and Coleridge the broken versification of Cowley's pindarics occasionally survives.

PINDARIS, a word of uncertain origin, applied to the irregular horsemen who accompanied the Mahratta armies in India during the 18th century. They received no pay, but rather purchased the privilege of plundering on their own account. The majority of them seem to have been Mohammedans. When the regular forces of the Mahrattas had been broken up in the campaigns conducted by Sir Arthur Wellesley and Lord Lake in 1802–4, the Pindaris made their headquarters in Malwa, under the tacit protection of Sindhia and Holkar. They usually assembled annually in November to set forth over British territory in search of plunder. In 1808–9 they plundered Gujarat, and in 1812 Mirzapur. In 1814 they were reckoned at 25,000 to 30,000 horsemen, half of them well armed In 1817 the marquess of Hastings obtained the consent of the East India Company to the organized campaign, known as the Pindari War. The Pindaris were surrounded on all sides by a great army, consisting of 120,000 men and 300 guns: and Sindhia, overawed, was forced to sign the treaty of Gwalior, consenting to aid in the extirpation of the Pindaris, whom he had hitherto protected The Peshwa at Poona, the Bhonsla raja at Nagpur and the army of the infant Holkar each took up arms, but were separately defeated The Pindaris themselves offered little opposition. Amir Khan, their most powerful leader, accepted the conditions offered to him His descendant is now Nawab of the state of Tonk in Rajputana

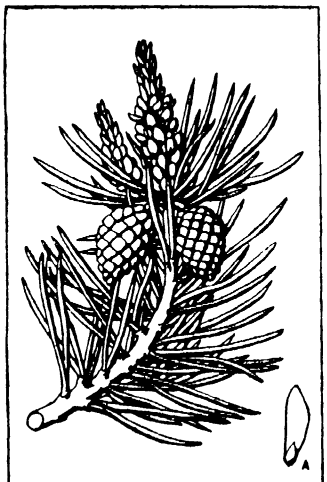
See J Grant Duff, *History of the Mahrattas* (1826); and Major Ross of Bladensburg, *Marquess of Hastings* (Rulers of India Series) (1893).

PINDUS, the ancient name for the mountains which separate Thessaly from Epirus, often used by modern geographers in a somewhat extended sense The folded Alpine chains are continued down the western coast of the Balkan peninsula, where in the north they form the Dinaric Alps In the neighbourhood of Scutari (Skadar), however, the direction of the coast-line undergoes a marked change, associated with a change in the trend of the mountain folds In the extended sense the name Pindus is applied to the chain of fold-mountains which extends from the Šar Planina, in the latitude of Scutari, southwards to about the latitude of the Gulf of Arta, and thus includes most of the mountains of Albania. As a rule massive limestones are less developed in the Pindus than in the Dinaric region, so that the karstic type of landscape is less frequent and less repellent than in the north, the prevailing types of rocks being often schists, grits and greenish eruptive rocks, especially serpentines The range rises to a maximum height of about 8,000 feet, and in places the original forests, mainly of oak and beech, have been preserved

PINE, a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied, and, as limited by modern botanists, the designation of a large genus (*Pinus*) of true conifers, differing from the firs in their hard woody cone-scales being thickened at the apex, and in their slender needle-shaped leaves growing from a membranous sheath, either in pairs or from three to five together—each tuft representing an abortive branch, springing from the axil of a partially deciduous scale-leaf, the base of which remains closely adherent to the stem The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots; the anther-scales, surmounted by a crest-like appendage, shed their abundant pollen by longitudinal slits; the two ovules at the base of the inner side of each fertile cone-scale develop into a pair of winged seeds, which drop from the opening scales when mature

The pines, which comprise about 70 species, are widely distributed over the north temperate zone, in the southern portions chiefly confined to the mountains, along which, in Central America, a few are found within the Tropics; in more northern regions they frequently form extensive forests, sometimes hardly mingled with other trees. One species occurs native in Great Britain; about 30 are indigenous to the United States and Canada Their soft, straight-grained, resinous and often durable wood gives to many kinds a high economic value, and some are among the most esteemed of timber trees.

Of the two-leaved species, *P. sylvestris,* the pine of northern Europe, may be taken as a type. When growing in perfection it is one of the finest of the group, and perhaps the most picturesque of forest trees; attaining a height of from 70 to 120 ft., it is of conical growth when young, but in maturity acquires a spreading cedar or mushroom-like top, with a straight trunk, two to four feet in diameter at the base, and gnarled twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often twisted; the male catkins, in dense cylindrical whorls, fill the air of the forest with their sulphur-like pollen in May or June, and pollinate the purple female flowers, which, at first sessile and erect, then become recurved on a lengthening stalk, the ovate cones, about the length of the leaves, are not fertilized until the next summer and do not reach maturity until the autumn of the following year They seldom open and scatter their seeds until the third year *P. sylvestris* is found, in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest-slopes of Etna, while in longitude its range extends from the shores of the North Sea to Kamchatka Nowhere more abundant than in the Scandinavian peninsula, this tree is the true fir (*fur, fura*) of the old Norsemen, and still retains the name in Great Britain, though botanically now classed as a pine It grows vigorously in Lapland on the lower ground, while in south Norway it occurs up to 3,000 ft, though the great forests from which "Norway pine" timber is chiefly derived are on the comparatively lower slopes of the south-eastern dales: in the highest situations it dwindles to a mere bush It furnishes the yellow deal of the Baltic and Norway In Germany, both on the mountains and the sandy plains woods of "kiefer" are frequent and widely spread, while vast forests in Russia and Poland are chiefly composed of this species; in many northern habitats it is associated with the spruce and birch In Asia it abounds in Siberia and on the mountains of the Amur region, on the European Alps it occurs at a height of 5,600 ft, and on the Pyrenees it is found at still higher elevations In Great Britain natural forests of Scotch fir of any extent are only now found in the Highlands, chiefly on the declivities of the Grampians The tree is not at present indigenous in southern Britain, but when planted in suitable ground multiplies rapidly by the wind-sown seeds; on many of the sandy moors and commons natural pine woods of large extent have been thus formed during recent years The heartwood of the finer kinds of Scotch fir is of a deep brownish-red colour, abounding in the resin to which its durability is probably due For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking is perhaps little inferior; from its lightness and elasticity it is well adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from 30 to 40 lb per cubic foot Great numbers of young pines are annually cut for railway sleepers, mining timber and numerous agricultural applications; large quantities are consumed for wood-pavement The quality of the timber depends greatly on the soil and position in which the trees are grown The rapidity of growth is still more variable in Britain full maturity is attained in from 70 to 120 years, but in Norway the trunk increases much more slowly; Schubeler states that a tree felled in the Alten district (about 70° lat), measuring 2 ft 10 in in diameter, showed 400 annual rings



SCOTCH FIR (PINUS SYLVESTRIS)
Branch with male flowers above, young cones below, (A) winged seed

In the economy of the northern nations of Europe *P. sylvestris* is an important tree. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, in times of scarcity, is kiln-dried, ground up and mixed with meal.

Vast numbers of Scotch firs are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct to the seed-bed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of young Scotch firs requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, except for the removal of dead wood.

In Great Britain *P. sylvestris* is subject to many insect depredations: the pine-chafer, *Hylurgus piniperda,* is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; the fir-weevil, *Hylobius abietis,* eats away the bark, and numerous lepidopterous larvae devour the leaves; the pine-sawfly is also injurious in some seasons. The removal of all dead branches from the trees and from the ground beneath them is recommended, as most of these insects lay their eggs in the decaying parts of the bark and among the dead leaves.

In common with other pines, *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem, causing rotting of the wood. The disease is difficult to eradicate, as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus,* which spreads in the soil by means of its long purple-black, cord-like mycelial strands known as *Rhizomorpha.* Much damage is often caused by species of *Peridermium,* which often invade the soft portions of the inner bark to such an extent as to "ring" the stem or branch, or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water; this causes the parts above the diseased area to perish.

Plantations in England are generally ready for final cutting in from 60 to 70 years, and many are cleared at a much earlier stage of growth, especially when protected from injury by pests. In England the pine is largely employed as a "nurse" for oak trees, its conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species. This pine is planted for ornament in the Eastern United States where it has become sparingly naturalized; it has also proved of value in afforesting treeless lands, as in the National forest in western Nebraska.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. Pumilio,* the "krummholz" or "knieholz" of the Germans—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir, but is shorter, denser and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tirolese Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit.

The red pine, *P. resinosa,* of south-eastern Canada and the northern border of the United States from Minnesota eastward (so called from the colour of its bark), is a tree sometimes 120 ft. high, with a trunk 3 ft. or more in diameter. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir although much employed in shipbuilding.

P. Laricio, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 in. long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish-tint. In southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils. The black pine, *P. austriaca,* generally now regarded as a variety of *P. Laricio,* derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree.

P. Pinaster, the cluster or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand. and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds (pignons), which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid.

Nearly approaching this is *P. excelsa,* the Bhotan or blue pine, which differs chiefly in its longer cones and drooping glaucous foliage. It is found in Kumaon and Bhotan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 7,000 to 12,000 ft., and attains large dimensions.

P. Cembra is the stone pine of Siberia and central Europe. It abounds on the Alps, the Carpathians and the Siberian ranges, in Switzerland being found at an altitude of 4,000 to 6,000 ft. The seeds are oily like those of *P. Pinea,* and are eaten both on the Alps and by the inhabitants of Siberia; a fine oil is expressed

from them which is used both for food and in lamps. The growth of *P. Cembra* is slow, but the wood is of remarkably even grain, and is employed by the Swiss wood-carvers in preference to any other. Numerous species of pine are planted for ornament, afforestation, and timber production.

North American Pines.—The 35 or more species and major varieties of pine native to North America north of Mexico may be grouped in two sections, the *soft pines* and the *pitch pines.*

The *soft pines* have soft, close-grained wood, with thin nearly white sapwood; the sheaths of the leaf-clusters fall off early (deciduous); the leaves contain a single fibro-vascular bundle, and, excepting those of the nut pines, the leaves are in five-leaved clusters.

There are 11 species, only one of which, the eastern white pine, is found east of the Great Plains, the others occurring in the Rocky-Mountain region and on the Pacific coast.

The soft pines consist of four groups. (1) the *white pines,* large trees with long-stalked, thin-scaled, cylindrical cones, including the eastern white pine (*P. Strobus*), the western white pine (*P. monticola*) and the sugar pine (*P. Lambertiana*); (2) the *stone pines,* medium-sized trees with short-stalked, thick-scaled cones, including the limber pine (*P. flexilis*) and the whitebark pine (*P. albicaulis*); (3) the *foxtail pines,* rather small trees with short-stalked, ovoid, prickly cones, including the foxtail pine (*P. Balfouriana*) and the bristle-cone pine (*P. aristata*); and (4) the *nut pines,* small trees with leaves in one- to four-leaved clusters, globose cones and large edible seeds, including the piñon (*P. edulis*), the single-leaf piñon (*P. monophylla*), the Parry piñon (*P Parryana*) and the Mexican piñon (*P. cembroides*) By some authorities *P. edulis, P. monophylla* and *P. Parryana* are regarded as varieties of *P. cembroides.*

The eastern white pine, *P. Strobus*, known also as Weymouth pine, because of its large growth and soft even grain of its white wood, is one of the most valuable of North American timber trees It once formed extensive forests from Newfoundland to Manitoba and along the northern border of the United States from Maine to Minnesota and also southward in the mountains to Georgia but it has been so long sought for by the lumberer that most of the old trees have long disappeared On a deep rich soil *P Strobus* sometimes attains a height of 200 ft., and a trunk diameter of 4 to 6 feet The wood of the white pine is durable for indoor use, especially when protected by paint, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner. The western white pine, *P. monticola*, a mountain species of the north-western United States and British Columbia, with light brown wood, is extensively cut for lumber, especially in Idaho

The sugar pine or giant pine, *P Lambertiana,* of California, the largest of known pines, rises to a height of 200 ft. to 220 ft., with a trunk from 6 ft to 8 ft, or occasionally 12 ft in diameter The head is of a pyramidal form, the lower branches drooping like those of a Norway spruce, its foliage is of a light bright green colour The pendent cones are very large, sometimes 18 in long and 4 in in diameter, with large nut-like seeds, which, pounded and baked, are eaten by the Indians It is lumbered extensively, the wood being highly valued for indoor carpentry.

The *pitch pines* have usually heavy, coarse-grained, mostly dark-coloured wood, with pale often thick sapwood, the sheaths of the leaf-clusters are persistent (except in the Chihuahua pine), the leaves have two fibro-vascular bundles, and are arranged mostly in three-leaved and two-leaved clusters There are some 24 species about equally divided in number between the region east of the Great Plains and the region extending from the Rocky Mountains to the Pacific coast.

The group of pitch pines with the leaves usually in three-leaved clusters includes several of the most valuable trees of North America. Among these are the longleaf pine (*P. palustris*), the slash pine (*P. caribaea*), the loblolly pine (*P. Taeda*), the pitch pine (*P. rigida*) and the pond pine (*P serotina*), of the southern States, and the western yellow pine (*P. ponderosa*), the Jeffrey pine (*P. Jeffreyi*) and the Arizona pine (*P. arizonica*), of the Pacific States. Other representatives of the three-leaved group are the Monterey pine (*P. radiata*), the knob-cone pine (*P. attenuata*), the digger pine (*P. Sabiniana*) and the Coulter pine (*P. Coulteri*), of California and Oregon, and also the Chihuahua pine (*P leiophylla*) of the Mexican border.

The group of pitch pines with leaves usually in two-leaved clusters also comprises several important trees. Among these are the red or Norway pine (*P. resinosa*), the grey or jack pine (*P Banksiana*), the spruce pine (*P. glabra*), the shortleaf pine (*P echinata*), the Virginia pine (*P. virginiana*), the sand pine (*P. clausa*) and the mountain pine (*P. pungens*), of the region east of the Rocky Mountains. Here belong also the lodge-pole pine (*P contorta*), found from New Mexico to Alaska, and the knob-cone pine (*P attenuata*), of California and Oregon. Other representatives of the two-leaved group are the bishop pine (*P. muricata*) and the rare Torrey pine (*P. Torreyana*), both confined to the California coast.

Long-leaf pine (*P. palustris*) is the "Georgia pitch pine," or yellow pine of the southern States; it abounds on sandy soils from the Carolinas, and Florida westward to Louisiana and Texas The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length The tall columnar trunk, sometimes 120 ft high furnishes one of the most valued pine timbers of the United States, close-grained and resinous, it is very durable and polishes well, it is largely employed in construction work, and large quantities are exported, especially to Great Britain and the West Indies This tree is the chief lumber-producing pine of the southern United States; it also yields large quantities of tar and turpentine

The loblolly pine, *P. Taeda,* a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern States, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming, hence the woodsmen call it the "old-field" pine while, from the fragrance of its abundant resin, it is also known as the frankincense pine It is a fine species 80 to 100 ft high, having sometimes a girth of 6 or 8 ft The timber of this pine, though soft and brittle, is much used for lumber and the forests of it are of importance because of the turpentine they yield

The western yellow pine or bull pine, *P. ponderosa,* which grows from 150 ft to 200 ft high, with a massive trunk 5 ft to 8 ft in diameter, is noted for the extreme density of its wood, which barely floats in water, it is the most widely distributed pine tree of the mountain forests of western North America from British Columbia to South Dakota (Black Hills) and south to Texas and Mexico It is the chief lumber pine of the Pacific States, where it is second in importance only to the Douglas fir (*q v*) The Coulter pine, *P Coulteri,* is remarkable for its enormous cones (sometimes a foot long, 6 in in diameter, and weighing more than 4 lb), the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is the digger pine, *P Sabiniana,* of California, the cones of which are 7 to 9 in long and 5 to 6 in in diameter, also with hooked scales, the large nut-like seeds are eaten by the Indians; the tree sometimes attains a height of 80 ft and a trunk diameter of 4 feet The beautiful Monterey pine, *P radiata,* found sparingly along the California coast, is distinguished by the brilliant colour of its foliage The Torrey pine, *P Torreyana,* with leaves 12 in. long, found only in a narrow strip some 8 m. in length, along the coast near San Diego, Calif, and on Santa Barbara island, is the least widely distributed of all known pines.

The pitch pine, *P rigida,* found from the coast of Massachusetts south-westward throughout the Appalachian region, is a tree of from 40 to 50 ft in height with rugged trunk, occasionally 3 ft in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes

Pine Lumbering in the United States.—The various native species of pine, several of which form forests of vast extent, constitute the chief source of the soft-wood (coniferous) lumber

produced in the United States. According to the census of manufactures the total cut in 1925 of both soft-wood and hard-wood lumber was 38,338,614,000 bd. ft.; this had an aggregate value at the mill of $1,074,248,000. Of this total there was cut from pine trees an aggregate of 18,191,284,000 bd. ft., valued at the mill at $500,660,114. The pine forests of the country, therefore, contributed 47·5% of the footage and 46·6% of the value of all lumber produced. For the same year the total cut of soft-wood lumber was 31,686,919,000 bd. ft., which had a mill value of $824,342,161. Toward these totals pine lumber furnished 57·1% of the footage and comprised 60·7% of the mill value. Further details confirming the pre-eminence of pine timber in the soft-wood lumber industry of the country are shown in the accompanying table

Production of Soft-wood (Coniferous) Lumber in the United States, 1925

Name of Wood	Production Board Feet	Av. Value at Mill per M bd. ft. $	Total Value $	% of U. S. Total Value
Pines	18,216,263,000	27·48	500,660,114	60·7
Yellow Pine	13,235,936,000	26·46	350,224,866	42·9
Western Yellow Pine	3,127,208,000	27·70	86,623,662	10·5
White Pine	1,521,128,000	32·58	49,558,830	6·0
Sugar Pine	306,992,000	44·79	13,750,162	1·6
Lodge-pole Pine	24,979,000	20·22	505,074	0·06
Other Conifers	13,495,635,000	23·98	323,682,047	39·3
Douglas Fir	8,154,373,000	20·94	171,752,571	20·8
Hemlock	2,139,631,000	21·58	46,173,236	5·6
Cypress	902,590,000	40·90	36,915,931	4·5
Redwood	510,639,000	33·99	20,420,454	2·5
Spruce	751,276,000	27·98	20,269,426	2·5
Cedar	372,162,000	38·80	14,439,886	1·8
White Fir	336,887,000	22·51	7,583,326	0·9
Larch (Tamarack)	306,991,000	18·25	5,602,586	0·7
Balsam Fir	19,686,000	26·65	521,631	0·06
Total Soft Woods (Conifers)	31,711,898,000	25·99	824,342,161	100·0

If the immense footage cut from the Douglas fir (*q.v.*), commonly known to a large part of the lumber trade as Oregon or western pine, is added to that produced from the true pines, then the total footage marketed as pine lumber amounted in 1925 to 26,356,657,000 bd. ft., with a mill value of $672,412,685, or 68·8% of the footage and 62 6% of the mill value of all lumber manufactured in the United States.

Commercially, the lumber cut from the various kinds of pine is known as *white, yellow, western yellow, sugar* and *lodge-pole* pine, and is classified under these descriptive names in the census of manufactures. White-pine lumber includes that produced from the eastern white or Weymouth pine, the western white pine, the grey or jack pine and the Norway or red pine, the two last named belonging botanically with the yellow pines. Prior to 1900 the eastern white pine was one of the chief lumber-producing trees in America, but the original forests have become so depleted that the tree now contributes only a minor fraction of the lumber marketed as white pine. The lumber from the eastern white, the grey and the red pine is mostly cut in the northern border States from Maine to Minnesota. Western white-pine lumber is practically all produced in Idaho (389,267,000 bd. ft.) and Washington (90,559,000 bd. ft.).

Yellow-pine lumber is cut mainly in the southern States; 70% of the total is produced in five States: Mississippi, Louisiana, Alabama, Texas and Georgia, which rank in the order named. The kinds of pine furnishing yellow-pine lumber all belong to the pitch pine group, and include the longleaf, loblolly, shortleaf, sand, slash, pitch, spruce, pond, mountain and Virginia pine, the longleaf, shortleaf, loblolly and slash pines ranking among the most important.

Western yellow-pine lumber, practically all cut from *P. ponderosa*, is produced chiefly in Oregon, 32%; California, 25%; Washington, 14%, and Idaho, 12%.

Sugar-pine lumber, cut from a single species (*P. Lambertiana*) and produced commercially only in California (97·5%) and Oregon (2·5%), in 1925 commanded the highest average price at the mill of any pine lumber cut in the United States. Lodge-pole pine lumber is produced in small quantities in the Rocky Mountain States—Wyoming contributing 48%; Colorado, 42%, Montana, 5%; and Utah, 4%, of the total footage. *See* UNITED STATES: *Fauna and Flora*, Plate VII., and the map showing forest distribution.

For further details *see* F. Engler and A. Prantl, *Die natürlichen Pflanzenfamilien* (1887–1908); A. Veitch, *Manual of the Coniferae* (1915); C. S. Sargent, *Manual of the Trees of North America* (1905, 2nd. ed. 1922); L. H. Bailey, *Manual of Cultivated Plants* (1924); G. B. Sudworth, "Check List of the Forest Trees of the United States," *U.S. Dept. Agric. Misc. Cir.* 92 (1927).

PINE-APPLE. The pine-apple so called consists in reality of the inflorescence of the plant, the originally separate flowers of which, together with the bracts supporting them, become fleshy and consolidated into one mass. The swelling and fusion of the tissues take place after the process of fertilization, and it may be that the richly perfumed succulent mass is an aid in the distribution of seed by affording food to certain animals. In the highly developed cultivated pines, however, it frequently happens that the seeds do not ripen properly. The pine-apple, *Ananas sativus*, is a member of the family Bromeliaceae, of tropical American origin, where it is widely spread; and it is now naturalized in the tropical regions of the Old World. It is cultivated on an extensive commercial scale in the Hawaiian Islands.

Evelyn in his *Diary* mentions tasting a pine-apple from Barbados at the table of Charles II., and this is we believe the first mention of the fruit in English literature. For many years pine-apples

PINE-APPLE (ANANAS SATIVUS), FROM A MODERN PHOTOGRAPH OF PINE-APPLES GROWING IN THE OPEN

were cultivated in large private gardens, but owing to the great developments in the West Indies, etc., they are no longer grown in Britain or Europe.

PINE-BEETLE, the name applied to several beetles (*see* COLEOPTERA) that attack pines and other coniferous trees, particularly in North America. The most important of these are *Dendroctonus ponderosa* which has done great damage to the timber of the Black Hills forest reserve; it attacks the main trunk of the tree. The wood engraver bark beetle (*Xyleborus coelatus*) attacks the white and yellow pines (*Pinus strobus* and *P. palustris*), while *X. pubescens* feeds on *P. inops*. All these beetles belong to the bark-boring family *Scolytidae*. (*See* COLEOPTERA; ENTOMOLOGY: *Economic*.)

PINE BLUFF, a city of Arkansas, U.S.A., 45 m. S.S.E. of Little Rock, on the south bank of the Arkansas river, at an altitude of 215 ft.; county seat of Jefferson county. It is served by the Missouri Pacific and the St. Louis Southwestern railways, and has a municipal airport of 224 ac., 1·5 m. north of the city. Pop. (1920) 19,280 (33% negroes); estimated locally at 30,000 in 1928. The city stands on bluffs overlooking the river. It is the seat of the State industrial school for boys, and of the Agri-

cultural, Mechanical and Normal school for negroes (opened 1875), a branch of the State university. Its wholesale and jobbing business covers most of southern Arkansas, and parts of Texas, Louisiana and Mississippi. Its manufactures in 1925 were valued at $10,142,154, and include railway shops, lumber-mills and woodworking plants, and factories making locomotive and car castings, brake shoes, automobile bodies and tops, mixed feeds, cotton yarn and knit underwear. The cotton exchange handles 150,000 bales in a normal year, of which 40,000–70,000 bales (of strong fibre, and averaging 1⅛ in. in length of staple) is grown in Jefferson county. There is an ample supply of natural gas and hydro-electric current. The city's assessed valuation for 1927 was $12,856,850. Bank deposits on June 30, 1928, aggregated $13,226,667. Pine Bluff was laid out in 1832 and chartered as a city in 1885.

PINEHURST, a winter resort in the long-leaf pine region of the Sand Hills of North Carolina, U.S.A.; 62 m. S.W. of Raleigh, on Federal highways 1 and 15 and the Norfolk Southern railroad, 650 ft. above sea-level. The resident population was about 1,500 in 1928 (33% negroes), and the number of visitors averages about 10,000 through the season (October to May). Pinehurst has 81 holes of golf, laid out by Donald Ross, 100 m. of bridle paths, and generous provision for polo, tennis, archery, trap and rifle range shooting, flying and horse-racing.

PINEL, PHILIPPE (1745–1826), French physician, was born at Saint-André, Tarn, France, on April 20, 1745. He took his doctor's degree at Toulouse in 1773. His first publication was a French translation of William Cullen's *Nosology* (1785); it was followed by an edition of the works of G. Baglivi (1788), and in 1791 he published a *Traité medico-philosophique sur l'aliénation mentale* in which he advocated a more humane treatment of the insane. It is on this advocacy and on the practical effect he was able to give to his ideas that his fame rests. His opportunity came with his appointment in 1792 as head physician of the Bicêtre, and two years afterwards of the Salpêtrière. His chemical lectures at the Salpêtrière formed the basis of his *Nosographie philosophique* (1798) which was further developed in *La Médicine clinique* (1802). Pinel was made a member of the Institute in 1803, and soon afterwards was appointed professor of pathology in the École de Médecine. He died at Paris on Oct. 26, 1826.

See notices by E. Pariset and Esquirol in *Mémoires de l'Académie de Medicine* (1828).

PINE-NUT or **PINON:** *see* NUT.

PINERO, SIR ARTHUR WING (1855–), English dramatist, was born in London on May 24, 1855, the son of John Daniel Pinero, a Jewish solicitor, whose family was of Portuguese origin, long established in London. A. W. Pinero was engaged in 1874 as an actor at the Theatre Royal, Edinburgh, and came to London in 1876, to play at the Globe theatre. Later in the year he joined the Lyceum company, of which he remained a member for five years. The first piece of his to see the footlights was *£200 a Year,* played in Oct. 1877, at the Globe theatre for the benefit of F. H. Macklin.

The first play to make a hit was *The Money Spinner* (Theatre Royal, Manchester, Nov. 1880); but in *The Squire* (St. James's Theatre, Dec. 1881) he attempted serious drama, and gave promise of the qualities of his later work. In 1883 and 1884 Pinero produced seven pieces, but the most important of his works at this period were the successful farces produced at the Court theatre: *The Magistrate* (March 1885), which ran for more than a year; *The Schoolmistress* (March 1886); *Dandy Dick* (Jan. 1887), revived in February 1900; *The Cabinet Minister* (April 1890), and *The Amazons* (March 1893). Two comedies of sentiment, *Sweet Lavender* (Terry's, March 1888) and *The Weaker Sex* (Theatre Royal, Manchester, Sept. 1888), met with success, and *Sweet Lavender* has enjoyed numerous revivals. With *The Profligate* (Garrick, April 1889) he returned to the serious drama.

The Second Mrs. Tanqueray (St. James's, May 27, 1893) dealt with the converse of the question propounded in *The Profligate,* but with more art and more courage. The piece aroused great discussion, and placed Pinero in the front rank of living English dramatists. It was translated into French, German and Italian, and the part of Paula Tanqueray, created in the first place by Mrs. Patrick Campbell, attracted many actresses, among others Eleonora Duse. His later plays include *The Notorious Mrs. Ebbsmith* (Garrick, March 13, 1895), *The Benefit of the Doubt* (Comedy, Oct. 1895), *The Princess and the Butterfly* (St. James's, April 7, 1897), *Trelawney of the Wells* (Court, Jan. 30, 1898), *The Gay Lord Quex* (Globe, April 8, 1899), *Iris* (Garrick, Sept. 21, 1901), *Letty* (Duke of York's, Oct. 8, 1903), *A Wife Without a Smile* (Wyndham's, Oct. 9, 1904), *His House in Order* (St. James's, Feb. 1, 1906), *The Thunderbolt* (St. James's, May 9, 1908), *Mid-Channel* (St. James's, Sept. 2, 1909), *The Big Drum* (1915), *The Freaks* (1918) and *The Enchanted Cottage* (1922). Pinero was knighted in 1909.

His *Plays* (11 vols. 1891–1895) have prefaces by M. C. Salaman. *See* also H. Hamilton Fyfe, *A. W. Pinero* (1902).

PINEROLO, city and episcopal see of Piedmont, Italy, in the province of Turin. Pop. (1921) 14,634 (town); 19,033 (commune). It is built on a hill-side just above the valleys of the Chisone and the Lemina, at a height of 1,234 ft. above the sea, 24 m. by rail S.W. of Turin. Till 1696 it possessed a citadel regarded as the key of Italy, in which Fouquet, De Caumont, Lauzun and the man with the iron mask were imprisoned, and city walls constructed by Thomas I. of Savoy.

PIN-EYED, a botanical term for flowers which occur in two forms, one of which shows the stigma at the mouth of the corolla, as in the primrose; the term is contrasted with thrum-eyed, where instead of a single stigma like one head of a pin there is a ring of five stamens visible.

PING-PONG: *see* TABLE TENNIS.

PINK, in botany, the common name for plants of the genus *Dianthus* of the family Caryophyllaceae. They are characterized by the presence of simple leaves borne in pairs at the thickened nodes, flowers terminating the axis and having a tubular calyx surrounded by a number of overlapping bracts, a showy corolla of five free long-stalked petals, ten stamens proceeding, together with the petals, from a short stalk supporting the ovary, which latter has two styles and ripens into a pod-like many-seeded capsule. The species are herbaceous perennials of low stature, often with very showy flowers. They are natives chiefly of southern Europe and the Mediterranean region, a few being found in temperate Asia and South Africa. Four species are wild in Great Britain. Of these, *D. armeria,* Deptford pink and *D. deltoides,* maiden pink, are generally distributed, *D. caesius,* Cheddar pink, occurs only on the limestone rocks at Cheddar, and *D. gallicus* only on the sand dunes of Jersey. Two others, *D. plumarius* and *D. Caryophyllus,* are more or less naturalized, and are interesting as being the originals of the pinks and of the carnations and picotees of English gardens. Garden pinks are derivatives from *D. plumarius,* a native of central Europe, with leaves rough at the edges, and with rose-coloured or purplish flowers. The use of "pink" for a colour is taken from the name of the plant.

The carnation (*q.v.*) and picotee are modifications of *Dianthus Caryophyllus,* the clove pink. This is a native of Europe, growing on rocks in the south, but in the north usually found on old walls. The carnation includes those flowers which are streaked or striped lengthwise—the picotees are those in which the petals have a narrow band of colour along the edge, the remainder of the petal being free from stripes or blotches. These by the old writers were called "gillyflowers." The sweet-william of gardens is a product from *Dianthus barbatus.*

The sea-pink, or thrift, *Armeria vulgaris,* is a member of the family Plumbagineae; it is a widely distributed plant found on rocky and stony sea-shores and on lofty mountains.

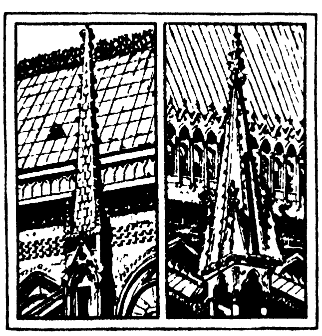
PINKERTON, ALLAN (1819–1884), American detective, was born in Glasgow, Scotland, Aug. 25, 1819. In 1842 he emigrated to Chicago, Ill., and in 1843 he removed to Dundee, Kane county, Ill. Here he ran down a gang of counterfeiters and was therefore appointed a deputy-sheriff of Kane county in 1846 and immediately afterwards of Cook county, with headquarters in Chicago. There he organized a force of detectives to capture thieves who were stealing railway property. This organization developed in 1852 into Pinkerton's National Detective Agency,

since well known for its activities in industrial disputes, etc. Some of his notable successes were the capture of the principals in the theft of $700,000 from Adams Express Company in 1866, and the uncovering of a plot to assassinate President-Elect Lincoln in February 1861, when he arrived in Baltimore on his way to Washington. In 1861 Pinkerton organized a system of obtaining military information in the Southern States, and from this system he developed the Federal secret service. One of his detectives, James McParlan, from 1873 to 1876 lived among the Molly Maguires (*q.v.*) in Pennsylvania and secured evidence which led to the breaking up of the organization. Pinkerton died in Chicago on July 1, 1884. He published *The Molly Maguires and the Detectives* (1877), *The Spy of the Rebellion* (1883), in which he gave his version of President-elect Lincoln's journey to Washington; and *Thirty Years a Detective* (1884).

PINKNEY, WILLIAM (1764–1822), American lawyer and statesman, was born in Annapolis, Md., on March 17, 1764. He was admitted to the bar in 1786, and from 1788 to 1792 practised in Harford county. In 1788 he was a member of the State convention which ratified the Federal Constitution for Maryland (1788–92), and in 1795 of the house of delegates (where in 1788 and 1789 he defended the right of slave-owners to free their slaves), and from 1792 to 1795 of the State executive council. From 1796 to 1804 he was commissioner to England to determine the claims of American merchants under the Jay Treaty of 1794 and adjusted a claim of $800,000 for Maryland on the Bank of England. In May 1806, with James Monroe, then minister at London, he was commissioned to treat with the British Government concerning the capture of neutral ships in time of war: from 1807 to 1811, after Monroe's return to America, he was resident minister in London. He was elected to the Maryland senate in Sept. 1811 and later was attorney-general of the United States, until 1814. In Aug. 1814 he was wounded at Bladensburg. He served in the National house of representatives Jan.–April 1816, and from 1816–18 was minister plenipotentiary to Russia and special minister to Naples, where he attempted to secure indemnity for the losses to American merchants by seizure and confiscation during the rule of Murat in 1809. He was a member of the committee which drew up the Missouri Compromise (*q.v.*). He was a member of the United States Senate from 1820 until his death, at Washington, on Feb. 25, 1822.

See William Pinkney, *The Life of William Pinkney* (1853) (1810–83); Henry Wheaton, *Some Account of the Life, Writings and Speeches of William Pinkney* (1828).

PINNACLE, in architecture, any vertical, decorative motive serving as the upper termination of a building or other form; hence, metaphorically, a summit or topmost limit. The word is distinguished from finial (*q.v.*) as signifying a larger motive, sometimes of considerable complexity, whereas a finial is a single ornament, and from tower or turret by the fact that a pinnacle is always a strictly subsidiary motive. Thus a Gothic tower and spire may be decorated with pinnacles, each one of which is capped by a finial. The chief architectural development of the pinnacle was in connection with buttresses (*q.v.*) of late Romanesque and Gothic buildings, as the addition of a pinnacle to a buttress not only added to the stability by increasing the weight, but also gave a decorative termination to the vertical line. Earlier pinnacles are simple square or rectangular structures capped with gable roofs or small spires, as in St. Remi at Reims (middle 12th century), and in the west front of Rochester cathedral (1130). With the development of the flying buttress (*q.v.*) pinnacles were increased greatly in size, and especially in France, in richness, and usually decorated with colonnettes on the outer corners and arches and crocketted gables above, sometimes with the addition of slender crocketted spires. Those of Notre Dame at Paris (end of 12th and beginning of 13th centuries) are typical. The most beautiful of the developed Gothic buttress pinnacles are those of the choir of Reims cathedral (*c.* 1240), in which the solid portion is preceded by an open shrine with a statue of an angel. In England, pinnacles were especially developed during the Decorated Period (*q.v.*) and play an important part in the tower designs in which they serve to soften the transition between a square tower and a spire above. Characteristic examples are those of Beverley minster (*c.* 1350) and the tower of St. Mary's at Oxford (*c.* 1300).



PINNACLE. LEFT: NOTRE DAME, PARIS; RIGHT: REIMS CATHEDRAL

The modern emphasis on vertical lines, resulting from steel construction, has led to a recrudescence of the use of pinnacles, and, especially in the tall buildings of America, they are common decorations of the sky line and of the various set-backs.

PINOCLE is a game of cards, similar to the French game of "bezique." It can be played by two, three or four persons.

Short Pinocle is played with two packs, from which all cards below the 9's are left out. The cards remaining are in order of value: 9, knave, queen, king, 10, ace (high). Twelve cards are dealt to each player, four at a time, and the next card is turned as a trump. It is placed under the pack, face up. If it is a 9, it is called the "dix" (pronounced "deece"), and the dealer scores 10 points for turning it. If any other card is turned, either player who has a 9 of trumps, after he has taken a trick, may take up the turned trump into his hand, and put his 9 face up, under the pack, and score 10 points for his 9. The holder of the other dix may lay it on the table, after he has taken a trick, and add 10 to his score.

The scoring is done by "melding," a word which comes from a German verb *melden,* to announce. After either player has taken a trick, he can lay the cards to be melded on the table, face up, and add the value of that meld to the score, but only one meld can be made after each trick taken. The values of the meld are as follows: the dix is 10; a marriage (any king and queen of same suit) 20; a royal marriage (a king and queen of trumps) 40; pinocle (the knave of diamonds and queen of spades) 40; 4 aces of different suits 100; 4 kings of different suits 80; 4 queens of different suits 60; 4 knaves of different suits 40; a royal straight (ace, 10, king, queen and knave of trumps) 150.

In melding, at least one new card must be laid out for each new meld. For instance, with spades for trumps, holding 150, the king and queen should be laid out first, and 40 trumps melded; then, after taking another trick, the ace, 10 and knave are laid down, and 150 melded. Then, if the player has the knave of diamonds, after taking another trick, it may be laid by the queen of spades, and pinocle melded. This order of melding, however, can only be followed when there are enough cards left in stock to be sure the player will have time, as no meld can be made after the last card is drawn from the stock. Otherwise 150 should be melded at once.

The cards left after the trump is turned are called "stock cards," and after each trick is taken in, and laid away, face down, each player draws a card, the winner drawing first. After they draw, no player can meld until he has taken another trick. Each player keeps in mind a count of the cards he has taken in play. They count as follows: aces 11, tens 10, kings 4, queens 3, and knaves 2 points; and he adds the total of those made to his melding score. The player who takes the last trick also adds 10. The total of the points in the two hands, including the last trick, is 250.

A player may follow suit, trump or discard, but after the last stock card has been drawn, each must follow suit or trump. If void both of the suit and trump, he may discard. One who violates this law loses the cards in the tricks he has won, in that hand. The game is 1,000 points, and when a player who has the lead believes that the value of cards in the tricks he has taken, added to the points he has already scored, equals 1,000, he may call "out" and stop the play. If he is short of the points, he loses the game.

Auction Pinocle has generally taken the place of short pinocle. Only in number of cards used, the values of the melds and the values of the cards and dixes are the games the same. Only three can play auction pinocle. If a fourth takes part, each dealer in turn takes no cards, and sits out during the play, but wins or loses the same as those who play against the successful bidder.

Fifteen cards are dealt to each player, usually three at a time, and at some time during the deal, three cards are dealt to the table, face down, and remain there. These are often called the "widow" or "dummy." Each player in turn, beginning with the eldest hand, may pass or may bid for the privilege of declaring the trump, and playing the hand. If all pass, the hands are thrown up, and there is a new deal. If bids are made, the first bid usually must be at least 200 or 250 (in some clubs at least 300), but may be whatever more the bidder thinks he can make. Each following bid must be at least 10 more, and the bidding continues until two players have passed. A player who has passed cannot bid again on that hand. When two pass, the bidding stops, and the contract goes to the last bidder, who becomes the contractor. The contractor now turns the three cards in the "widow" face up on the table, and adds them to his hand. He declares a trump, and lays his melds on the table, face up. In addition to the melds given above, the contractor may meld a "round trip" 240, if he holds a king and a queen in each suit, but if he makes this meld, a royal straight counts only 110. If these values, added, make his bid, he has won his contract, and the other players pay; but if, after counting his melds and dixes, he is short of the points bid, and his opponents refuse to concede the contract, he may play the hand and try to make up the shortage from the count of the cards in the tricks he takes. If he feels he cannot make his bid, he does not play, but pays

If the contractor decides to play, he takes all the cards up from the table, lays three not melded, face down from his own hand, which count as a trick for him. If he fails to lay these cards out, he loses. If he lays a trump he must announce it He now leads, and the other two are partners against him In the play of the hand, every player must follow suit or trump If void both of the suit led and trumps, a player may discard any card on the trick If trumps are led, each player that follows must play a higher card and win the trick if he can If void of trumps, he may discard The last trick counts ten for the one who wins it. If the number of points made by the value of the cards in the tricks the contractor wins, added to the points in his meld, make the number that he has bid, he collects for the number of points bid, from the players, no matter how many points he has made If the bid is 300, and he makes 500 points, he can only collect for 300. If the contractor plays the hand and fails to make his contract, he must pay double.

Each deal is a complete game, and is usually paid for at once by the losers For convenience, instead of keeping a score, each player usually takes 25 poker chips At the end of the hand, each player pays 2 chips for any loss under 300, 3 chips for a loss between 300 and 340, 5 chips for a loss from 350 to 390, 10 chips for a loss from 400 to 440, 15 chips from a loss from 450 to 490, 20 chips for a loss of 500. These figures are purely arbitrary. Players give any value they wish to each chip At the end of the sitting, each player owes for the 25 chips he had at the beginning, and collects for all the chips he has won, or pays for all the chips he has lost. (C. L. P)

PINSK, a town of Poland, in the province of Polesie, at the confluence of the Strumen and Pina rivers, 196 m S W by rail of Minsk. The river Pina connects it with the fertile regions in the basin of the Dnieper, and, by means of the Dnieper-and-Bug canal, with Poland and Prussia, while the Oginski canal connects it with the basin of the Niemen. Pottery, leather, oil, soap and beer are the chief products of the local industries The draining of the marshes around Pinsk was begun by the Russian government in 1872, and by 1897 8,000,000 acres had been drained at an average cost of 3s. per acre. Pinsk (Pinesk) is first mentioned in 1097 as a town belonging to Sviatopolk, prince of Kiev In 1132 it formed part of the Minsk principality. After the Mongol invasion of 1239–42 it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania; and in 1569, after the union of Lithuania with Poland, it was chief town of the province of Brest. Pinsk was annexed to Russia in 1795, and restored to Poland in 1918.

PINT, a liquid measure of capacity, equivalent to ⅛ of a gallon (derived probably through Spanish, from Lat *pincta*, *picta*, a painted or marked vessel). The imperial British pint = ·57 of a litre, 34·66 cu. in. The United States standard pint = ·47 of a litre, 28⅞ cu. in.

PINTO, FERNÃO MENDES (1509–1583), Portuguese adventurer, was born at Montemôr-o-Velho, of poor parents, and entered the service of a noble lady in Lisbon. He embarked for India in 1537 in a fleet commanded by the son of Vasco da Gama, and for 21 years travelled, fought and traded in China, Tartary, Pegu and the neighbouring countries, sailing in every sea, and introducing the musket into Japan. Though he was 13 times a captive and 17 times sold into slavery, his gay and dauntless spirit brought him through every misfortune He was soldier and sailor, merchant and doctor, missionary and ambassador; moreover, as the friend and travelling companion of St Francis Xavier, he lent the apostle of the Indies the money with which to build the first Jesuit establishment in Japan.

In Jan. 1554 Pinto was in Goa, waiting for a ship to take him to Portugal, when he decided to devote a large part of his capital to the evangelization of Japan. The viceroy appointed him ambassador to the king of Bungo in order to give the mission an official standing, and on April 18th he set sail with the provincial, Father Belchior Nunes. The missioners did not reach Japan until July 1556 On Nov. 14, 1556, Father Belchior and Mendes Pinto began their return voyage and reached Goa on Feb. 17, 1557. During his stay of a twelve-month there, Pinto left the company, being dispensed from his vows for want of vocation at his own request, though a modern authority states that he was expelled because he was a *marrano, i e*, had Jewish blood. He finally returned to Portugal on Sept 22, 1558, and settled at Pragal near Almada, where he married and wrote his famous book, the *Peregrination;* the ms , in fulfilment of his wishes, was presented by his daughter to the Casa Pia for penitent women in Lisbon, and it was published by the administrators in 1614. Philip II. of Spain gave him (1583) a pension for his services in the Indies. But the reward came too late, for he died on July 8

Pinto was on the whole a careful observer and truthful narrator, but he invented on occasion, and often repeats stories at second hand. Some witty Portuguese parodied his name into *Fernão, mentes? Minto!* ("Ferdinand, do you lie? I do!"), and the English dramatist Congreve only expressed the general opinion of the unlearned when he wrote in *Love for Love*, "Mendes Pinto was but a type of thee, thou liar of the first magnitude" In the narrative portions of his work Pinto's style is simple, clear and natural He did for the prose of Portugal what Camoens did for its poetry

The *Peregrination* has gone through many editions subsequent to that of 1614, and in 1865 Castilho published excerpts in his *Livraria classica portugueza* with an interesting notice of Mendes Pinto's life and writings. Versions exist in German (3 editions), French (3 editions), Spanish (4 editions), and in English by Henry Cogan, London (1663, 1692 and—abridged and illustrated, with introduction by Arminius Vambéry—1891). Cogan omits the chapters relating to Mendes Pinto's intercourse with, and the last days of, St Francis Xavier, presumably as a concession to anti-Catholic prejudice

See Christovão Ayres, *Fernão Mendes Pinto* (Lisbon, 1904) *Fernão Mendes Pinto e o Japão* (Lisbon, 1906); also *Subsidios . . . para a biographia de Fernão Mendes Pinto* by Jordão de Freitas (Coimbra, 1905).

PINTO. The brown, black and blue spots of discoloration of the whole body endemic in Mexico, Panama, Colombia and Venezuela, and known under the name were first held by Gastambide (*Presse med Belge*, 1881, Nos 33–41) as due to a vegetable parasite, whose spores and mycelial filaments may be detected among the deeper rows of cells of the rete mucosum The disease appears to be one of poverty, but it is contagious, and is sometimes seen in the well-to-do In villages of Tabasco (Mexico) it is said that 9% of the people thus suffer

PINTURICCHIO (1454–1513), Italian painter of the Umbrian School, whose full name was BERNARDINO DI BETTO (BENEDETTO) DI BIAGIO, the son of a citizen of Perugia, Benedetto or Betto di Biagio. He was probably a pupil of Fiorenzo di Lorenzo; and the two masters appear to have co-operated in the execution of the "Adoration of the Magi" from S Maria Nuova, now in the Pinacoteca of Perugia. After assisting Perugino in

the execution of his frescoes in the Sistine Chapel, Pinturicchio was employed by Niccolo Buffalini, advocate to the papal consistory, to decorate a little Gothic chapel in Ara Coeli on the Capitol with frescoes illustrating the life of San Bernardino of Siena. These frescoes were probably executed about 1484. They show the master at his best. The colouring is exceedingly harmonious, the landscape backgrounds full of atmosphere. Pinturicchio was employed by the Della Rovere family to decorate a series of chapels in the church of S. Maria del Popolo. The "Adoration of the Shepherds," in the chapel built by Cardinal Domenico della Rovere, was probably done about 1500. In the lunettes under the vault Pinturicchio's assistants painted small scenes from the life of St. Jerome.

The last paintings completed by Pinturicchio in this church were the frescoes on the vault over the retro-choir, a very rich and well-designed piece of decorative work, with main lines arranged to suit their surroundings in a very skilful way. No finer decoration of a quadripartite vault exists.

In 1492 Pinturicchio was summoned to Orvieto, where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome, and was employed by Pope Alexander VI. (Borgia) to decorate a suite of six rooms in the Vatican, which Alexander had just built. Of these rooms, called after their founder the *Appartamenti Borgia,* five still retain his frescoes. The upper parts of the walls and vaults are not only covered with painting, but further enriched with delicate stucco work in relief. Pinturicchio employed many assistants. The second room, however, with scenes from the lives of saints, was painted by the master himself, and contains one of his famous works, "The Dispute of St. Catherine."

On the vault of the sacristy of S. Cecilia in Trastevere, Pinturicchio painted the Almighty surrounded by the Evangelists. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now, like the rest of his work at Orvieto, almost destroyed.

Among his panel pictures the following are the most important. An altarpiece for S. Maria de' Fossi at Perugia, painted in 1496–1498, now moved to the picture gallery, is a Madonna enthroned among saints, graceful and sweet in expression. Another fine altarpiece, similar in delicacy of detail, and probably painted about the same time, is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin, with the apostles and other saints below. Several well-executed portraits occur among the kneeling saints. Other panel paintings by Pinturicchio exist in the cathedral of Spello, in the Siena gallery, at Perugia, and in the collection of the Earl of Crawford at Haigh Hall.

In 1501 Pinturicchio painted several fine frescoes in S. Maria Maggiore at Spello—all very decorative and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardinvs Pintvrichivs Pervsinvs." The most striking of all Pinturicchio's frescoes, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1492 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Aeneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract specially provided that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. The series were finished in 1507. Outside the library, over the door, we have the coronation of Pius III. in which he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael. In 1513, the year of his death, he painted a highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. He died at Siena, on Dec. 11, 1513, and is ranked as one of the greater Umbrian painters. His worth has been undervalued, partly owing to the dislike which tinges Vasari's biography of him. Even Crowe and Cavalcaselle hardly did him justice. G. Morelli has however disproved the myth that Raphael, then a youth of 20, supplied cartoons or drawings for the aged master in his work in the Libreria del Duomo, Siena. These drawings (Venice) are not by Raphael but by Pinturicchio.

See G. Morelli, *Italian Masters in German Galleries* (1883); Vermiglioli, *Mémoire di Pinturicchio* (Perugia, 1837); and the valuable notes and appendix of Milanesi's edition of Vasari, iii. 493–531 (Florence, 1878); E. Steinmann, *Pinturicchio* (Leipzig, 1898); E. M. Phillipps, *Pinturicchio* (1901); W. Bombe, *Geschichte der Peruginer Malerei* (1912).

PINWELL, GEORGE JOHN (1842–1875), British water-colour painter, was born at Wycombe, and educated at Heatherley's Academy. Like Frederick Walker and A. B. Houghton, he belonged to a group whose style was derived from drawing upon wood for book illustration. As he died young his works are few, but their promise was great. His earliest drawings appeared in *Lilliput Levée.* He did a little work for *Fun* and executed several designs for the silversmiths, Elkingtons. In 1863 his first drawing appeared in *Once a Week,* and from that time his work was in constant demand in current periodicals. His most important productions, made for the Dalziel brothers, were illustrations of Goldsmith, of Jean Ingelow's poems, Robert Buchanan's *Ballads of the Affections,* and the *Arabian Nights.* Of Pinwell's pictures in colour, which are distinguished by a remarkable, jewel-like quality and marked by his strong love of pure, bright colour and opalescent effect, the chief are the two scenes from the *Pied Piper of Hamelin, Gilbert à Becket's Troth, Out of Tune* or *The Old Cross, A Seat in St. James's Park,* and *The Elixir of Life.*

In 1874 Pinwell fell seriously ill and went to Africa for the winter. He painted several remarkable pictures at Tangier, but he returned to die on Sept. 8, 1875.

See G. C. Williamson, *Life of George J. Pinwell* (1900).

(G. C. W.; X.)

PINZON, a family of Spanish navigators, of Palos in Andalusia, three members of which—Martin Alonzo, Francisco and Vicente Yañez, brothers—were associated with Columbus in the discovery of America.

MARTIN ALONZO PINZON, born about the middle of the 15th century, in the expedition of 1492, commanded the "Pinta," on which his brother Francisco was pilot. On Oct. 6, he suggested to Columbus (when already in the longitude of the Bermudas) to change the course of the expedition from due west to south-west; on Oct. 7 this suggestion was adopted, bringing the fleet to the landfall at Guanahani (San Salvador, Watling Island) in the Bahamas (Oct. 12, 1492). On Nov. 21, near the east end of the north coast of Cuba, he left Columbus, making eastward in search of the supposed gold-land. On Jan. 6, 1493, he rejoined the admiral, but on the return journey again left him and landed at Bayona in Galicia. He died soon afterwards.

VICENTE YAÑEZ PINZON commanded the "Nina" in 1492–1493 and remained loyal to Columbus throughout. In after years he made important discoveries on his own account. In December 1499 he sailed with four caravels across the Atlantic to the south-west, and on Feb. 7, 1500, he landed at Cape S. Agostinho, near its most easterly projection (called by him Cape Santa Maria de la Consolacion). Proceeding southwards a short distance, he then turned north, followed the coast to the north-west, discovered the Amazon estuary, and went as far as what is now Costa Rica. After touching at Haiti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in September 1500. Although he was created governor of the newly discovered lands by Ferdinand and Isabella, he did not take possession. In 1507 he sailed with Juan Diaz de Solis along the east coast of Central America. In 1509, again with De Solis, he coasted the Atlantic side of South America as far as the La Plata estuary, hoping to find an opening westwards leading to the Spice Islands. According to Herrera, he reached 40° S., not recognizing the La Plata and turning back about the mouth of the Rio Negro, but this is probably an exaggeration. After 1523 all traces of Vicente are lost.

PIOMBINO, a seaport of Tuscany, Italy, in the province of Pisa, 8 m. by rail W.S.W. of Campiglia Marittima (which is 53 m. S.S.E. of Pisa), 62 ft. above sea-level, at the southern extremity of the peninsula of the Monte Massoncello. Pop. (1921) 20,692 (town); 23,622 (commune). It is the port of embarkation for Elba, the nearest point of which is about 6 m. to the south-west, and originally belonged to Pisa. It gives the title of prince to the Buoncompagni Ludovisi family, who, however, no longer own it. Large iron-smelting and tin plate works are situated here. In 1926 5,995 ships, of 945,218 tons, entered and cleared the port, while at Portoferraio, in Elba, 6,184 ships, of 1,214,432 tons, entered and cleared.

PIOTRKÓW, a town of Poland, in the province of Lodz, and formerly the seat of the high court of Poland, on the railway from Warsaw to Vienna, 90 m. south-west of the former and 5 m. west of the river Pilica. Pop. (1921), 41,000. It is a well-kept town, with numerous gardens, and has flour-mills, saw-mills, tanneries, agricultural machinery works, and breweries. One of the oldest towns in Poland, Piotrków was in the 15th and 16th centuries the place of meeting of the diets, and here the kings were elected.

PIOZZI, HESTER LYNCH (1741–1821), English writer, well known as the friend (Mrs. Thrale) of Samuel Johnson, was born on Jan. 16, 1741, her father being John Salusbury of Bobbel, Carnarvonshire. In 1763 she married Henry Thrale, a rich Southwark brewer, whose house was at Streatham on the south-east corner of Tooting Bec Common. There was very little sympathy between the lively girl and Thrale, who was 13 years her senior, but gradually she drew round her a distinguished circle of friends.

She was introduced to Samuel Johnson in 1765 by Arthur Murphy, who was an old friend of her husband's. In 1766 Johnson paid a long visit to Streatham, and from that time was more or less domesticated with the Thrales. (*See* JOHNSON, SAMUEL.) Fanny Burney was another of her friends. She was very sensitive, and sometimes thought that Mrs. Thrale gave herself airs of patronage. Meanwhile, in 1772, Thrale was threatened with bankruptcy. The situation was saved by his wife's efforts, and in the next year Thrale travelled, leaving her in charge of his affairs. He was twice returned for the borough of Southwark, chiefly through her efforts. In 1781 Thrale died, and Dr. Johnson helped the widow with her business arrangements, advising her to keep on the brewery, until she "cured his honest heart of its incipient passion for trade, by letting him into some, and only some, of its mysteries." The brewery was finally sold for £135,000.

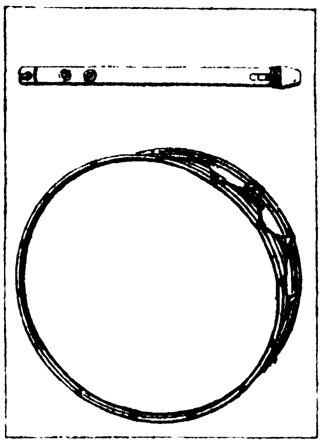
Mrs. Thrale had met Gabriele Piozzi, an Italian musician, in 1780. In 1784 they were married. Johnson told Miss Burney that he drove the memory of Mrs. Thrale from his mind, burning every letter of hers on which he could lay his hand. The Piozzis presently left England to travel in Italy. At Florence they fell in with Robert Merry and the other "Della Cruscan" writers ridiculed by William Gifford in his *Maeviad* and *Baviad*, and she contributed some verses to their *Florence Miscellany* in 1785. In 1786 she published *Anecdotes of the late Samuel Johnson, during the last twenty years of his life*, which was severely criticized by Boswell. She was ridiculed by "Peter Pindar" in *Bozzy and Piozzi; or the British Biographers, A Town Eclogue* (1786). But though Miss Burney and some others held aloof, the Piozzis found plenty of friends when they returned to London in 1787. Piozzi died at Brynbella, a villa he had built on his wife's Carnarvonshire estate in 1809, and Mrs. Piozzi gave up her Welsh property to her husband's son, and spent most of the rest of her life at Bath and Clifton. She retained her vivacity to the last, celebrating her 80th birthday by a ball to six or seven hundred people at Bath. She died at Clifton on May 2, 1821.

From 1776 to 1809 she kept a note-book which she called "Thraliana." Her well-known poem of the "Three Warnings" is to be found in many popular collections. *Letters to and from the late Samuel Johnson* appeared in 1788; *Observations and Reflections made in the course of a Journey through France, Italy and Germany*, in 1789; and in 1801 she published *Retrospection; or a review of the most striking and important events, characters, and situations . . . which the last eighteen hundred years have presented to the view of mankind* (1801).

See *Letters and Literary Remains of Mrs. Piozzi (Thrale)*, edited with notes and an *Introductory Account of her Life and Writings* by *A. Hayward* (1861); *Piozziana; or Recollections of the late Mrs. Piozzi by a Friend* (1833), the anonymous friend being Edward Mangin (1772–1852); L. B. Seeley, *Mrs. Thrale, afterwards Mrs. Piozzi* . . . (1891), and G. Birkbeck Hill, *Johnsonian Miscellanies* (1897); also Percival Merritt, *The True Story of the So-called Love Letters of Mrs. Piozzi* (1928), which exposes the misrepresentation of the "love letters" to William Conway the actor written when she was an old lady and published in 1843. The copies of these letters are shown to be grossly misleading. Also works noted in bibliography to JOHNSON, SAMUEL.

PIPE, a hollow stem of clay, wood or other material with a bowl at one end used for smoking tobacco, opium or other narcotic, or any medicinal substance. *See* PIPE, SMOKING and TOBACCO PIPE.

PIPE and TABOR, a popular mediaeval combination of a small pipe or flageolet and a small drum. The tabor being fastened to the performer's left elbow, the hands remained free, the right beating the little drum with a stick to mark the rhythm, while the left held and fingered the pipe with thumb and first two fingers. The pipe and tabor are said to be of Provençal origin.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE PIPE AND TABOR, STILL IN USE IN CERTAIN PARTS OF FRANCE

PIPE CLAY. A natural clay, one of the names given to impure kaolin or china clay. It occurs in beds where kaolin has been washed away from its original site and deposited in a hollow. It is used to make primitive tobacco pipes and for whitening military belts, etc.

PIPE-FISH, the name given to fishes which, with the sea-horses, form the family *Syngnathidae* of the order *Solenichthyes*. The pipe-fishes are long and slender, with the body encased in bony rings, and a small, toothless mouth at the end of a long, tube-like snout; the gill-filaments are reduced in number and appear as rounded lobes or tufts. About 100 species are known from warm seas, and a few from rivers. Pipe-fishes frequent sea-weeds, and swim slowly by rapid undulations of the small dorsal fin.

PIPE-LINE: *see* PETROLEUM.

PIPER, CARL, COUNT (1647–1716), Swedish statesman, was born at Stockholm on July 29, 1647. In 1689 he was made one of the secretaries of state, and Charles XI. recommended him on his deathbed to his son and successor, Charles XII. Piper became the most confidential of the new sovereign's ministers. In 1697 he was made a senator and set over domestic affairs while still retaining his state-secretaryship. In 1698 he was created a count, in 1702 appointed chancellor of Uppsala University, and during the first half of the Great Northern War, as the chief of Charles's perambulating chancellery, he was practically prime minister. But he belonged to the school of Bengt Oxenstjerna (*q.v.*) and was therefore an avowed advocate of a pacific policy. He protested in vain against nearly all the military ventures of Charles XII., *e.g.*, the War of Deposition against Augustus of Saxony and Poland, the invasion of Saxony, the raid into the Ukraine. Again and again he insisted that the pacific overtures of Peter the Great should at least be fairly considered, but his master was always immovable. Piper was taken prisoner at Poltava (1709), and died at Schlüsselburg on May 29, 1716.

See W. L. Svedelius, *Count Carl Piper* (Stockholm, 1869).

(R. N. B.)

PIPERACEAE, in botany, the pepper family, comprising seven genera with 1,150 species, tropical herbs and shrubs. The leaves have a pungent flavour and the flowers lack both calyx and corolla. *Piper* includes the pepper (*q.v.*)

PIPERAZINE, a colourless crystalline solid melting at 104° C and boiling at 145° C, soluble in water and used medicinally as a uric acid eliminant. Piperazine, $C_4H_{10}N_2$, was first obtained by A. v. Hofmann by the action of ammonia on ethylene dichloride or dibromide. It is manufactured from the latter dihalide and aniline, the intermediate product, diphenylpiperazine, being converted successively into its dinitroso-compound and piperazine.

PIPERINE, an alkaloid (*see* ALKALOIDS) found in the fruits of certain peppers. It forms white prisms, melts at 128°–129° C, is almost insoluble in water, but readily so in alcohol or ether, and is a very weak base, salts being only formed with mineral acids, and these are dissociated by water. Alcoholic potash decomposes piperine, $C_{17}H_{19}O_3N$, into piperidine, $C_5H_{11}N$, and piperic acid, $C_{12}H_{10}O_4$, indicating that the alkaloid is a piperidide of piperonylic acid. It was synthesized (Rugheimer, 1882) by the action of piperonyl chloride on piperidine.

PIPERITONE is the sole ketonic constituent of eucalyptus oils, from which it may be either fractionally distilled or extracted with sodium bisulphite. It occurs in the "peppermint group" of eucalyptus leaf-oils, in association with *l*-α-phellandrene, and has been found altogether in 23 species; these grow mainly in south-eastern Australia and Tasmania, and are characterized by a butterfly-wing leaf-venation. A maximum content of about 45% of piperitone is reached in the oil of the Broad-leaved Peppermint (*E. dives*). Piperitone, $C_{10}H_{16}O$, Δ^1-menthen-3-one, is a colourless liquid (b.p. 232°), with an odour of peppermint. The eucalyptus ketone is laevo-rotatory, with $[\alpha]\hat{D}$–53·9°; but *d*-piperitone, having $[\alpha]\hat{D}$–62·5°, has been isolated from the essential oil of a Himalayan grass, *Andropogon Jwarancusa*. The optically active ketone racemizes easily, owing to enolization. When hydrogenated according to Paal's method, *l*-piperitone yields mainly *d-iso*-menthone, and by reduction in other ways it has been used commercially as a source of *dl*-menthol. It may be oxidized to thymol.

PIPERNO (anc. *Privernum*), a town of the province of Rome, Italy, 54 m. S.E. of Rome by rail. Pop. (1921), 7,414. The mediaeval town was founded in the 10th century on a hill 490 ft. above sea-level, by refugees from the Roman town of Privernum, lower down (118 ft. above sea-level) on the high-road, 1¼ m. to the north, at the mouth of a low pass leading through the Volscian mountains to the valley of the Sacco. Here are scanty remains of the Roman period, though the ruins are largely mediaeval. The ancient Volscian town probably stood on the site occupied by the mediaeval and modern town. Privernum was finally captured in 329 B.C., and in 318 the tribus Oufentina was founded (*see* LATIUM). The mediaeval town has a picturesque piazza, with a Gothic cathedral (1283), and a Gothic town-hall; and Gothic churches. Polygonal terrace walls of the Roman or pre-Roman period exist at various places in the vicinity.

See H. H. Armstrong in *American Journal of Archaeology* (1911), 44 *sqq.*, 170 *sqq.*, 386 *sqq.*

PIPE ROLLS or the Great Rolls of the Exchequer are a long series of financial records of the English crown. The first extant Pipe Roll is that for the 31st year of the reign of Henry I. The continuous series begins with the second year of Henry II.'s reign and the annual succession of rolls is almost unbroken till 1834, when the last relics of the ancient financial system of the English mediaeval kings were swept away. The most plausible explanation of the name Pipe Rolls is that when rolled up and stacked in their presses the rolls looked like pipes. Up to the beginning of the 13th century the Pipe Rolls are the only consecutive series of official records which have survived; it was not until the reign of John that the Chancery records were systematically preserved. Therefore, the value of the Pipe Rolls for the last half of the 12th century can hardly be overestimated. By them the narratives of the chroniclers can be checked, and from them most of our knowledge of the actual working of the legal system in Henry II.'s reign comes. They are a mine of information about the personnel of the government and the gradual development of the new administrative offices. They are the best authority for the descents of the great families of feudal England. For the historian of English towns they provide a vast mass of material. Calculations as to the amount of the royal revenue have been made from them, but such calculations can only be approximate, since much money was paid directly into the king's privy purse and recorded in no roll that survives.

Consisting of a varying number of skins of parchment about 14 inches wide and a yard long sewn together at the top, the rolls are not easy to consult. Their matter too is not easy reading, nor their method of book-keeping easy to understand. The accounts are entered county by county, the sheriff being responsible for the account of his shire. Other accounts, known as foreign accounts, appear sometimes on the rolls, accounts of royal manors by their custodians, accounts of escheats, or of towns. The clerks enter debts long after all hope that they may be paid has passed away. In 1883 the Pipe Roll Society was formed to publish the rolls up to 1200. It hopes to carry the work up to the end of John's reign. In later centuries, the Pipe Rolls lose much of their importance, but interesting matter can be found in the foreign accounts which continue to appear on the rolls. When the escheat rolls begin one great source of foreign accounts is lost to the Pipe Rolls. In this way by a process of splitting off, and the setting up of new accounting offices the ancient sheriff's account recorded in the Pipe Rolls becomes insignificant and stereotyped. The continuation of the series to 1834 is a remarkable illustration of English administrative conservatism. (D. M. S.)

PIPERONAL, an aromatic aldehyde with an agreeable smell, resembling that of heliotrope. It forms long colourless crystals, which melt at 37° C and boil at 263° C and is much used in perfumery. It is only slightly soluble in cold water, but readily soluble in alcohol and in ether. It is also called heliotropine, and is protocatechuic aldehyde methylene ether, $CH_2O_2{\cdot}C_6H_3{\cdot}CHO$. It is prepared by oxidizing piperic acid with potassium permanganate (R. Fittig, 1869), by condensing methylene iodide with protocatechuic aldehyde (R. Wegscheider, 1893), or by oxidizing isosafrole with chromic acid. When heated with dilute hydrochloric acid to 200° C it yields protocatechuic aldehyde, $C_7H_6O_3$, and carbon. It readily combines with sodium bisulphite and with various bases (ammonia, aniline, methylamine, etc.).

PIPE SMOKING. The original source of the idea of smoking must be sought in the sense of smell. This was much keener in primitive man than in man of the more advanced stages. With the pleasure derived from aroma, there was probably a sense of mystery at the sight of the smoke rising up into the air. Thus there was an element of religious ceremony in the burning of pleasant-smelling substances among primitive folk, in whatever part of the world we may be able to study their ways.

The ritual element is enhanced by another circumstance. Herodotus, in the fifth century B.C., describes a practice of the Scythians, a Mongol people settled in south-eastern Europe, between the Carpathian mountains and the River Don. Throwing the leaves of a certain plant (which was probably hemp) upon a fire, they sit round and, inhaling the smoke, "they grow drunk with the fumes as the Greeks do with wine," until they jump up and begin to dance and sing. Herodotus seemed to regard this simply as an orgy; but inhalation was certainly used to produce a super-normal condition of mind in many parts of the world. When Columbus discovered America, he found the habit established of inhaling tobacco, to induce a state of trance, during which visions were seen, which were accepted as divine revelations. The intoxicating vapour at Delphi which inspired the Pythian priestess may have been artificially produced, since no natural source has been found.

The invention of an implement to concentrate the smoke was an advance. Such an implement is the Y-shaped tube described by G. Fernandez de Oviedo in his *History of the Indies* (1535). The two horns of the "Y" were inserted in the nostrils, and smoke from tobacco burning in a censer was drawn up through the tube. This was the ceremonial method of smoking prevalent in the Antilles when Columbus and his followers reached them, side by side with a common use of the tobacco-leaf rolled up and smoked like a cigar. Bernal Diaz, who accompanied Cortez to Mexico, describes the inhalation of tobacco through a tube. But we have much earlier evidence from Mexico. At the ruined city of Palenque, in the southern province of Chiapas, there are the

remains of a "Temple of the Cross," which seems to belong to the beginning of the second century A.D. Here, on one of two stone slabs on either side of a doorway, is represented a figure of a priest, clad in a jaguar-skin cloak and a head-dress representing a mythical bird, who is blowing out a smoke-offering through a straight tube. This Palenque sculpture is the work of the Mayas, the mysterious race which preceded the Toltecs and the Aztecs in Mexico. Other Maya sculptures portray the straight smoking-tube, both as an emblem in one of the hands of Chac, the god alike of rain-and-thunder and of fertility, and as an apparently ordinary implement for smoking. Lionel Wafer, at the end of the 17th century, speaks of a roll of tobacco, 2ft. or 3ft. long and as thick as a man's wrist, being lighted by a boy, and the smoke being puffed into the faces of a company who made funnels of their hands and inhaled it.

Whatever the original use of the straight tube (which is found in a variety of materials—bone, wood, cane, stone of kinds not too hard to work, and pottery), the use of it as a pipe for tobacco ages before America was discovered by the early European adventurers is well established. The first modification of the type is that found in the burial-mounds of the Muskogee Indians, in the south-eastern portion of what is now the United States The tube is bent up at one end, with a widening of the "bowl" formed by this end. Pipes on these lines were obviously the model for the clay pipe as known to Europe, which is only natural, since the first Europeans to introduce the use of the tobacco-pipe into their own countries learned the habit of smoking not from the West Indies, but from the Indians of the eastern mainland.

The next modification of the tube, which is found in Ohio and Virginia in the burial-mounds of another Indian tribe, the Algonquins, converts it from a one-piece to a two-piece pipe. Whatever the material used, usually some kind of stone, the stem was liable to be broken, necessitating a makeshift stem, if the bowl was to continue in use From this the transition is easy to a bowl alone, into which a wooden stem could be inserted.

While the tobacco-pipe was thus evolving in North America apparently a two-piece pipe arose independently in South America. In the upper part of the southern continent true pipes were not used, though the Y-shaped tube, of which we have already heard, was employed for inhaling snuff. Otherwise cigar-smoking was the ordinary form of indulgence in tobacco But in South Brazil in 1650 the traveller Jan Nieuhoff found a great Indian tribe smoking pipes with bowls made of nut-shells and with stems of reed or hollowed wood. This kind of pipe, with a small bowl, was the prototype of the pipes of Turkey, Persia and the Far East, since the Portuguese took it with them from Brazil along their trade-route in the Old World Much larger pipes were also used by the same Brazilian tribe, with bowls of stone, clay, or wood, and are found to-day among their descendants, now living on the Upper Amazon.

The two-piece pipe is also found in the steppes of Central and Western Asia, and the Kalahiri region of South Africa Both these are woodless countries, scantily inhabited by people mostly nomadic. Here "earth-smoking" is found The most primitive method is to dig a small pit in the ground, to serve as a bowl; to insert a stick through the earth to the bottom of this pit; and then to withdraw the stick, leaving a hollow tube The smoker has to lie flat on the ground and apply his mouth to the end of the tube An improvement on this uncomfortable method is the fashioning of a rough bowl of clay above the surface of the ground, with a tube formed as before with the aid of a stick. Such an earth-pipe, when dry, can be detached and carried about. The insertion of a separate mouthpiece into the end of the hollow tube would convert it into a two-piece pipe. In quite a different part of the world, among some of the North American Indians, a hollow reed stuck into a bowl made of wet clay is said to serve as an emergency pipe.

The credit of the first invention of the pipe cannot be assigned to any one people nor is it certain that smoke proceeded always from tobacco-leaf. There is hemp, which, in many parts of the world at least, long preceded tobacco. There are many herbs, such as henbane, which were commonly used in Europe, for how many centuries we do not know. Opium-smoking, on the other hand is a late development. Early evidence concerning the tobacco-pipe comes from America only, for the reason that the tobacco-plant is a native of America. The theory that both the plant and the habit of smoking derived originally from Africa and reached the western coast of America by way of the Indian and Pacific Oceans, rests on an insufficient basis Smoking, no doubt, is a custom of great antiquity in Africa; but it is the smoking of hemp, as exemplified notably among the Bushmen of the Kalahiri Desert The evolution in Africa of the pipe for hemp-smoking has, so far as we can tell, been from the earth-pit, through the simple tube, to the *Dakka* (hemp) pipe, which is the ancestor of the water-pipes of various kinds used for tobacco in the East Among the Bushmen an animal's horn, generally an antelope's, is used as the water-vessel Among other African tribes ox-horns, gourds, bamboos and wooden stems are to be seen. It was thus the African hemp-smokers who gave to the smokers of tobacco this idea of using a pipe in which fumes should be filtered and cooled by passing through water.

See A. Dunhill, *The Pipe* (1924), the *British Museum Handbook to the Ethnographical Collection* (2nd ed 1925); the *British Museum Guide to the Maya Collection* (1923) (A D)

PIPIL, a dialect of the Nahuabl or Aztec language In southern Mexico, Guatemala and western Salvador there are four groups of Indians who speak a Nahua dialect, related to but more primitive than Aztec These four groups are. (1) *Pipil of Soconusco,* (2) *Pipil of the upper Motagua valley,* (3) *Pipil of Escuintla,* and (4) *Pipil of Salvador.* At the time of the Spanish conquest several explanations of the presence of these Mexican Indians in Central America were given by the natives. It was said that the Aztec emperor, Ahuitzotl (1486–1502), sent colonists to spy out the land and prepare for a never accomplished conquest This tale fails to account for the large and well-built cities occupied by the Pipil. More generally it is thought that they were Toltec (*q v*) who either migrated from Mexico with one of the early priest-kings named Quetzalcoatl, or, more probably, fled after the downfall of the Toltec empire in the 11th century. The Spanish historian Juan de Torquemada in support of the last hypothesis has preserved a significant migration legend Numerous ruined cities are attributed to the Pipil by archaeologists Of these the most important are Santa Lucia Cazumalhualpa and Baul in Gautemala and Chalchuapa, Cihuatan and Tehuacan in Salvador These sites yield characteristic stone carvings and pottery types. The present culture of the Pipil varies from village to village In general it reflects that of their neighbours such as the Quiché (*q v*)

PIPIT, a sub-family of birds having a great resemblance in habits and appearance to the larks (*q v*). They differ however in several important characters They are associated with the wagtails (*q v*) in the Passerine family *Motacillidae* Pipits, of which over 50 species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spraguii,* the prairie-lark of the northwestern plains, and *Anthus ludovicianus,* the American titlark which last is nearly allied to the water-pipit of Europe, *A. spipoletta* To English readers the best-known species is the titlark or meadow-pipit, *A. pratensis,* a bird abundant on pastures, moors, and uncultivated districts generally; but in some localities the tree-pipit, *A arboreus,* takes its place, and where it does so it attracts attention by its loud song, which is delivered (as in all the pipits) on the wing. Another species, the rock-pipit, *A. obscurus,* scarcely ever leaves the sea-coast and is found almost all round the British Islands. The South African genus *Macronyx,* remarkable for the extreme length of its hind claw, differs and has brighter coloration

PIPPIN or **PEPIN,** the name of three members of the Carolingian family.

back into the hand.

Pique.—If the elder hand scores, in hand and play, 30 or more, before the younger hand counts anything in that deal, he gains a *pique,* for which he scores 30.

Repique.—If a player scores in hand alone 30 or more before his adversary reckons anything, he gains a *repique,* for which he adds 60 to his score. Equalities do not prevent piques or repiques. A player who has an equal point or sequence scores nothing for it. Therefore if, notwithstanding the equality, a player makes 30, in hand and play, or in hand, by scores which reckon in order before anything his adversary can count, he gains a pique or a repique.

The order in which the scores accrue is of importance. For the sake of convenience, the elder hand finishes his reckoning before the younger begins. The scores, however, whether made by the elder or younger hand are recordable in the following order. (1) *carte blanche;* (2) point; (3) sequences; (4) quatorzes and trios; (5) points made in play; (6) the cards. This will often affect a pique or repique. Thus, a pique can only be made by the elder hand, as the one he reckons in play when he leads his first card counts before points subsequently made in play by the younger hand. The younger, therefore, cannot make 30 in hand and play before the elder scores one But the one reckoned by the elder hand when he leads his first card does not prevent his being repiqued, because scores made in hand have precedence of points made in play. The elder leads his first card and counts for it before the younger reckons, simply as a convenient way of stating that he has nothing in hand which is good. Again, say A has a quint (good), a tierce, and a quatorze (good). He scores 32 in hand alone; but, if his point is not good, he does not gain a repique, because the younger hand's point is recordable in order before the sequences and quatorze. *Carte blanche,* taking precedence of all other scores, saves piques and repiques. It also counts towards piques and repiques A *capot* does not count towards a pique, as the *capot* is not made in play. It is added after the play of the hand is over. A player who reckons nothing that hand as a penalty is not piqued or repiqued if he holds any cards which, but for the penalty, would have reckoned before his adversary reached 30. The game most commonly played now ("short game") consists of 4 hands only, the last and first being doubled, and 100 points added for the game.

See "Cavendish," *The Laws of Piquet and of Rubicon Piquet, adopted by the Portland Club, with a Treatise on the Game* (1882), "Cavendish," *Guide to Piquet* (1898); R. F. Foster, *Hoyle's Games* (1928). (W. DA)

PIRANDELLO, LUIGI (1867–), Italian dramatist and novelist, was born on June 28, 1867, on a country estate near Girgenti (Sicily). He first went to Rome at the age of 19, staying there until 1891, when he went to Germany and graduated in philosophy at the University of Bonn. He subsequently returned to Rome and taught at the girls' high school until 1923 His first literary essays were in verse, a volume entitled *Mal giocondo* published in 1889, followed by a poem *Pasqua di Gea* (1891) and *Elegie renane* (1895). Another Sicilian writer, Luigi Capuana, persuaded him to devote himself to fiction, and in 1894 he published his first novel, *L'esclusa,* in which his somewhat bitter realism already finds expression. Besides the novel, *Il turno,* he began to publish short stories: *Amori senza amore* (1894) *Quando ero matto* (1903), *Beffe della morte e della vita* (1902, 1903), *Bianche e nere* (1904), etc. In 1904 his most celebrated novel, *Il fu Mattia Pascal,* appeared, the story of a man, who having shammed being dead, tries in vain to begin his life anew in a different atmosphere and under another name. Other collections of short stories followed: *Erma bifronte* (1906), *La Vita Nuda* (1910), *Terzetti* (1912). He set forth his artistic creed in two volumes entitled *Arte e scienza* (1908). In 1913 his novel, *I vecchi e i giovani,* describing the drama of Italian life after the Risorgimento, was published in the *Rassegna contemporanea.* Other volumes of short stories appeared between 1914 and 1926, such as *La trappola* (1915), *Un cavallo nella luna* (1918), *Il carnevale dei morti* (1919), *Tu ridi* (1920), and another novel *Uno, nessuno e centomila* was published in the *Fiera letteraria.*

In 1920 he said of his own art:—

I think that life is a very sad piece of buffoonery; because we have in ourselves, without being able to know why, wherefore or whence, the need to deceive ourselves constantly by creating a reality (one for each and never the same for all), which from time to time is discovered to be vain and illusory . . . . My art is full of bitter compassion for all those who deceive themselves; but this compassion cannot fail to be followed by the ferocious derision of destiny which condemns man to deception.

This despairing outlook attained its most vigorous expression in Pirandello's plays. In his youth he had shown a certain contempt for the drama, but in 1912 he was persuaded by the Sicilian playwright, Nino Martoglio, to dramatize one of his own short stories, *La Morsa,* as a one-act piece. His first three-act comedy, *Se non così* (1917), was produced by Marco Parga at Milan in 1913; and then many plays—dramas and comedies—of which the most celebrated are *Il berretto a sonagli; Liola* (1917); *Così è se vi pare* (1918); *L'uomo, la bestia e la virtù* (1918); *Ma non è una cosa seria* (1918); *Come prima, meglio di prima* (1920); *Sei personaggi in cerca d'autore* (1921); *L'imbecille; Enrico IV.* (1922); *Vestire gli ignudi* (1922); *La vita che ti diedi; L'altro figlio; Ciascuno a suo modo; La sagra del signore della nave; La giara.*

Pirandello's dramatic art was at first criticized for being too "cerebral," for not seeing life as it really is and for arbitrarily deforming it. The Roman critics first discovered the real meaning of Pirandello's ideology and the human sense of his plays. His main themes are the necessity and the vanity of illusion, the multiform appearances, all of them unreal, of what is presumed to be the truth, man is not what he thinks he is, but he is "one, no one and a hundred thousand," accordingly as he appears to this person or to that, and is always different from what he creates himself in his own mind. Hence the supreme catastrophe, when a moral looking-glass suddenly reveals to him the image of himself which others see, *i e.,* what he *is* to others. Most of Pirandello's plays deal with a lower middle class milieu, peopled with clerks, teachers, lodging-house keepers, etc., from whose modest vicissitudes he draws conclusions of vast human significance. Typical is *Cosi è se vi pare,* in which he proves that it is impossible to know the real truth. *Enrico IV.* develops in a broader sense; that is, a drama in which we have a man who renounces his changing, empty and vain existence to play the part of a madman, and pretends to believe himself an historical personage, Henry IV. All this might be merely theatrical trickery if it were not seared by a deep anguish, characterizing a philosophy which has destroyed all faith in the absolute, in reality, in any fixed limits outside individual personality.

Pirandello's plays have rapidly achieved success throughout Italy and abroad, and have been translated into some 15 languages. In 1925 he created an art theatre of his own in Rome, where new Italian and foreign plays are performed, and in the summer of the same year he brought his company on a tour to England to produce his own plays in London (at the New Oxford theatre), to Paris, Basle and 18 theatres in Germany. Everywhere he met with an enthusiastic reception. (S. D'A.)

See W Starkie, *Luigi Pirandello* (1926) and F. Pasini, *Luigi Pirandello* (1927, bibl.).

PIRANESI, GIOVANNI BATTISTA, Italian engraver, was born in the earlier half of the 18th century. He was a Venetian who settled in Rome, where he devoted himself to engraving the ancient monuments. The explanatory texts engraved on many of his plates prove that his work was inspired by archaeological interest; but he was more artist than archaeologist

The most important of his publications are: *Antichità Romana de' Tempi della Repubblica* (1798); *Le Antichità Romane,* 4 vols. (1756); *Della magnificenza ed architettura de' Romani* (1761); and *Vedute di Roma* (135 plates engraved between 1748 and 1778, with two plates added later by F. Piranesi). He developed a powerful manner of etching. In his foregrounds the broad lines are strengthened with the graver. He achieves bold contrasts of tone which justify the large scale of his prints. Among his finest plates are the fanciful compositions in the *Opere Varie di Architettura* (1750) and in the *Carceri* (1750). He died in 1778.

PIRANO, a seaport of Istria, Italy, in the province of Pola,

22 m. S.W. of Trieste by rail. Pop. (1921) 7,665 (town), 14,158 (commune). It has picturesque Venetian walls and buildings. On the coast near are extensive salt pans. The Venetians defeated the fleet of Frederick Barbarossa off Pirano in 1177. It surrendered to Venice in 1283 and was incorporated with Austria, together with the rest of Istria, in 1813. It was the birthplace of the violinist Tartini. Near Pirano is the favourite seaside resort of Porto Rose.

PIRATE and **PIRACY.** Sir J. Fitzjames Stephen in his *Digest of Criminal Law* defined piracy as follows: "Taking a ship on the High Seas or within the jurisdiction of the Lord High Admiral from the possession or control of those who are lawfully entitled to it and carrying away the ship itself or any of its goods, tackle, apparel or furniture under circumstances which would have amounted to robbery if the act had been done within the body of an English county." (*Cf. A. G. for Hong-Kong* v. *Kwok-a-Sing,* 1873, L.R. 5 P.C. 179.) Piracy, being a crime not against any particular State but against all mankind, may be punished under international law in the competent court of any country where the offender may be found or into which he may be carried. But, whilst the practice of nations gives to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state), they may not be killed without trial except in battle. Those who surrender or are taken prisoners must be brought before the proper tribunal and dealt with according to law.

Following the sinking of merchant vessels at sight by German submarines in the World War, by the Washington Treaties (1921–22) between the United States, the British Empire, France, Italy and Japan, attacks upon, and destruction of, merchant vessels upon visit and search by any person in the service of any Power were declared acts of piracy, and such persons may be brought to trial before the civil or military authorities of any Power within the jurisdiction of which he may be found. It was held by the Federal District Court of New York, in the suits brought against the Cunard Steamship company for damages arising out of the sinking at sight of the "Lusitania" by a German submarine, that such sinking was an illegal act. See *The Lusitania* (1918) 251 Fed. 715; *Scott's Cases,* 784–90. (X.)

HISTORY

It is impossible to say at what period in the world's history piracy began. References to this form of robbery occur in early literature. It was rampant in the Mediterranean in the days of the Roman republic, and it is recorded that Julius Caesar, when a young man, fell into the clutches of a gang of sea-robbers who held him prisoner until ransomed, and that after his release he returned with some soldiers who captured his late gaolers and crucified the whole crew. Amongst the early pirates of which records still exist are the Phoenicians, while there are numerous references to sea-rovers in the Odyssey. Out of the dim North, the Vikings (*q.v.*) are known to have come south to plunder the coasts of Britain, Ireland and France, in A.D. 789 and onwards. For many centuries the north-east coast of Africa was the headquarters of the Barbary pirates (*q.v.*) or Moors, as they were commonly called, who had their chief strongholds at Algiers, Sallee and Tripoli. From these harbours they sailed out to harry passing ships, or plunder the opposite coast of Spain, carrying back their Christian captives to sell as slaves. In spite of numerous punitive attacks, these fierce sea-robbers were not finally stamped out until 1830. All through the Tudor reigns piracy was rampant around the British isles, particularly in the south of Ireland and in the Scilly isles, where safe retreats existed for the pirate and where receivers of plunder were to be found willing to buy the goods that the pirate had to offer.

As in the case of the land thief, the sea thief could not exist without a market for his ill-gotten goods. It would be useless for a pirate to seize a well-laden merchant ship, if he had nowhere he could dispose of his prize. Sir William Monson in his book *Naval Tracts,* records how he was sent in 1605 to search for pirates in the Shetlands and Hebrides. But it was in Ireland where he found what he looked for. At Broad Haven he met with an Irish gentleman, of the name of Cormat or Cormac, whose house he describes as being the "well-head of all pirates." Here the Irishman lived in great style and trafficked with the pirate captains, many of whom were the lovers of his daughters.

As life became more difficult for the pirates in the home waters, they migrated further afield, where they could practise their calling with less interference. Thus piracy spread to the far-off West Indies, and the coast of New England, and eventually to the Red sea and Madagascar. For many years the latter island was the happy haunt of the pirates, where they lived in security, married native women, and reigned as petty kings. From here they were able to lay heavy toll on passing ships sailing between England and the East Indies.

The natural haunts of the pirates were in archipelagos and indented coasts, and there at one time or another such places as the Greek islands, the Indian ocean, the coast of Cilicia, the British Isles, Norway and the West Indies became their lurking places.

In England itself, up to the 16th century, piracy was not uncommon, and it was no unusual event for the inhabitants of the Cinque ports to sally forth in their small ships and plunder any passing vessel, and on more than one occasion the fleet of New Romney attacked and plundered the ships of its rival, Yarmouth.

The West Indies.—The West Indies were well prepared for practical exploration both geographically and historically. Since the 16th century the buccaneers (*q.v.*) had preyed upon the Spaniard, and there were innumerable hiding-places, hidden bays in uncharted islands, where pirates could meet in safety and divide the spoils and prepare for their next adventure. During the 17th century the island of Tortuga, or Turtle island, off the coast of Hispaniola, became a regular pirate republic. Good markets for stolen plunder were to be found on the New England coast, and in Jamaica and at New Providence island, as well as in Ireland and certain places in the west of England.

Much of the piracy in the West Indies and America was the direct outcome of the Spanish policy of forbidding her colonists the right of trading with foreigners, in spite of her inability to supply their needs herself. Naturally the Spanish Americans were only too eager to buy smuggled goods, at very low prices, and were not likely to be very particular to enquire where the goods came from. England and France also tried to insist on their colonists trading exclusively with themselves, at their own prices, which, combined with the almost total lack of policing by the regular navies, led to wholesale buying of smuggled merchandise, procured by irregular methods. It was not until the reign of William III., about 1700, that workable laws were made for trying pirates, and even then it was often difficult to get a jury to condemn a pirate who was looked upon as a public benefactor. Owing to the difficulty of policing the seas, particularly in distant waters, the custom arose in the reign of Charles I., and continued until that of George I., of granting free pardons to all pirates who would surrender themselves by a certain date. The result was that when things had become too warm for a pirate, he would make his submission to the authorities and receive the royal pardon, and, as soon as ever his booty was spent, resume his old practices. One of the greatest wholesale pardoning of pirates was carried out by Captain Woodes Rogers at New Providence in the Bahamas in 1718. At this time there were more than 2,000 freebooters entrenched in this pirate stronghold, but Rogers dealt so successfully with them that almost all surrendered.

Organization.—The ranks of the pirates were recruited from a type of seafaring man who disliked steady work with its small rewards, and preferred a life of danger, with a prospect of gaining sudden wealth. After every European war ships would be laid up and crews disbanded. There being no honest employment for all these sailors, they were compelled by circumstances to take any employment at sea that offered itself; and as often as not this consisted of signing on in a ship where no questions were asked, and no wages paid, but where every member of the crew took a share of any profits which might accrue from the voyage.

Very often when a pirate captured a merchant ship the crew of the latter were invited to join the pirates. Some would do so

willingly, others only under compulsion. Most pirates when brought to trial pleaded that they had been compelled to join the pirates, and had done so only to save their lives. It often happened that amongst the members of a captured crew there would be some "sea-artist," as a particularly skilful navigator was called, and he would be compelled to sign on whether he wished to or not. A common source of piracy was the privateer, an armed ship that sailed under a letter of marque, which was apt to drift into piracy, when its legitimate prey was not forthcoming, to supply the prize-money which paid the wages of officers and crew. This fact was pointed out by Cotton Mather (*q.v.*), the New England divine, in one of his "hanging sermons" delivered at Boston to condemned pirates. In one which he preached in 1704 called "A Brief Discourse occasioned by a Tragical Spectacle of a Number of Miserables under Sentence of Death for Piracy," he stated, "the Privateering Stroke so easily degenerates into the Piratical, and the Privateering Trade is usually carried on with an Unchristian Temper, and proves an Inlet into so much Debauchery and Iniquity."

The same view was expressed by Nelson when he declared that all privateers were no better than pirates, although this wide accusation cannot be allowed to include such famous and patriotic privateers as Captain Fortunatus Wright or Commodore Walker. Many a shady privateer was little better than a pirate, and the letter of marque under which he sailed a mere pretence, as in the case of a pirate who plundered Spanish ships in the 17th century, under a commission sold to him by the governor of a Danish West India island, himself a reformed pirate. This document, written in Danish, proved, when translated, to entitle the holder to hunt for goats and wild pigs on the island of Hispaniola and nothing more.

The establishment of a pirate gang usually took one of two forms. The most usual was for a few ringleaders to plot a mutiny on board a merchant ship. At a prearranged signal the mutineers would seize the officers and kill them and any members of the crew who resisted, and throw their bodies overboard.

But many a pirate who eventually rose high in his profession began in a very small way. Often a handful of desperate characters would steal a boat and row or sail along the coast by night, until they surprised the crew of some small schooner, and became masters of her. In this they would venture further afield, until by cunning or force they got possession of a larger ship. The downfall of most pirates was brought about by their utter lack of discipline, for, unless the elected captain was a man of unusual strength of character, as was the famous Captain Bartholomew Roberts, he was unable to keep his crew in order, and sooner or later, disaster overtook them, through careless navigation or at the hands of a better-disciplined hostile ship.

One of the first formalities of a newly created pirate crew was the drawing up and signing of the ship's articles, which would include such rules as the following, taken from those of Captain John Phillips of the "Revenge":

1. Every man shall obey civil Command; the Captain shall have one full Share and a half in all Prizes; the Master, Carpenter, Boatswain and Gunner shall have one Share and a quarter.

6. That Man that shall snap his Arms, or smoak Tobacco in the Hold without a cap to his Pipe, or carry a Candle lighted without a Lanthorn, shall receive Moses's Law (that is 40 Stripes lacking one) on the bare Back.

9. If at any time you meet with a prudent Woman, that Man that offers to meddle with her, without her Consent, shall suffer present Death.

Another matter, considered to be of great importance, was the choice of a flag, whose chief object was to "strike terror into all beholders." The favourite design was a skull and cross-bones; though sometimes a whole skeleton was depicted, holding in one boney hand a rummer or glass of punch, and in the other a sword or dagger. Whenever possible the pirates carried a surgeon, who was treated with a certain amount of respect.

Famous Characters.—The ordinary pirate was merely a criminal who lived for himself alone, and lacked any sense of ambition other than to get rich quickly, and must not be placed in the same category with the Vikings, who although sea-robbers and murderers, worked in large and, to a certain extent, organized bands; as did the Mediterranean pirates in Roman times who formed a highly organized brotherhood of desperadoes. The ordinary pirates boasted that they "declared war upon the whole world" and possessed no honour even amongst themselves.

A few of the most famous pirates may be briefly mentioned. Captain John Avery, *alias* Every, *alias* Bridgeman, familiarly known as "Long Ben" or the "Arch-Pirate," was born at Plymouth about 1665, took to the sea and rose to mate in a merchant ship; headed a mutiny and was elected captain; proved himself a daring pirate leader, and after much success off the Guinea coast and in the West Indies sailed to the Red sea, where he seized a rich ship of the Great Mogul, reported to have on board 100,000 pieces of eight and the Mogul's young and lovely daughter. He took both to Madagascar where he settled down as a reigning monarch. In 1696 he was at Boston, where he bribed the governor to allow him and his crew to land and dispose of their plunder. He died in poverty at Bideford after being tricked out of his ill-gotten gains by certain merchants of Bristol. Charles Johnson wrote a play called *The Successful Pyrate,* which was acted at Drury Lane, in 1713, and which was modelled on Avery's career.

Bartholomew Roberts was, perhaps, the greatest of all pirates. Born in Wales in 1682, he died fighting in 1722. He was credited with having taken over 400 ships during his career, and was remarkable for his discipline, for being a teetotaler, and allowing no women or gambling aboard his ships.

Edward Teach, *alias* Blackbeard, a picturesque blackguard, was killed on Nov. 17, 1718, in a hand-to-hand combat with Lieut. Robert Maynard, of H.M.S. "Pearl."

Captain Misson, a Frenchman of good family, was unique in combining active piracy with socialistic ideals. He reigned for many years over a Utopian republic in Madagascar.

Two women pirates, Anne Bonny and Mary Read, deserve mention, as both rose high in their ancient dual professions.

The famous Captain Kidd was no pirate at all, but the victim or scapegoat of political intrigue.

With the peace of 1815 came a great increase in West Indian piracy, which was assisted by the inability of the Spanish authorities to cope with the pirates while their colonies were seething with revolt. At last the British and American navies combined to root out the evil once and for all in the Atlantic, although piracy lasted in the Greek islands until nearly 1850.

The end of piracy, after centuries, was brought about by public feeling, backed up by the steam-engine and telegraph. The last relic exists to-day in China, where a nest of troublesome pirates still carries on the old trade in spite of the navies of the foreign powers. The Chinese pirates ship themselves as ordinary coolie passengers on a coastal steamer and, at a given signal, produce revolvers and hold up the officers and crew and compel them to navigate the ship to their headquarters at Bias bay, where the ship is plundered and officers and passengers held for ransom.

BIBLIOGRAPHY.—Mommsen's *History of Rome;* Monson's "Naval Tracts" in *Churchill's Voyages,* v., 5 (London, 1744–46), and in Navy Record Society (1902); *State Trials,* vols. xiii., xiv., xv. (London, 1812); Captain Charles Johnson's *General History of the Pyrates* (1724) gives full and accurate details of the lives, activities and death of the most notorious pirates of the early 18th century; and a second volume, published in London in 1726, does the same for the Madagascar pirates. It used to be said that Charles Johnson was inaccurate and unreliable, but recent research has proved again and again that, whoever he was, he had first-hand knowledge of his subject and is to be relied upon in almost every detail. Edmonds, *The Pirates of the New England Coast* (1630–1730). *See* also Publications of Marine Research Society, Salem, Mass., 1923.

(P. Go.)

PIRELLI AND CO. and SOCIETÀ ITALIANA PIRELLI OF MILANO, Italy, are now one of the largest industrial organisations throughout all Italy, with a large number of international ramifications, employing at the end of 1928 over 30,000 hands all over the world, specialising in the manufacture of electric cables, tyres of all descriptions and general India-rubber and gutta-percha goods. Founded in 1872 by Ing. Giovanni Battista Pirelli, at present a member of the Italian Senate and president of the company, they have gradually increased in

importance, developing large factories in Italy (Milano, Bicocca, Spezia and Vercurago), Spain (Villanueva y Geltrù and Manresa) and in the Argentine (two factories in Buenos Aires).

Pirelli-General Cable Works, Ltd., 144, Queen Victoria Street, London, E.C.4., with factories in Southampton and Eastleigh, England, are among the most prominent British manufacturers of electric cables; Pirelli, Ltd., own a large factory on a site of 63 acres at Burton-on-Trent, manufacturing pneumatic, semi-pneumatic and solid tyres; these English factories employ British labour throughout.

Another Pirelli company owns large rubber plantations at Boenisari, Isle of Java. Financial and commercial Pirelli companies operate from Barcelona, Brussels, Bucharest, Copenhagen and Paris, and Pirelli agents are active in practically every commercial centre throughout the world. Pirelli also own, or have controlling interests in, cotton-spinning and weaving mills, copper drawing mills and other branches of industry.

Among the lines in which the Pirelli companies specialise should be mentioned submarine telegraph cables laid across the Atlantic Ocean; high tension underground cables for abnormal working pressures, installed in New York and Chicago; pneumatic, semi-pneumatic and solid automobile, motorcycle and bicycle tyres. (M. S. L.)

PIRENNE, HENRI (1862–), Belgian historian, was born at Verviers on Dec. 23, 1862. He first lectured at the University of Liége, and in 1886 became professor at the University of Ghent. His *Histoire de Belgique*, of which five volumes had appeared in 1925, completely revolutionized the current conceptions of Belgian history and nationality by showing how, from the time of the Germanic invasions, Flemings and Walloons were drawn together by community of tradition and economic interest. Pirenne's works on mediaeval cities and social conditions include *Les anciennes démocraties des Pays-Bas* (1910, Eng. trans. 1915) *Recueil des documents relatifs à l'histoire de l'industrie drapière en Flandre* (with G. Espinas, 4 vol., 1906–24) and *Mediaeval Cities: Their Origins and the Revival of Trade* (Princeton, 1925). He was the first president of the "Union Académique Internationale" (1920–23) and received many foreign honours.

PIRKE ABOTH, lit. Chapters of the Fathers, a collection of proverbs arranged chronologically and giving a *catena* of Jewish scholars. The treatise belongs to the IVth Order (*Neziqin*) of the Mishnah and deals with the history of tradition. This, the so-called Oral Law (*Torah she-be-'al Peh*, Deut. iv. 14: v. 22–33, especially 31; and other passages) supplemented the Written Law (*Torah she-be-khethabh*). The Oral Law in Aboth is traced back from Moses, through Joshua, the elders and Prophets, to the Men of the Great Synagogue, a body the existence of which is now merely doubted but which was formerly denied categorically. Through Simon the Just (either Simeon grandson of Jaddua, High priest, 310–291 B.C., or his grandson, 219–199) and Antigonus of Socho, both survivors of the Great Synagogue, tradition is carried on by five pairs of teachers (*Zūgōth*, ζυγόν) to Hillal and Shammai (30 B.C.). Henceforward the sayings of their disciples and successors are given until ch. iv., which concludes with El'azarhaq-Qappar (end of 2nd cent. A.D.). Chapters iii. and iv. are not strictly chronological. Chapters v. and vi. are of later date. Chapter v. combines historical, legendary and didactic elements, miracles are explained and a series of things, sayings and qualities are grouped numerically, *e.g.*, ten *Ma'amaroth* or *Logoi* are said to have created the world; vi. is called the "chapter of the acquisition of the Law" and was probably added for liturgical purposes. Aboth is written in simple Hebrew. The aphorisms are of great intrinsic beauty and are of extreme historical importance not only for Judaism but for the environment of nascent Christianity. The chapters are read, on different occasions, in most Jewish rites.

BIBLIOGRAPHY.—Pirke Aboth may be studied in English in Singer's *Authorized Daily Prayer Book* pp. 184 *sqq.* I. Abrahams Notes (pp. clxxvi. of the *annotated edition* should be consulted). The reader is also referred (a) to the *Jew. Enc.* s.v. *Abot.* (b) *Abot* in *Encyclopaedia Judaica* vol. I. Berlin (1928). (c) R. Travers Herford's two editions (1) in R. H. Charles *Apocrypha and Pseudepigrapha*, vol. II. (1913) and (2) publ. by *Jewish Inst. of Religion Press* (1925), on which see S. B. Maximon's article on pp. 325 *sqq.* of *Jewish Studies in Memory of Israel Abrahams* (1927). The older editions of C. Taylor and H. Strack are still of great value.

PIRMASENS, a town of Germany, in the Bavarian Palatinate, 40 m. W. by S. of Speyer, on the railway from Biebermühle. Pop. (1925) 42,996. Pirmasens owes its name to a St. Pirmin, who is said to have preached Christianity here in the 8th century. It originally belonged to the count of Hanau-Lichtenberg, but passed to Hesse-Darmstadt in 1736. The staple industry is the production of boots and shoes; but organs, leather and machines are also manufactured.

PIRNA, a town in the republic of Saxony, on the left bank of the Elbe, 11 m. above Dresden, and on the railway to Bodenbach and Prague. Pop. (1925) 30,460. Pirna, originally a Slavonic settlement, was for many years in the alternate possession of Bohemia and Meissen, but it became permanently united with the latter, and thus with Saxony, in 1405. The most notable edifices are the Gothic parish church, built in the 16th century and restored in 1890, and the old town-hall. Excellent sandstone is found on both banks of the Elbe. There are manufactures of glass, machinery, cigars, pottery, slates and enamelled goods and cotton spinning and wood sawing. The Sonnenstein, a fortress on an eminence above the town, was erected in the 16th century.

PIROGUE or **PIRAGUA** (the French and Spanish forms respectively of a Caribbean word for this type of vessel; it has at various times taken many corrupt forms, *e.g.*, *periagua*, *pettiaugua*, *pettyoagar*), originally the native name of a vessel made by hollowing out the trunk of a tree, a "dug-out"; hence applied to many different developments of this type of vessel used in the West Indies and along the American coast. An early improvement was to split the "dug-out" into two sections and insert a flat bottom of planking to widen it; another form had a lee-board, was decked in at either end, and had two masts.

PIRON, ALEXIS (1689–1773), French epigrammatist and dramatist, was born at Dijon on July 19, 1689. His father, Aimé Piron, an apothecary, wrote verse in the Burgundian patois. Alexis began life as clerk and secretary to a banker, and then studied law. In 1719 he went to Paris. In that year jealousy of the regular actors produced an edict restricting the Théâtre de la Foire, or licensed booths at fair times, to a single character on the stage, and Piron made a great success with a piece called *Arlequin Deucalion*, representing Deucalion immediately after the Deluge. In 1728 he produced *Les Fils ingrats* (known later as *L'École des pères*) at the *Comédie Française*. He attempted tragedy unsuccessfully in *Callisthène* (1730), *Gustave Vasa* (1733) and *Fernand Cortès* (1744). Piron returned to comedy with *La Métromanie* (1738). His most intimate associates at this time were Mlle. Quinault, the actress, and her friend Marie Thérèse Quenaudon, known as Mlle. de Bar whom he married in 1741. He died on Jan. 21, 1773. His best title to remembrance lies in his epigrams. The burlesque epitaph on himself, in which he ridicules the Academy—

Ci-gît Piron, qui ne fut rien,
Pas même académicien

is well-known. Grimm called him a "machine à saillies."

Piron published his own theatrical works in 1758, and after his death his literary executor, Rigoley de Juvigny, published his *Oeuvres complètes*. M. Bonhomme produced a critical edition in 1859, completed by *Poésies choisies et pièces inédites* in 1879.

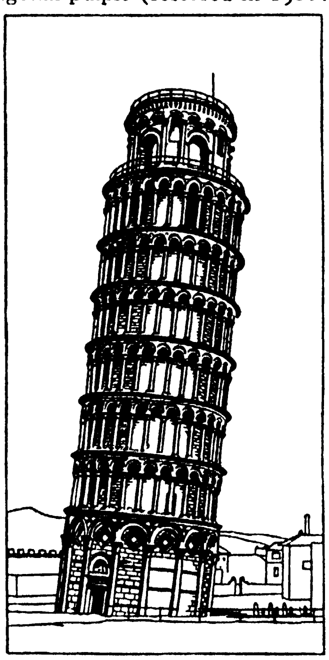
PIROT, a town of South Serbia, Yugoslavia. Pop. (1921) 10,462. It lies amid romantic scenery, and is the seat of a prefecture and a tribunal. The inhabitants are engaged in the manufacture of jewellery, thin cloth, woollen braid and carpets. The latter, woven on hand looms by women and children, are its speciality, and are noted for their excellent quality, designs and colouring. There are several schools, a large mosque and a curious old square leaning tower. The mediaeval fortress is believed to have been built on the site of the Roman fortress Quimedava, on the military road from Old Naissus (Nish) to Philippopolis. Outside the town is an early modern entrenched camp. Pirot, which is strategically important, was captured by the Serbs in the Russo-Turkish War (1877–78) and was ceded to Serbia by the Treaty of Berlin (1878). In the war between Serbia and Bulgaria in 1885 Pirot was

occupied by the Bulgarians and held by them till peace was signed.

PIRRIE, WILLIAM JAMES, 1st Viscount (1847–1924), British shipbuilder and engineer, was born at Quebec on May 31, 1847, and educated at Belfast Royal Academic institution. In 1862 he entered the shipbuilding firm of Messrs. Harland and Wolff of Belfast, becoming partner in 1874 and later chairman. His success was particularly associated with the building by his firm of the White Star line steamships, the first being launched in 1870. From 1896 to 1897 he was lord mayor of Belfast. In 1906 he was raised to the peerage as Baron Pirrie. In 1918, towards the close of the World War, he was made controller-general of merchant shipping. In 1921, on the King's visit to Belfast to inaugurate the new parliament of Northern Ireland, he was created a viscount. He died on June 6, 1924.

PISA, a town and archiepiscopal see of Tuscany, Italy, capital of the province of Pisa, on the Arno, 7 m. from the sea, and 49 m. W. of Florence by rail. Pop. (1921) 51,774 (town), 68,933 (commune). It retains its mediaeval walls, 6¼ m. in circuit; the citadel now contains barracks. The cathedral, the baptistery, and the famous leaning-tower form a group by themselves at the north-west corner of the town. The two former are built in black and white marble, a characteristic found in Pisan churches elsewhere also. (*See* Sardinia.)

The architects of the cathedral were Buschetto and Rinaldo, both probably Pisans. The church is in plan a Latin cross, 311½ ft. long and 252 ft. wide across the transepts inside. The nave, 109 ft. high, has double, the transepts single, vaulted aisles: and at the intersection of nave and transepts is a dome. The columns of the nave and side aisles are ancient. The west front is the finest part of the exterior: the range of arches running round the base is repeated by four open arcades. The three bronze doors were re-made after the fire of 1596; that of the south side (1180) is by Bonanno. The mosaics in the apse were designed by Cimabue, and the splendid decagonal pulpit (restored in 1926: see *Per la recostruzione del pergamo di Giovanni Pisano,* 1926) is by Giovanni Pisano. The baptistery, begun in 1153, is a circle 100 ft. in diameter and is covered with a cone-surmounted dome 190 ft. high on which stands a statue of S. Ranieri. The lowest range of semicircular arches consists of 20 columns, and the second of 60; and above this is a row of 18 windows in the same style separated by as many pilasters. In the interior, which is supported by four pilasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Niccola Pisano. The campanile or "leaning tower of Pisa," begun by Bonanno in 1174, is round. The walls at the base are 13 ft. thick, and at the top about half as much; they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by 15 columns, and above this rise six arcades with 30 columns each. The eighth storey, which contains the bells, is of much smaller diameter than the rest of the tower, and has only 12 columns. The height of the tower is 179 feet. The tower was 15½ ft. out of the perpendicular when measured in 1829, and 16½ ft. in 1910. There is no reason to suppose that the architects intended that the campanile should be built in an oblique position; it would appear to have assumed it while the work was still in progress. The foundations are not more than 10 ft. deep, and their circumference only that of the tower. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo (1188–1200) who made the spot peculiarly sacred by bringing 53 shiploads of earth from Calvary. The building, erected in the Italian Gothic style by Giovanni Pisano in 1278–83, is of special interest for its famous frescoes by various Tuscan artists, including a "Last Judgment" by Francesco da Volterra after Orcagna (1370–71); Benozzo Gozzoli (23 Old Testament scenes, 1468–84), and also for the large collection of Roman sculptures which it contains. Other notable churches are: S. Andrea, S. Pierino, S. Michele in Borgo (11th century), S. Sepolcro, erected by Diotisalvi (*c.* 1150), S. Nicolò, with a four-storied tower (*c.* 1230), S. Caterina (1252), S. Francesco (13th century) with frescoes by Taddeo Gaddi (in the adjacent monastery is the interesting museum and picture gallery); S. Maria della Spina, an elegant little church of white marble (1325–29); and the Renaissance church of the Tuscan order of St. Stephen from plans by Vasari (after 1562), who also reconstructed the palace of the order.



THE LEANING TOWER OF PISA
Begun in 1174 and completed in 1350, the campanile is 179 ft. high and leans more than 16 ft. out of the perpendicular

The main streets of the older part of the town have porticoes. There are wide quays, with fine buildings, on each side of the Arno, but the town, as a whole, is quiet, owing much of its importance to its being the junction for Florence, Lucca, and Volterra, on the main line between Rome and Genoa. The university, founded in 1338, had 1,096 students in 1925–26; it has a natural history and other museums and a botanical garden. There is also an engineering school (103 students), a veterinary institute (114 students), and an agricultural institute (109 students). In the vicinity are the royal villa and stud-farm (horses and dromedaries) of San Rossore (the name is a corruption of Lussorio, *see* Fordungianus), and the mineral baths of San Giuliano, alkaline-ferruginous, with temperature 91·4° to 105·8° F. At the mouth of the Arno, joined to the city by a steam tramway (on the way is the old church of S. Piero in Grado) is the seaside resort of Marina di Pisa, also known as Bocca d'Arno, a well known centre for landscape painters. At Navacchio, 5 m. E. of Pisa, is a biscuit factory, 4 m. N. of which is Calci, and near it the large monastery of the Certosa di Pisa.

The ancient Pisae on the right bank of the Arno was only 2 m. from the sea, the delta having increased since. It is believed to have been founded from Pisae in Elis and is first mentioned in history as the place at which a Roman army from Sardinia landed in 225 B.C. Being situated on the coast road (Via Aemilia), it was important as a frontier fortress against Liguria, for the fertility of its territory, and its quarries and timber for shipbuilding. Scanty ruins of Roman baths exist near the modern Lucca gate on the north. The older town occupied the same site. (T. A.)

HISTORY

Little is known of Pisa during the barbarian invasions, but it is an ascertained fact that it was one of the first towns to assert its independence of Byzantine rule. During the first years of the Lombard rule the necessity of defending the Italian coast from the attacks of the Byzantines was favourable to the development of the Pisan navy.

Early Wars.—In 1003 we find records of a war between Pisa and Lucca, which, according to Muratori, was the first waged between Italian cities in the middle ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. Numerous legends and fables of the old chroniclers serve to attest the importance of Pisa in those days. The Saracens repeatedly attacked the town, but were repulsed, and the Pisans themselves assumed the offensive in Calabria, Sicily, and even in Africa. In 1015 a memorable expedition was undertaken by the united forces of Pisa and Genoa against Mogahid, better known in the Italian chronicles as Mugeto, whom they drove from Sardinia. Again invading the island, he was again attacked and defeated by the same adversaries, leaving a brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by native "judges" who were like petty sovereigns, but were now subject to the sway of Pisa. This was

the primary cause of the jealousy of the Genoese and of the wars afterwards made by them upon Pisa. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di mare*), which in 1075 were approved by Gregory VII., and in 1081 confirmed by a patent from the emperor, Henry IV. The oldest of Pisan statutes still extant is the *Breve dei consoli di mare* of 1162.

Commercial Prosperity.—In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses and privileges of all kinds in every Eastern port. Thus while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese and Muslims. In the years 1113 and 1115 it achieved a still greater enterprise. The Pisan fleet of 300 sail, commanded by the archbishop, Pietro Moriconi, attacked the Balearic Isles, where as many as 20,000 Christians were said to be held captive by the Muslims and returned loaded with spoil and with a multitude of Christian and Muslim prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. Immediately afterwards, the 14 years' war with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan Church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese Church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor, Lothair II., the Pisans entered Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Muslims (1187) the Pisans and Genoese again met in conflict in the East, and it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistry was begun in 1152, and the campanile (the famous leaning tower) in 1174 And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

RIVALRY WITH FLORENCE AND GENOA

The chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelph and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. Owing to the political and commercial interests binding Florence to the Roman court, the Guelph element naturally prevailed there, while growth of its trade and commerce necessarily compelled that republic to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a vigorous resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies The chroniclers ascribe the first war with Florence, which broke out in 1222, to a ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog—which merely shows that there were already so many general and permanent reasons for war that no special cause was needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garfagnana, and at the same time they despatched 52 galleys to assist Frederick II in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia, and war was intermittent down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca and all the Guelph cities of Tuscany against its Ghibelline rival: the pope had excommunicated Frederick II. and all his adherents; and, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless the Pisans were undaunted. Summoning Siena, Pistoia and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254 Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now 12 elders (*anziani*); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of 40 members. The rout of the Tuscan Guelphs on the field of Montaperti (1260) restored the fortunes of Pisa But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), sealing the ruin of the house of Hohenstaufen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins The internal condition of the city was affected by these events Owing to the increasing influence of the Guelph and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. At this time Count Ugolino della Gherardesca had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the Guelphs and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman, Giovanni Visconti, judge of Gallura, in Sardinia; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor. In 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid waste its surrounding territories In 1276 the Pisans were compelled to agree to very grievous terms—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On Aug 6, 1284, at the great battle of Meloria 72 Pisan galleys engaged 88 Genoese, and half the Pisan fleet was destroyed The chroniclers speak of 5,000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa She had lost her dominion over the sea, and the Tuscan Guelphs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery At the height of his country's disasters he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself This excited a storm of opposition against him. The archbishop, Ruggieri, having put himself at the head of the nobles, was elected podestà by the Lanfranchi, Sismondi and Gualandi, and a section of the popular party. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After

a day's fighting (July 1, 1288) the count, his two sons and his two grandsons were captured in the palazzo del popolo (or town hall), and cast into a tower belonging to the Gualandi, and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic prelate opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. In 1293 they secured a profitable peace. They and the other members of the Guelph league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba were exempted from every tax. They likewise received a ransom of 160,000 florins for their Pisan prisoners.

In 1312 the arrival of the Emperor, Henry VII., gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Uguccione della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on Aug. 29, 1315. In 1316, however, he was expelled in an outburst of popular fury. But Pisa's freedom was forever lost. Uguccione della Faggiuola was succeeded by other lords or tyrants of whom the most renowned was Castruccio Castracane, a political and military adventurer of much the same stamp as Uguccione himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them forever—but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (Oct. 2), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them in triumph to Florence, and suspended them in front of the baptistery, where they remained until 1848. Then in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Giovan Galeazzo Visconti, known as the count of Virtù, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Gherardesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtù, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa and Monte Cristo. Thus in 1399 Visconti took possession of Pisa, and left it to his natural son, Gabriele Maria Visconti, who was afterwards expelled from its gates. But even in this century of disaster the Pisans continued to encourage not only commerce, but also the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Nicola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and the celebrated frescoes attributed to Orcagna (*q.v.*) were painted on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1464.

The Victory of Florence.—Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on Oct. 9, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner course. In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not hesitate, even in his presence, to assert their own independence, and casting the Florentine emblem, the Marzocco, into the Arno, made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault, and, what was worse, yearly laid waste their territories and destroyed all their crops. Soderini, who was perpetual gonfalonier of Florence, and Machiavelli, the secretary of the Ten, urged on the war. In 1509 Florence encamped her forces on three sides of the distressed city, which at last, reduced to extremity by famine, was compelled to surrender on June 8, 1509. Thenceforth the Florentines remained lords of Pisa. But now, mainly owing to the efforts of Soderini and Machiavelli, the conquerors showed great magnanimity. They brought with them large stores of provisions which were freely distributed to all; endeavoured to succour the suffering populace in every way, and gave other assistance to the wealthier classes. Nevertheless, emigration continued even on a larger scale than in 1406, and the real history of Pisa may be said to have ended. In Naples, in Palermo, in all parts of Italy, Switzerland and the south of France, we still find the names of Pisan families who quitted their beloved home at that time. The Florentines immediately built a new citadel, and this was a great bitterness to the Pisans. The Medici, however, remained well disposed towards the city. Leo X. was an active patron of the university, but it again declined after his death. The grand duke, Cosimo I., a genuine statesman, not only restored the university, but instituted the "uffizio dei fossi" or drainage office for the reclamation of marsh lands, and founded the knighthood of St. Stephen. This order played a noble part in the protection of Tuscan commerce, by fighting the Barbary pirates and establishing the prestige of the grand-ducal navy (*see* MEDICI). Under the succeeding Medici, Pisa's fortunes steadily declined. Ferdinand I. initiated a few public works there, and above all restored the cathedral, which had been partly destroyed by fire in 1595. These dreary times are brightened by one glorious name—that of Galileo Galilei.

PISA, COUNCIL OF (1409). The great schism of the west had already lasted thirty years, and the efforts which had been made to restore unity within the Church by the simultaneous resignation of the two rival pontiffs had been in vain, when in the spring of 1408, the state of affairs being desperate, the idea arose of assembling a council to effect a union without the co-operation of the popes. The initiative came from those cardinals who had one after the other seceded either from Gregory XII. or Benedict XIII. The day after the opening of the council, proceedings were started against the two popes, who, it was agreed, were to be eliminated. In order to depose them with some show of legality, it was necessary, as a preliminary, to convict them of heresy, and it began to be seen that their tenacity of power, and the ruses by which they evaded the necessity of abdicating, however harmful might be their consequences, did not in themselves constitute a clearly-defined heresy. On the 5th of June 1409 was read the definitive sentence: that as heretics, and therefore separated from the Church, Pedro de Luna (Benedict XIII.) and Angelo Corrario (Gregory XII.) were *ipso facto* deposed from any office; they must not be obeyed, nor assisted, nor harboured.

In order to complete their task the cardinals present at Pisa, authorized by delegation of the council, shut themselves up in conclave, and elected one of their number, Peter Philarges, cardinal of Milan, as the new pope, who assumed the name of Alexander V. They had hoped to save the Church, but unfortunately the result of their efforts, generous as they were, was that the schism increased in bitterness, and that instead of the unity for which the Church craved, three popes continued to flourish. Both the deposed pontiffs protested against the legality of the council of Pisa; each had numerous partisans, and the thesis, constructed rather to meet the exigencies of the case, which attributed to a synod assembled by the cardinals the right of constituting itself judge of a sovereign pontiff, was far from being established. The council was proceeding to occupy itself with reform when it was dissolved by Alexander V. (August 1409).

PISAN, CHRISTINE DE (1364–*c.* 1430), French poet, of Italian birth, was born at Venice in 1364. When she was four years old she was brought to her father, a councillor of the Venetian Republic, in Paris, where he held office as astrologer to Charles V. At fifteen Christine married Étienne du Castel, who became Charles's notary and secretary. After the king's death in 1380 her father lost his appointment, and died soon after; and when Christine's husband died in 1389 she found herself without a protector, and with three children depending on her. This determined her to have recourse to letters as a means of livelihood. Her first ballads were written to the memory of her husband, and as love poems were the fashion she continued to write others—*lais, virelais, rondeaux* and *jeux à vendre*—though she took the precaution to assure her readers (*Cent balades*, No. 50) that they were merely exercises. In 1399 she began to study the Latin poets, and between that time and 1405, as she herself declares, she composed some fifteen important works, chiefly in prose, besides minor pieces.

The earl of Salisbury, who was in Paris on the occasion of the marriage of Richard II. with Isabella of France (1396), took her elder son, Jean du Castel (b. 1384), and reared him as his own; the boy, after Salisbury's death (1400), being received by Philip of Burgundy, at whose desire Christine wrote *Le Livre des faitz et bonnes moeurs du sayge roy Charles* (1405), valuable as a first-hand picture of Charles V. and his court. Her *Mutation de fortune*, in which she finds room for a great deal of history and philosophy, was presented to the same patron on New Year's Day, 1404. It possesses an introduction of great autobiographical interest. In *La Vision* (1405) she tells her own history, by way of defence against those who objected to her pretensions as a moralist. Henry IV. of England desired her to make his court her home, and she received a like invitation from Galeazzo Visconti, tyrant of Milan. She preferred, however, to remain in France, where she enjoyed the favour of Charles VI., the dukes of Berry and Burgundy, the duchess of Bourbon and others.

Christine was a champion of her own sex. In her *Dit de la rose* (1402) she describes an order of the rose, the members of which bind themselves by vow to defend the honour of women. Her *Épître au dieu d'amour* (1399) is a defence of women against the satire of Jean de Meung, and initiated a prolonged dispute with two great scholars of her time, Jean de Montreuil (d. 1415) and Gonthier Col, who undertook the defence of the *Roman de la rose*. Christine wrote about 1407 two books for women, *La Cité des dames* and *Le Livre des trois vertus*, or *Le Trésor de la cité des dames*. She was devoted to her adopted country. During the civil war she wrote a *Lamentation* (1410) and a *Livre de la paix* (1412–1413), but after the disasters of the campaign of Agincourt she retired to a convent. We have no more of her work until 1429, when she broke her silence to write a song in honour of Joan of Arc. Of the circumstances of her death nothing is known but it probably took place about this time.

Her poems were edited by Maurice Roy for the Société des anciens Textes français (1886, etc.), and her *Livre du chemin du long estude*, by Puschel (Berlin, 1887). There are monographs by Raimond Thomassy (Paris, 1838); E. M. D. Robineau (Saint-Omer, 1882); and Friedrich Koch (Goslar, 1885). It is possible that Jean Castel, who was chronicler of France under Louis XI., was Christine's grandson. Hoccleve imitated her *Épître au dieu d'amour*, in his "Letter of Cupid" (*Chaucerian and other Pieces*, ed. W. W. Skeat, 1897). A translation of her *Épître d'Othéa* was made (*c.* 1440) by Stephen Scrope for his stepfather, Sir John Fastolf, and is preserved in a MS. at Longleat. This was edited (1904) for the Roxburghe Club by W. G. F. Warner as *The Epistle of Othea to Hector, or the Boke of Knyghthode. The Moral Proverbs of Christyne de Pise*, translated by Earl Rivers, was printed in 1478 by Caxton, who himself translated, by order of Henry VII., her *Livre des faitz d'armes, et de chevalerie*, a treatise on the art of war, based chiefly on Vegetius. Her *Cité des dames* was translated by Brian Anslay (London, 1521).

PISANO, ANDREA (*c.* 1270–1348), Italian sculptor, was born about 1270, and first learned the trade of a goldsmith. His style was influenced to some extent by Giovanni Pisano. His chief works were executed at Florence, and the formation of his mature style was due rather to Giotto than to his earlier masters. Of the three world-famed bronze doors of the Florentine baptistery, the earliest one—that on the south side—was the work of Andrea; he spent many years on it; and it was finally set up in 1336[1]. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues, and the rest scenes from the life of the Baptist. At the death of Giotto in 1337, Andrea was appointed architect of the campanile, and built the two stories of niches above the work of Giotto. Of the beautiful panel-reliefs which decorate the campanile those representing "The Crane," "Weaving," "Daedalus," "Navigation," "Hercules," "Agriculture," "Theatre" and "Medicine," display the style of Andrea Pisano. The duomo contains the chief of Andrea's other Florentine works in marble. In 1347 he was appointed architect in the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The date of his death must have been shortly before 1349.

See M. Reymond, *La Sculpture Florentine* (Florence, 1897).

PISANO, GIOVANNI (*c.* 1249–after 1314), Italian architect and sculptor, was the son of Niccola Pisano. He developed and extended into other parts of Italy the renaissance of sculpture initiated by his father. He spent the first part of his life as a pupil and fellow worker of Niccola and appears as his collaborator at the fountain of the great piazza at Perugia. Between 1278 and 1283 he was employed on the cloister, which surrounds the Campo Santo at Pisa. In 1284 Giovanni was appointed "capo maestro" of the new cathedral at Siena. He began the magni-

[1] The date on the door, 1330, refers to the original wax model.

ficent façade. His design, however, was modified by the architects who succeeded him. From 1298 to 1301 he was employed on the pulpit of San Andrea at Pistoia. Then followed the pulpit of the cathedral at Pisa, completed in 1311. It was taken to pieces some two hundred years later, but fragments are to be seen at Pisa, and in the Berlin museum. The figures for the tomb of the Empress Margaret, now in the Palazzo Bianco at Genoa, were executed soon after the Empress' death in 1311. A number of statues of "The Virgin and Child" have been attributed to him on stylistic evidence. Among these the three most important are at Prato; in the Campo Santo, Pisa; and in the Arena chapel at Padua. The Cathedral of Pisa has a fine figure of the Madonna carved in ivory. Giovanni's early work was inspired by his father Niccola. Later his figures and draperies displayed the expressive flow of lines appertaining to the Gothic style. Like the work of most stonemasons in mediaeval times, his sculpture forms part of an architectural design. The subject matter of his carving was dictated by the liturgy of the church, and his interpretations are imbued with deep religious feeling.

PISANO, NICCOLA (*c.* 1225–*c.* 1278), Italian sculptor and architect settled at Pisa. A document among the archives of the Sienese Cathedral calls him son of "Petrus de Apulia," and most modern writers believe that he not only was a native of the province of Apulia in southern Italy, but also that he gained there his early instruction in the arts of sculpture and architecture. Except through his works, little is known of the history of Niccola's life. In 1259 as an incised inscription records, he finished the marble pulpit for the Pisan baptistery; this is his most important early work, and is entirely classical in spirit.

It is a high sexagon, on semicircular arches, with trefoil cusps, supported by seven marble columns, three of which rest on white marble lions. In design it presents a combination of Gothic forms with classical details. Five of the sides of the main sexagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Crucifixion and the Last Judgment. These are all works of the highest beauty, and a wonderful advance on anything of the sort that had been produced by Niccola's predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity; and the stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccola's study of the antique is most apparent. The veiled and diademed figure of the Virgin Mother, seated on a throne, recalls the Roman Juno; the head of Joseph behind her might be that of Vulcan; while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing and kneeling figures of the Magi.

The beautiful relief of the Deposition from the Cross in the tympanum over a side door at San Martino at Lucca was probably Niccola's most important work. Then followed the Arca di San Domenico, in the church at Bologna consecrated to that saint. This work was completed in 1267 in collaboration with the Domenican Fra Guglielmo. The most magnificent of Niccola's works is the great pulpit in Siena cathedral. It is much larger than that at Pisa, being an octagon on cusped arches and columns. The contract for this work (1266) discloses the names of Niccola's assistants:—Arnolfo (di Cambio) Donato, and Lapo—besides his son Giovanni. In the reliefs of this pulpit can be traced the influence of the great Gothic sculptors of France. They mark the beginning of a new epoch in the history of Italian sculpture; classical repose is sacrificed for expression of religious emotions.

Niccola's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of three basins rising one above another, each with sculptured decoration; it was begun in 1274 and completed, with the co-operation of Niccola's son Giovanni, and of Arnolfo di Cambio. Niccola appears also to have had knowledge of architecture, for, when he signed the contract for the pulpit in Siena, he stipulated that he might go to Pisa four times a year to attend consultations about the building of the cathedral and baptistery. Many important buildings are ascribed to him by Vasari without corroboration. In 1278 Niccola is mentioned for the last time as working on the fountain in Perugia. The first record of his death occurs in Sienese archives under the date Aug. 30, 1287.

See SCULPTURE, and general histories of Italian art; Symonds, *Renaissance in Italy;* K. Frey, Vasari I. (1911, 1909, p. 423); I. Supino, *Arte Pisana* (Florence 1904); M. Reymond, *La sculpture florentine I* (Florence, 1897); A. Brach, *Nicola and Giovanni Pisano* (Strassburg 1904).

PISANO, VITTORE (1397–1455), commonly called PISANELLO, Italian medallist and painter, was the son of a Pisan father called Bartolommeo and a Veronese mother. He was one of the leading artists of his age, and enjoyed great celebrity during his lifetime. Guarino, a distinguished humanist, sings his praises in lines such as these: "Great is the renown that comes to Verona from the excellence of your work," and "Our age has produced you to be numbered with the great sculptors and painters of antiquity." We know nothing concerning Pisanello's artistic education. Vasari, who likes to derive all great art from Florence, states that he studied under Andrea del Castagno in Florence. But he was more probably trained in Verona in the traditions of Altichiero. About 1422 he worked in conjunction with Gentile Fabriano in the great council hall of the doge's palace in Venice. During their stay in Venice the two artists exercised a great influence on the development of Venetian art. Pisanello was much favoured by the princes and potentates of Italy. There is evidence that he worked at various times at Ferrara, Mantua, Milan, Pavia, Naples, Rome, Venice and Verona. He was well received at the courts of his patrons; he designed their costumes, the patterns of the material they used, the harness for their horses, besides painting their portraits and Madonna pictures.

Unfortunately, only very few of his paintings have survived. These are: the fresco of "The Annunciation" in S. Fermo at Verona and the fresco painted on the arch of the Pellegrini chapel in S. Anastasia, in the same city, representing "St. George Mounting his Horse"; three easel pictures may be singled out as representative of the master; the "Miraculous Stag appearing to St. Eustace" in the National Gallery, London; the portrait of a princess of the house of Este in the Louvre; and the portrait at the gallery in Bergamo of Lionello d'Este, who was one of the artist's chief patrons and admirers. These panels are carefully finished to the minutest detail, and are beautifully drawn. The Louvre possesses in the Vallardi book a number of delicate and spirited pen drawings by Pisanello. These detailed studies of nature, in which animals figure very largely, seem to have been his great delight and display the powers of an extraordinary draughtsman. But it is for his medals and plaques that Pisanello is best known. Although he was not, as was at one time asserted, the inventor of the medal, it was he who initiated this form of art as one of the most characteristic productions of the Renaissance. Pisanello's earliest medal was probably that of the Greek emperor John VII. Paleologos, dated about 1438–39.

See Aloiss Heiss, *Les Médailleurs de la Renaissance* (1881); G. F. Hill, *Pisanello* (1905); J. de Foville, *Pisanello et les Médailleurs Italiens* (1908); G. Biadego, *Pisanus Pictor* (Venice, 1908); *Les Dessins de Pisanello et de son École conservés au Louvre* (1911–20). (I. A. R.)

PISAURUM (mod. Pesaro, *q.v.*), an ancient town of Umbria on the Via Flaminia, 26 m. from Ariminum and 8 from Fanum Fortunae. A Roman colony was founded here in 184 B.C., at the mouth of the river Pisaurus (mod. Foglia; the sea has since receded about half a mile). It was destroyed by the Goths in 539, and restored by Belisarius in 545.

PISCES, the "Fishes," in astronomy, the twelfth sign of the zodiac, represented by two fishes tied together by their tails, and denoted by the symbol ♓. In Greek legend Aphrodite and Eros, while on the banks of the Euphrates, were surprised by Typhon, and sought safety by jumping into the water, where they were changed into two fishes. This fable, however, as in many other similar cases, is probably nothing more than an adaptation of an older Egyptian tale. The constellation contains only faint stars

without any striking grouping.

Piscis australis or *Austrinus,* the southern fish, is a constellation of the southern hemisphere. It contains Fomalhaut, a star of the first magnitude.

Piscis volans, the flying fish, is a constellation introduced by John Bayer in 1603. The name is now abbreviated to *Volans.*

PISCICULTURE. The species of food-fish that can be kept successfully in ponds throughout their lives from egg to adult are exceedingly limited in number. The various breeds of gold fish and top-minnows (*Cyprinodonts*) are familiar examples and the carp is an example of food-fishes capable of similar domestication. In the United States the eastern brook trout and the black bass are almost as fully domesticated. Various other food-fishes, both marine and fresh-water, can be kept in ponds for longer or shorter periods, but refuse to breed, while in other cases the fry obtained from captive breeders will not develop. Consequently there are two main types of pisciculture: (1) the rearing in confinement to an edible stage of the young of domesticated breeders; (2) the stocking of natural waters with eggs or fry from captured adults.

Fish-rearing.—Of the first type of pisciculture there are several examples of commercial importance in the cultivation of fresh-water fishes. The pond culture of carp is important in China and Germany, but in England it has long fallen out of use and is not likely to be resumed so long as other fresh fish can be obtained and distributed so readily as is now the case. In the United States pond culture of carp has been practically discontinued because of the prejudice of native Americans against the fish and because of its great increase in natural waters which now afford a large commercial yield. In Germany, on the other hand, intensive methods have been applied to pond culture with remarkable results in recent years.

In the United States some species of trout and charr have become so thoroughly domesticated that many commercial trout hatcheries have been established, some of them with a score of ponds heavily stocked with eastern brook trout (*Salvelinus fontinalis*) sorted into different ponds according to size and fed usually on slaughter house offal in addition to such natural food as they may obtain. Under this system the trout grow twice or three times as fast as the wild ones, a growth of from 7 to 11 in. during the first year being no exception. Some of the male fish are killed and sold before they are sexually mature; but most of the fish are kept until they reach sexual maturity in the second fall of their life at the age of 20 months and are then stripped and sold immediately thereafter.

Next in order of importance are the North American basses and sunfishes (family *Centrarchidae*), all of which make "nests." The most important members of the family are the largemouth (*Aplites salmoides*) and smallmouth (*Micropterus dolomieu*) black bass which are propagated in large numbers of State, national and private ponds. Artificial nest-boxes with bottoms covered with material suitable for the species are placed in the ponds, the fish spawn in them and the male guards the nests and schools of fry. The schools of young, usually numbering several thousand to the nest, are transferred to rearing ponds and fed on Japanese *Daphnia* raised in small separate ponds and on other food. Young bass are usually planted as fingerlings, 3 or 4 in. long or as yearlings. They could be raised for the market, but the cost would be prohibitive. In addition to the bass seven species of sunfishes are cultivated in the United States by similar, but simpler methods.

In the lagoons of the Adriatic and the salt marshes of various parts of France examples of the cultivation of salt-water fish are to be found analogous to the pond culture of fresh waters. Here, as in ancient Greece and Rome, it is the practice to admit young fish from the sea by sluices, into artificial enclosures or "viviers" and to keep them there until they are large enough to be used. An interesting modification of this method of cultivation has been introduced into Denmark. The entrances to the inner lagoons of the Limfjord are naturally blocked against the immigration of flatfish by dense growths of sea-grass (*Zostera*) although the outer lagoons are annually invaded by large numbers of small plaice from the North sea. The fishermen of the district consequently combined to defray the expenses of transplanting large numbers of small plaice from the outer waters to the inner lagoons, where they were found to thrive far better than in their natural habitat. The explanation has been shown by Dr. Petersen to be due to the abundance of food, coupled with the lack of overcrowding of the small fish. This transplantation of small plaice in Denmark has been annually repeated for many years with the most successful results and a suitable subvention to the cost is now an annual charge upon the Government funds.

As a result of the international North sea fishery investigations, it has been proposed to apply the same principle for the development of the deep-sea fishery in the neighbourhood of the Dogger Bank. Experiments with labelled plaice, carried out in 1904 by the Marine Biological Association, showed that small plaice transplanted to the Dogger Bank in spring grew three or four times as rapidly as those on the inshore grounds, and the same result, with insignificant variations, has been obtained by similar experiments in later years. (See *Reports* of the Ministry of Agriculture and Fisheries cited at the end.) In this case the deep water round the Dogger Bank acts as a barrier to the emigration of the small plaice from the shores. It has consequently been proposed that the small plaice should be transported in millions to the bank by well vessels every spring. It is claimed, as further result of the experiments, that from May to October the young fish would be practically free on the shallow part of the bank from the risk of premature capture by trawlers, and that the increased value of the fish, consequent upon their phenomenal growth rate, would greatly exceed the cost of transplantation. The development of seining on the Dogger Bank since 1919 has probably increased the risk of premature capture, but satisfactory information on this point is lacking. In the experiments made by the English Ministry of Fisheries the transplanted fish retaken by seiners amounted to about 20% of the total recaptured in 1922 and 1923, but the actual months are not stated.

Not unlike the work on plaice is the rescue work carried on in the United States, chiefly by the Bureau of Fisheries, but also by the States of Minnesota, Wisconsin, Iowa and Illinois. With the recession of the waters of the Mississippi river after spring freshets, many fishes become land-locked in temporary ponds or sloughs. By removing them to permanent waters they are saved from death due to drying of the ponds. In 1926 the Bureau of Fisheries seined about 150,000,000 impounded fish and returned them to open waters and similar work is undertaken each year.

In France and Japan the methods of oyster and mussel culture are similar in principle to those just described. A breeding stock is maintained to supply the ground or the "collectors" with spat, and the latter, when sufficiently grown, is then transplanted to the most favourable feeding grounds, care being taken to avoid the local overcrowding which is so commonly observed among shell-fish under natural conditions.

Fish-hatching.—The second and more familiar type of pisciculture is that known as fish-hatching, with which must be associated the various methods of artificial propagation. Fertilization of the spawn is easily effected by "stripping" the eggs from the female into a moistened pan and immediately adding the milt of the male by the same process (the dry or Russian method). Water is next repeatedly added and poured off to wash the milt from the eggs, which soon swell and harden so that they may be transferred to the hatching apparatus without injury. Although simple floating hatching boxes may often be used in natural waters, for large-scale operations hatcheries are constructed and the type of apparatus employed in them depends on the eggs to be hatched. For the smaller and lighter semi-buoyant or demersal eggs, such as those of whitefish (*Coregonus*), shad (*Alosa sapidissima*), etc., tall glass jars are used provided with a central inlet pipe through which water reaches the bottom of the jar and flows upward through the eggs to escape at the top. The dead eggs float and are removed by siphoning. The jars are grouped into "batteries," each of which may be merely a number of jars set on a table and supplied with water from a pipe above them, as in hatching shad. For hatching whitefish and pike-perch

eggs a battery may consist of more than 200 jars arranged in four superimposed tiers on two sides of a complicated system of wooden troughs, which serve to convey water to and from them.

For hatching the larger and heavier demersal eggs of trout and salmon primitive apparatus, still in use in parts of Europe, consists of long wooden troughs in which the eggs lie on gravel in running water. In more modern hatcheries, in order to economize space and utilize the water supply to the best advantage, the troughs are divided into "boxes" by transverse partitions and the boxes are filled with trays or baskets of eggs. The partitions are so constructed that the water which flows along the trough from box to box is given an upward or downward movement through the eggs in each box. For hatching trout eggs ten shallow wooden trays with bottoms of wire gauze each supporting a single layer of eggs are stacked in each box, covered by an empty tray and latched down by a cross-bar. A trough of five boxes carries from 500,000 to 750,000 eggs. The trout fry remain on the trays until a week or ten days before the yolk sac is absorbed and are then planted or transferred to rearing ponds. Four Pacific salmon baskets of wire screen are half filled with eggs (about 30,000), and one basket is placed in each box with the top projecting above the water so that no eggs can escape. The newly-hatched fry fall through the meshes in the bottom of the basket and remain on the bottom of the box until the heavy yolk is so far absorbed that they are able to swim upward. They may be then planted or held and fed in artificial ponds near the hatcheries to be planted when a year or more old.

For the buoyant eggs of cod, use is commonly made of the McDonald or tidal hatching box which is so constructed that a jet of water gives a rotary motion to the eggs while an intermittent siphon causes the water in the box to rise and fall at regular intervals, so that the rotating eggs are carried up and down much as they would be by the waves of the open sea.

The hatching of the eggs, whether of fresh or salt-water fishes presents no serious difficulties, if suitable apparatus is employed; but the rearing of fry to an advanced stage, without serious losses, is less easy, and in the case of sea-fishes, with pelagic eggs, the larvae of which are exceedingly small and tender, is still an unsolved problem, although recent work carried out at the Plymouth laboratory of the Marine Biological Association, in England, is at least promising. It has been found possible to grow pure cultures of various diatoms, and by feeding these to various larvae kept in sterilized sea water, great successes have been attained. In fresh-water culture there may be little advantage in artificial hatching, unless it is followed by a successful period of rearing. Thus the Howieton Fishery Company (England) recommended their customers to stock their streams either with unhatched ova sown in redds or with three-months-old fry. Their experience is "that there is no half-way house between ova sown in redds and three-months-old fry. Younger fry *may* do, but only when ova would do as well and at half the cost." In marine hatcheries, on the other hand, it is the invariable practice to hatch the eggs, although the fry have to be put into the sea at the most critical period of their lives, in an environment which teems with predacious enemies.

Some of the advances made in the United States in recent years in the cultivation of fish and shell-fish are shown by the examples which follow. They suggest the importance of a detailed knowledge of the life-history of the forms to be cultivated and the advantages of rearing to a suitable stage.

Decline in the Pacific salmon fishery led to the establishment of hatcheries until in 1921 there were 90 such establishments maintained by the United States, by the individual States, and by British Columbia. But in spite of the great hatchery output, the fishery continued to decline alarmingly in certain localities. This apparent failure of the hatcheries to rehabilitate the fisheries led the authorities of the United States and British Columbia to promote a co-operative and detailed study of the life history of the Pacific salmon in the hope that this would reveal better means of artificial propagation or enable fisheries restrictions to be intelligently applied, while in 1924, by act of Congress, full control of the Alaskan fisheries was placed in the hands of the Department of Commerce and has since been exercised by its Bureau of Fisheries.

There are five species of Pacific salmon (*Oncorynchus*) all of which ascend from the sea into the rivers to spawn and are captured in commercial nets on the upward journey. Unlike the Atlantic salmon, they invariably die after spawning, but the young hatched from their eggs return to the sea after a longer or shorter stay in fresh water. Investigations of the past ten years have added many important details of the life history. The method of investigation consists, in part, in marking the young by removal of some of the fins, releasing them in fresh water at various ages and in various places and recovering the marked fish when they return from the sea to fresh water to spawn. In part it consists of the microscopic study of the markings of the scales of returning adults. From these the age, rate of growth and period of time spent in fresh water may be determined. From these investigations it is now known that the fry may begin their return to the sea soon after hatching (pink and chum salmon), or may remain in fresh water for a year (silver salmon) or from one to four years (red salmon), or, as in the chinook, they may either start for the sea soon after hatching or when 12 or 18 months old. The age at return to fresh water also varies. In the pink it is invariably two years, in the chum from two to five or six years, in the silver three years, in the red three to seven years, in the chinook two to seven or eight years.

The salmon of each species almost invariably come back to spawn in the stream or lake in which they were hatched (parent stream). The most important discovery of recent years is this confirmation of the "parent stream theory" with the resultant conception of each species as made up of numerous self-contained colonies or races of interbreeding individuals. It results that if commercial fishing or other obstruction of a stream prevents so many individuals of any race from returning to their home spawning-ground that an adequate breeding stock is not maintained, that race is depleted or disappears and its racial ground is not afterward colonized by other races. It is then essential that commercial fishing be so conducted as to permit the escapement to the spawning ground of enough breeding fish of each colony to maintain that colony. In Alaska, the U.S. Bureau of Fisheries now requires a "spawning escapement" of 50%. This regulation was first imposed in 1924 and in 1926 the run of pink salmon, a two year fish, was the largest ever known. How large the spawning escapement must be to maintain a racial population in any locality is not yet definitely known. Actual counts made under the direction of Dr. Gilbert have shown that in the Karluk river, Alaska, three red salmon returned in 1926 for each parent fish of the 1921 spawning escapement. This ratio does not include the fish of the 1921 hatch that returned in earlier years or those still to return. If the proportion should prove to hold for all seasons an escapement of less than one-third would serve to maintain the race.

From studies made on the return of young salmon marked and released in fresh water, evidence is accumulating that artificial propagation may be made effective. It has been found that marked fingerlings of the Alaskan sockeye or red salmon, released in the Columbia river in the fall of their first year, fail to return, but if released in the spring of their second year, they return; success does not necessarily depend merely on the release of great numbers of large and vigorous fingerlings, but on their release at the right age, the age at which they naturally begin their seaward voyage. It has been found, further, that since each tributary (Columbia river) supports a separate colony it is inadvisable to transfer fingerlings from one tributary to another. Different racial groups start their spawning migrations at different times and each starts at such a time as to bring it to the spawning grounds when conditions there are suitable for laying of the eggs and development of the young of that race. If fingerlings are released on an alien ground they will return as adults to it, but they may then find the conditions on it unsuited to them at the time of their return. By releasing the fry or fingerlings of each race on its home ground and at the right age better results may be expected from hatchery operations than have been reached up

to this time. Thus in an experiment on the Columbia river the number of returning adults, recaptured after having been marked as fingerlings and released on their home ground when of suitable age, was 30 times that necessary to produce the eggs from which they came (Holmes). Increased runs of Pacific salmon are also reported by Canadian officials as the result of hatchery operations in the Frazer river.

In the United States many of the natural oyster beds have been so exploited that they have disappeared and others are greatly depleted. The great size of the beds, the high cost of labour and the relatively low price of the product make the method of pond culture current in France and Japan (*see* p. 936) impracticable. Culture consists at present wholly of rehabilitating the beds in natural waters and increasing their number (planted beds). About half the 30,000,000 bu. of oysters marketed annually are now obtained from planted beds and in the New England States about 90% are from that source.

It has long been known that fertilized eggs could be obtained by cutting open oysters and stripping the apparently ripe milt and eggs from them, but recently oysters have been induced to spawn naturally in tanks of sea water by permitting the temperature to rise to about 70° F and in this way better results have been obtained. But, for artificial culture, large numbers of the minute larval oysters must be raised to the fixed or spat stage. This has been hitherto impossible owing to the difficulty of retaining them in tanks while supplying them with running water. Until they are several days old they pass readily through felt or the finest silk bolting cloth. A new filtering material, known as "filtros" has now proved entirely satisfactory and several lots of larvae have been reared to the spat stage by investigators of the U.S. Bureau of Fisheries. Seed oysters for planting have become increasingly scarce and costly, but if the method referred to becomes a part of commercial oyster culture they may be produced in quantity at a cost much below that of collecting them from the beds.

In the United States the supply of the species of fresh water mussels from which pearl buttons are made has declined in recent years with the result that much work has been done on methods of cultivating these forms. The larvae (*glochidia*), after expulsion from the gills of the female mussel, become parasitic on the gills of fish from which they draw their nourishment and from which they fall after transforming into young mussels. In the earlier attempts to increase the mussel supply, fish artificially inoculated with glochidia were released into natural waters and not only fish captured for the purpose, but great numbers of rescued fish (*see* above) were used. In 1926 fish rescued and released by the U.S. Bureau of Fisheries had been inoculated with nearly 3,000,000,000 glochidia taken from about 40,000,000 mussels. Later experiments showed that the inoculated fish could be held in troughs until the young mussels dropped from them. The latter are then cared for during the first season of their growth. But the number of glochidia that can be safely carried by a single fish is limited, and the inflammation caused by over-infestation results in many deaths. Hence, a method was sought of rearing the glochidia without permitting their attachment to a fish host. Although the inoculation of both fish to be held captive and of those to be released is still practised, it recently has been found that the glochidia may be reared to young mussels in an artificial medium which supplies the nourishment normally drawn from the fish host and makes the use of the latter unnecessary. With perfection of the technique it is practically certain that young mussels will soon be raised and distributed in large numbers without employing fish hosts.

In the lobster (*Homarus*) the eggs are carried attached to the appendages of the lower surface of the abdomen of the female and average 30,000 in lobsters 13 in. long. The larvae hatched from the eggs pass through a remarkable series of transformations at successive moults. During the first four stages they are minute and free-swimming and subject to destruction by storms and countless enemies; but at the close of the fourth stage, or in the fifth, they become ambulatory, descend to the bottom and show an ability to protect themselves. "One lobster at this stage is worth many thousands in the first" (Herrick). Owing to the hard outer shell it is not possible to "strip" the lobster and cultivation, therefore, consists in rearing the naturally-hatched young through the helpless free-swimming stages to the ambulatory bottom stage capable of self protection. The most successful method is that devised by Mead and his co-workers and first used at Wickford, R.I., under the auspices of the Rhode Island commissioners of inland fisheries.

The unit apparatus is a wooden box 10 ft. square and 4 ft. deep with screened openings in the bottom and on two opposite sides near the top. The boxes, in groups of six, float with tops above water, supported by rafts 75 ft. long anchored in the sea in a protected situation where the water is of suitable quality. Near the bottom of each box a horizontal two-bladed propeller, with a radius of about 4½ ft., is made to revolve by means of suitable shafts and gearing driven by a naphtha motor or other power source. The propeller draws water through the screened opening in the bottom of the box and forces it upward in a spiral course to its escape through the side openings. Egg-bearing or "berried" lobsters are placed in one of the boxes just before the eggs are ready to hatch and, as hatching takes place, the fry are carried toward the top of the box and kept in suspension as though in the open sea. For rearing, the fry are transferred to other boxes where they secure natural food from the entering sea water but are also supplied abundantly with other food, preferably chopped, cooked beef, which is kept in suspension by the current and retained in the box by the screens. During the six to eight weeks season 500,000 "fourths" may be reared in 24 boxes. The method is believed to produce about 80 times as many fourths as are necessary to maintain the normal population of adults and heavy captures are therefore possible without depleting the grounds.

Objects and Utility of Fish-hatcheries.—The earlier advocates of artificial propagation and fish-hatching seem to haye been under the impression that the thousands of fry resulting from a single act of artificial propagation meant a corresponding increase in the numbers of edible fish when once they had been deposited in suitable waters; and also that artificial fertilization ensured a greater proportion of fertilized eggs than the natural process. For the first proposition there is no evidence, while the second proposition is now discredited. The advantage of artificial hatching lies in protecting the unhatched eggs from the very large destruction to which they are subjected under natural conditions. But it is recognized that the great fertility of fishes is nature's provision to meet a high mortality—greater in sea-fishes with minute pelagic eggs—a condition which entails a greater delicacy of their larvae at the time of hatching. Artificially propagated eggs and fry must submit, *after planting*, to the same mortality as the other eggs and fry around them. Consequently it is useless to plant out eggs or fry unless in numbers sufficiently great to increase appreciably the stock of eggs and fry of the same age already existing. It is this, combined always with the suitability of the external conditions, which accounts for the success of the best-known experiments of American pisciculturists.

The shad fisheries of the streams of the east coast of the United States declined on the whole 74% from 1896 to 1923, and are now totally destroyed in many streams, in spite of plants of fry which reached the large total of 400,000,000 in 1898, but owing to the difficulty of obtaining breeding fish, has since then in general, declined to about 35,000,000 in 1923. We have still little knowledge of the habits and life history of the shad, of the extent and direction of its migrations. Its ascent of streams has been often impeded by dams, and pollution has doubtless adversely affected the spawning migration, vitiated the breeding grounds and destroyed the fry. Artificial hatching has failed to maintain the species in Atlantic waters under these handicaps and in the face of intensive fishing. Under more normal physical conditions and with fuller knowledge of the life history of the species it might be effective in these waters as it begins to be in the case of the Pacific salmon. The artificially propagated eggs of the shad from the eastern rivers of the United States were planted in those of California, where the species did not naturally

occur. The conditions were suitable, and the species became at once acclimatized and has increased greatly. Similarly, reservoirs and streams can be stocked with various kinds of fish not previously present. But in the case of indigenous species the breeding stock must be very seriously reduced before the addition of the eggs or fry of a few score or hundreds of fish can appreciably increase it.

In the case of sea-fishes it is becoming increasingly recognized that the millions of cod fry which are annually turned out of the American, Newfoundland and Norwegian hatcheries are but an insignificant fraction of the billions of fry naturally produced. A single female cod liberates, according to its size, from one to five million eggs in a single season. Yet the annual output of fry from each of these hatcheries rarely exceeds 200,000,000, *i.e.*, the natural product of a few hundred cod at most. In Britain, marine hatcheries have been established by the Fishery Board for Scotland in the Bay of Nigg, near Aberdeen, by the Lancashire Sea Fisheries Committee at Peel, and by the Government of the Isle of Man at Port Erin. These establishments have been principally devoted to the hatching of the eggs of plaice. But again the maximum output of fry from any one of these establishments has not exceeded 50,000,000 in any single year. As a single female plaice produces about 200,000 eggs per annum, this output does not exceed the natural produce of a few hundred fish. Under these circumstances the probable utility of the operations could be admitted only if the fry were sedentary and could be planted in suitable localities where young fish were naturally scarce. But the fry drift with the currents as helplessly as the eggs, and the *a priori* objections to the utility of the operations have in no case been met by satisfactory evidence of tangible results.

The Scottish Fishery Board carried out a large scale experiment from 1896 to 1908 which was very illuminating (Fulton, 26th *Report*). They attempted to measure the density of young plaice on the beaches of Loch Fyne during six years when plaice fry were liberated in the loch and a similar period when none were added. From 1896 to 1901 the quantities of fry added were 4, 21, 19, 16, 30 and 51 millions annually, the number of eggs naturally present in the loch being estimated at nearly 500,000,000 in 1898 (Williamson, 17th *Report*). Although the figures of young plaice on the beaches yielded an average density which was twice as great in the first period as in the second (88:40 per hour), there was little or no correspondence from year to year between the density of young fish and the number of fry planted. The highest record corresponded with the year of maximum output of fry (1901), but the next highest occurred in 1905, when no fry were planted, and the third occurred in the first year (1896), when the number planted was negligible (4,000,000). Assuming (which is not certain) that the coincidence in 1901 was significant, it nevertheless appears that the natural fluctuations in the number of young plaice were unaffected by the hatching operations except in the one year when the number of fry liberated exceeded 50,000,000 and thus formed an appreciable proportion (10%) of the number estimated to be naturally present. Even these numbers do not provide Loch Fyne with a regular plaice fishery.

In the United States the utility of the cod-hatching operations has, in the past, been often asserted by representatives of the Bureau of Fisheries, but practically the only evidence adduced is the occasional appearance of unusual numbers of cod in the neighbourhood. It has not been established that the fluctuations in the local cod fisheries bear any relation to the extent of the hatching operations, while the earlier reports of the commissioner of fisheries contain evidence that similar fluctuations occurred before the hatching of "Fish Commission Cod" began.

The situation is much the same with regard to the operations of the Newfoundland hatcheries at Dildo. (*See* Fryer, *Reports* x.–xii. of H.M. inspectors of sea fisheries, E. and W.)

The most exact investigations bearing upon this problem are those undertaken in Norway in connection with the cod-hatching operations at Arendal under Captain Dannevig. Four fjords were selected on the south coast of Norway in proximity to the hatchery, and the usual number of fry (10 to 30 millions) was planted in the spring in alternate fjords, leaving the intermediate fjords unsupplied. The relative number of young cod in the various fjords was then carefully investigated throughout the succeeding summer and autumn months. It was found that there was no relation between the abundance of young fish and the presence or absence of "artificial" fry. In 1904, 33,000,000 fry were planted in Sondelfjord and young fish were exceptionally abundant in the following autumn (three times as abundant as in 1903, when no fry were planted). But their abundance was equally striking in other fjords in which no fry had been planted, while in 1905 all the fjords were deficient in young cod whether they had been planted with fry from the hatchery or not. (For a summary of these investigations see *Papers* on "Artificial Fish-hatching in Norway" by Captain Dannevig; and Dahl, *Report* of the Lancashire Sea Fisheries laboratory for 1906, Liverpool, 1907.)

It would seem clear that the attempts hitherto made to increase the supply of sea-fish by artificial hatching alone have been unsuccessful. The experience gained has doubtless not been wasted, but the direction to be taken by future work is plain. The energy and money devoted to hatching operations should be diverted to discover a means of rearing on a large scale the just-hatched fry of the more sedentary species to a sturdy adolescence. When that has been done it will be possible to deposit the young fish in suitable localities, on a large scale, with a reasonable prospect of influencing the local abundance of the species of fish in question. The increase of the supply of the migratory marine species, such as the cod, depends on a more complete knowledge of habits, life histories and migrations. With this knowledge in hand these fisheries *may* be maintained or increased either through regulation or by artificial propagation or by both means; until it is in hand the effect of artificial propagation cannot be estimated.

In the smaller bodies of fresh water there is no doubt of the effectiveness of hatchery operations, but in the Great Lakes of North America there is no dependable evidence of their value. Official statistics studied by P. Reighard in 1908 showed, on their face, a correlation between the average intensity of the plants of whitefish fry in certain regions of the Great Lakes during three five-year periods from 1892 to 1906 and the average catch of whitefish for the same periods. Intensive planting was found to be correlated with an increased fishery output and was recommended. On the other hand Dr. Koelz, who has an intimate knowledge of the fisheries operations of the Great Lakes is doubtful of the value of statistics based largely on reports of interested parties, the fishermen. He points out further that the planted fry are a very small fraction of those presumably hatched naturally (0·35% in Lake Huron in 1900).

The decline in the coregonine fisheries of the Great Lakes is further evidence of the inadequacy of present hatchery methods Whether the whitefish (*Coregonus clupeaformis*) has declined is uncertain, but the bluefin of Lake Superior and the bloater of Lake Ontario (both forms of *Leucichthys nigripinnis*) have become commercially extinct and in 1925 the important Lake Erie herring (*L. artedi*) suddenly gave out and has not since regained its commercial importance. The bluefin and bloater were never propagated artificially, but hundreds of millions of Lake Erie herring eggs have been hatched annually. It appears from these three cases that, for some unknown reason, *when the breeding stock of a gregarious fresh-water species has been reduced below a certain numerical minimum the decrease continues.* In the case of the bloater it has led to extinction and the important Lake Erie herring, in spite of extensive hatchery operations, appears now to be faced with extinction. The value of artificial hatching as hitherto carried out in the Great Lakes is now questioned in the United States for the reasons stated above and in Canada the abolition of hatcheries has been advocated by Prof. Knight of the biological board of Canada. It is probable that the life histories and migrations of many species approach in intricacy those of the Pacific salmon with its numerous, independent, self-sustaining colonies or races. Until these intricacies are resolved by prolonged research and hatchery operations adjusted to them, it is felt that artificial propagation is, in most cases, carried on

blindly and that success depends on chance.

PISCINA, originally a fish pond; later any artificial pool or tank, such as a bathing or swimming pool. Ecclesiastically the term is used for the stone basin with a drain emptying upon virgin soil, in which the utensils of the mass are cleaned and ritual ablutions performed. In mediaeval churches, especially in England, piscinae are most frequently in the chancel, close to the altar and often set in recessed, arched niches of great beauty.

A PISCINA IN EXETER CATHEDRAL

PISEK, a town of Czechoslovakia, on the Otava, a tributary of the Vltava, in one of the cereal and cattle basins of south Bohemia and on a main line from Prague to Budějovice, Linz and Vienna. Pop. (1927), 16,306.

PISEMSKY, ALEXEY FEOFILACTOVICH (1820–1881), Russian novelist, was born on his father's estate in the province of Kostroma, on March 22, 1820, the son of a major who had risen from the ranks. From the gymnasium of Kostroma he passed through Moscow university, and spent over 20 years in the government service. His first novel, *Boyarstchina,* was forbidden by the censor. His principal novels are *Tyufyak* ("A Muff"), 1850; *Tysyacha Dush* ("A Thousand Souls"), 1862; and *Vzbalomuchenoe marye* ("A Troubled Sea"), giving a picture of the excited state of Russian society about the year 1862. His *Gorkaya sudbina* ("A Bitter Fate"), depicting the dark sides of the Russian peasantry, obtained for him the Ouvaroff prize. He died at Moscow on Feb. 2, 1881. Pisemsky was a realist, and took an objective view of the unrest among the intelligentsia, which made him very unpopular in Moscow literary society. His best work is his description of the life of the common people. He learnt to know them thoroughly when investigating conditions in the Russian interior.

PISHIN, a district of Baluchistan. It consists of a large plain surrounded on three sides by hills, which formerly belonged to Afghanistan but was ceded to the British by the treaty of Gandamak in 1879. This plain is the focus of routes leading from Sind and the Punjab frontier districts to Kandahar, and is intersected by the Sind-Pishin railway. For administrative purposes it is included in the district of Quetta-Pishin; pop. (1921) 137,082.

PISHPEK: *see* FRUNZE.

PISIDIA, the name given to a country in the south of Asia Minor, immediately north of Pamphylia, by which it was separated from the Mediterranean, while it was bounded on the north by Phrygia, on the east by Lycaonia, Isauria and Cilicia, and on the west and southwest by Lycia and a part of Phrygia. It was a rugged and mountainous district occupied by wild and lawless races of mountaineers. The Pisidians are not mentioned by Herodotus, either among the nations that were subdued by Croesus, or among those that furnished contingents to the army of Xerxes. They furnished a pretext to the younger Cyrus for levying the army with which he designed to subvert his brother's throne, while he pretended to put down the Pisidians who were continually harassing the neighbouring nations by their lawless forays (Xen. *Anab.* i. 1, 11, etc.). They assume a more prominent part in the history of Alexander the Great, to whose march through their country they opposed a determined resistance. In Strabo's time they had passed under the Roman dominion, though still governed by their own petty chiefs.

Notwithstanding its rugged and mountainous character, Pisidia contained in ancient times several considerable towns, the ruins of which exist. The most important are Termessus, near the frontier of Lycia, a strong fortress in a position of great natural strength, and commanding one of the principal passes into Pamphylia; Cremna, another mountain fortress, north of the preceding, impending over the valley of the Cestrus; Sagalassus, a little farther north, a large town in a strong position, the ruins of which are among the most remarkable in Asia Minor, and Antioch, known for distinction's sake as Antioch of Pisidia, and celebrated for the visit of St. Paul. This was situated in the extreme north-east of the district immediately on the frontier of Phrygia, between Lake Egerdir and the range of the Sultan Dagh and was reckoned in the Greek and earlier Roman period, *e.g.*, by Strabo, as a city of Phrygia.

We have no clue to the ethnic character and relations of the Pisidians, except that we learn from Strabo that they were distinct from the neighbouring Solymi, who were probably a Semitic race, but we find mention at an early period in these mountain districts of various other tribes, as the Cabali, Milyans, etc., of all which, as well as the neighbouring Isaurians and Lycaonians, the origin is wholly unknown, and in the absence of monuments of their languages must remain so.

PISO, the name of a distinguished Roman plebeian family of the Calpurnian gens which continued in existence till the end of the 2nd century A.D. Nearly fifty of its members were prominent in Roman history, but the following deserve mention.

1. LUCIUS CALPURNIUS PISO CAESONINUS, Roman statesman, was the father-in-law of Julius Caesar. In 58 B.C., when consul, he and his colleague Aulus Gabinius entered into a compact with P. Clodius, with the object of getting Cicero out of the way. Piso's reward was the province of Macedonia, which he administered from 57 to the beginning of 55, when he was recalled, perhaps in consequence of the violent attack made upon him by Cicero in the senate in his speech *De provinciis consularibus*. On his return Piso addressed the senate in his defence, and Cicero replied with the speech *In Pisonem*. Piso issued a pamphlet by way of rejoinder, and there the matter dropped, Cicero being afraid to bring the father-in-law of Caesar to trial. At the outbreak of the civil war Piso offered his services as mediator, but when Caesar marched upon Rome he left the city by way of protest. He did not, however, definitely declare for Pompey, but

remained neutral. After the murder of Caesar he insisted on the provisions of his will being carried out, and for a time opposed Antony. Subsequently he became one of his supporters, and is mentioned as taking part in an embassy to Antony's camp at Mutina.

2. LUCIUS CALPURNIUS PISO, surnamed *Frugi* (the worthy), Roman statesman and historian, was tribune in 149 B.C. He is known chiefly for his *lex Calpurnia repetundarum,* which started the system of establishing regular courts for the trial of particular offences in place of the old system of special tribunals being appointed for each case. As praetor (136) and consul (133) Piso fought against the slaves in Sicily.

See ANNALISTS; C. Cichorius in Pauly-Wissowa's *Realencyclopädie* (1897), vol. iii., pt. 1; H. Peter, *Historicorum romanorum reliquiae* (1870), vol. i.; Teuffel-Schwabe, *Hist. of Roman Lit.* (Eng. trans.), § 132, 4. On the lex Calpurnia, *Corpus inscr. latinarum,* i., No. 198, with Mommsen's commentary; A. H. J. Greenidge, *Hist. of Rome, 133–104* B.C. (1904).

3. GNAEUS CALPURNIUS PISO, Roman statesman, was consul in 7 B.C. and subsequently governor of Spain and proconsul of Africa. In A.D. 17 Tiberius appointed him governor of Syria, with secret instructions to thwart Germanicus, to whom the eastern provinces had been assigned. The indignation of the people at the death of Germanicus, and the suspicion that Piso had poisoned him, forced Tiberius to order an investigation. Piso committed suicide, though it was rumoured that Tiberius, fearing incriminating disclosures, had put him to death.

See H. Schiller, *Geschichte der römischen Kaiserzeit* (1883), vol. i.

PISSARRO, CAMILLE (1831–1903), French painter, was born at St. Thomas in the Danish Antilles, of Jewish parents of Spanish extraction. He went to Paris at the age of twenty, and, as a pupil of Corot, came into close touch with the Barbizon masters. Though at first he devoted himself to subjects of the kind associated with the name of Millet, his interest was entirely absorbed by the landscape, and not by the figures. He fell under the spell of the rising impressionist movement, and threw in his lot with Monet and his friends. Like Monet, he made sunlight, and the effect of sunlight on the objects of nature, the chief subjects of his paintings, whether in the country or on the Paris boulevards. About 1885 he took up the method of the pointillists, but after a few years of these experiments he returned to a broader manner. In the closing years of his life he produced some of his finest paintings, in which he set down with admirable truth the peculiar atmosphere and colour and teeming life of the boulevards, streets and bridges of Paris and Rouen. He died in Paris in 1903.

Pissarro is represented in the Caillebotte room at the Luxembourg, and in almost every collection of impressionist paintings. A number of his finest works are in the collection of M. Durand-Ruel in Paris.

PISTACHIO NUT, the fruit of *Pistacia vera* (family Anacardiaceae), a small tree which is a native of Syria and generally cultivated in the Mediterranean region. It has a delicious flavour and is much prized by the Greeks and other Eastern nations. It is not so large as a hazel nut, but is rather longer and much thinner, and the shell is covered with a somewhat wrinkled skin. The pistachio nut is the species named in Gen. xliii. 11 as forming part of the present which Joseph's brethren took with them from Canaan, and in Egypt it is still often placed along with sweetmeats and the like in presents of courtesy. The small nut of *Pistacia Lentiscus,* not larger than a cherry stone, also comes from Smyrna, Constantinople and Greece. *P. Lentiscus* is the mastic tree, a native of the Mediterranean region, forming a shrub or small tree with evergreen pinnately-compound leaves with a winged stalk. "Mastic" (from *masticare,* to chew) is an aromatic resinous exudation obtained by making incisions in the bark. It is chiefly produced in Asia Minor and is used by the Turks as a chewing gum. It is also used as a varnish for pictures. *P. Terebinthus,* the Cyprus turpentine tree, a native of southern Europe, Asia Minor and North Africa, yields Chian turpentine from incisions in the trunk.

PISTOIA or **PISTOJA,** a town and episcopal see of Tuscany, Italy, in the province of Florence, from which it is 21 m. N.W. by rail on the main line to Bologna, with a branch to Lucca. Pop. (1921) 40,712 (town); 70,517 (commune). It is situated on a slight eminence (210 ft.) near the Ombrone, one of the tributaries of the Arno, immediately below the Apennines. It is on the site of the Roman *Pistoriae,* near which in 62 B.C. Catiline was slain and his forces destroyed. Excavations in the Piazza del Duomo led to the discovery of a large private house (end of 1st century B.C.). During the middle ages Pistoia was the scene of constant conflicts between the Guelphs and Ghibellines; here the great struggle took place which resulted in the creation of the Bianchi and Neri factions (Dante, *Inferno,* xxiv. 121). In 1302–06 it was besieged and eventually taken by the armies of Florence and Lucca, and in 1325 it became subject to Castruccio of Lucca. In 1351 it was obliged to surrender to Florence, and thenceforth shared its fate.

The city is still surrounded by walls, dating from shortly after the siege of 1302–06; while two inner lines of streets represent two earlier and inner lines of wall. A number of skilful artists between 1287 and 1399, made the great silver altar and frontal of the cathedral now in a chapel on the south side. The cathedral (13th century) has a campanile (218 ft. high) porch and façade with small arcades in black and white marble in the Pisan style as in other churches of Pistoia. It contains many fine sculptures—the monument of Cino da Pistoia, lawyer and poet, Dante's contemporary (1337), by Cellino di Nese, surrounded by his scholars, and Verrocchio's monument to Cardinal Forteguerra (1474). The octagonal baptistery is by Cellino (*c.* 1337). Among the earlier churches the principal is Sant' Andrea (1166), enriched with sculpture; in the nave is Giovanni Pisano's magnificent pulpit, imitated from his father's pulpit at Pisa. Other churches are S. Giovanni Fuorcivitas (so called because it was outside the line of the earliest, pentagonal, enceinte of the middle ages), with one of the long sides elaborately adorned with small arcades in the Pisan style, in black and white marble, also with sculpture by Gruamons (1162) on the façade. Within are a beautiful group of the Visitation by Andrea della Robbia, and a fine pulpit by Fra Guglielmo of Pisa (1270). S. Bartolomeo in Pantano and S. Pietro Maggiore closely resemble it. San Francesco al Prato is a fine church of the end of the 13th century with interesting frescoes of the school of Giotto. San Domenico, a noble church, begun in 1294, contains the beautiful tomb of Filippo Lazari by Bernardo and Antonio Rossellino (1462–67) and other works of art. The Madonna dell' Umiltà (1494–1567) and S. Maria delle Grazie have fine Renaissance interiors, by the local architect Ventura Vitoni. The Palazzo del Comune and the Palazzo Pretorio, once the residence of the podestà, are both fine specimens of 14th-century architecture. The Ospedale del Ceppo has remarkable reliefs in enamelled and coloured terra-cotta on its exterior. Besides various medallions, there is a frieze of figures in high relief along the whole front—groups representing the Seven Works of Mercy—executed by Andrea Della Robbia between 1514 and 1525.

The word "pistol" is derived (apparently through *pistolese,* a dagger—dagger and pistol being both small arms) from Pistoia, where that weapon was largely manufactured in the middle ages.

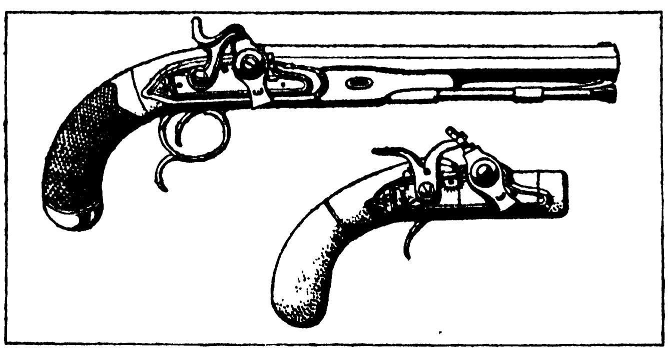
PISTOIA, SYNOD OF, a diocesan synod held in 1786 under the presidency of Scipione de' Ricci (1741–1810), bishop of Pistoia, and the patronage of Leopold, grand-duke of Tuscany, with a view to preparing the ground for a national council and a reform of the Tuscan Church. The synod was attended by 233 beneficed secular and 13 regular priests, and decided with practical unanimity on a series of decrees which, had it been possible to carry them into effect, would have involved a drastic reform of the Church on the lines advocated by "Febronius" (*see* FEBRONIANISM). The decrees were issued with a pastoral letter of Bishop de' Ricci (*see* SACRED HEART), and were warmly approved by the grand-duke, at whose instance a national synod of the Tuscan bishops met at Florence on the 23rd of April 1787. The temper of this assembly was, however, wholly different. The bishops refused to allow a voice to any not of their own order, and in the end the decrees of Pistoia were supported by a minority of only three. They were finally condemned at Rome by the bull *Auctorem fidei* of the 28th of August 1794.

Bibliography.—De' Ricci's own memoirs, *Memorie di Scipione de' Ricci, vescovo di Prato e Pistoia*, edited by Antonio Galli, were published at Florence in 2 vols. in 1865. Besides this his letters to Antonio Marini were published by Cesare Guasti at Prato in 1857; these were promptly put on the Index. *See* also De Potter, *Vie de Scipion de' Ricci* (3 vols., Brussels, 1825), based on a ms. life and a ms. account of the synod placed on the Index in 1823. There are many documents in Zobi, *Storia civile della Toscana*, vols. ii. and iii. (Florence, 1856). The acts of the synod of Pistoia were published in Italian and Latin at Pavia in 1788.

PISTOL, a small fire-arm designed for quick work and personal protection at close quarters, and for use in one hand. It was originally made as a single- and also double-barrelled smooth bore muzzle-loader, involving no departure in principle from the ordinary fire-arms of the day. With the introduction of revolvers and breech-loading pistols and the application of "rifling" to musket barrels, came also, in the early half of the 19th century, the rifling of pistol-barrels.

HISTORY

Pistols are understood to have been made for the first time at Pistoia in Italy, whence they receive their name. Caminelleo Vitelli, who flourished in 1540, is the accredited inventor. The first pistols, in the 16th century, had short single barrels and heavy butts, nearly at right angles to the barrel. Shortly afterwards the pattern changed, the butts being lengthened out almost in a line with the barrels. These early pistols were usually fitted with the wheel-lock (*see* Gun). Short, heavy pistols, called "daggs," were in common use about the middle of the 17th century, with butts of ivory, bone, hard wood or metal. A chiselled Italian dagg of 1650, for example, had a slightly bell-nosed barrel of about 8in. in length and 14 bore. The German wheel-lock military pistols used by the Reiters, and those made for nobles and gentlemen, were profusely and beautifully ornamented. Pistols with metal hafts were common in the 16th and 17th centuries, many beautiful specimens of which, silver-mounted, were made in Edinburgh and used by Highlanders. Duelling, when in vogue, caused the production of specially accurate and well-made single-barrelled pistols, reliable at twenty paces. The pattern of this pistol seldom varied, its accuracy at short range equalling that of more modern ones, the principle of a heavy bullet and light charge of powder being employed. The first double-barrelled pistols were very bulky weapons made with the barrels laid alongside one another, necessitating two locks and two hammers. There was also the "over and under" pistol, one barrel being laid over the other. This was a more portable weapon, only requiring one lock and hammer, the second barrel being turned round by hand, after the first had been fired, or,



FORSYTH LOCK PISTOL AND MODEL PREPARED FOR SUBMISSION TO THE BRITISH HOUSE OF COMMONS IN 1840

as an alternative, the flash-hole being adjusted to the second barrel by a key. These pistols were first made with flint and steel locks and subsequently for percussion caps. Double "over and under" pistols were also made with a trigger mechanism that served to discharge both barrels in turn.

Revolvers.—A revolver is a single-barrelled pistol with a revolving breech containing several chambers for the cartridges, thus enabling successive shots to be rapidly fired from the same weapon without reloading. The ordinary pistol has long been superseded by the revolver. The first revolver, fired with the percussion cap, was made with the whole of the barrels, six, seven or eight, revolving in one piece, and was known as the "pepper-box." It was "single action," *i.e.* the hammer was raised and the barrels revolved by the pull of the trigger. This weapon was cumbrous and no accurate aim could be taken with it owing chiefly to the strength and resistance of the main-spring and the consequent strong pull required on the trigger. The principle of a revolving breech to one barrel, which superseded the "pepper-box," is an old one in the history of fire-arms, dating from the 16th century. At first the breech cylinder was revolved by hand, as in the revolving arquebus or matchlock, a specimen of which is now in the Tower of London, but this was subsequently improved by introducing geared mechanism, by which the pull of the trigger or the cocking of the hammer, or both, do the work. There exists a pistol of the time of Charles I. which is rotated automatically as the hammer is raised.

In 1814 a self-acting revolver mechanism of a crude pattern was produced in England. Four years later Collier used a separate spring to rotate the chamber. In 1835, an American, Samuel Colt, produced and patented the first practical revolving pistol, the idea of which was obtained by him, it is stated, from an ancient "revolving" weapon in the Tower of London. The chambers of the first Colt revolver were loaded with powder and bullets from the muzzle end, and each chamber had a nipple that required to be capped. It was the invention of the copper cap that made the Colt revolver possible. Under the old priming system with exposed powder in a pan the difficulty of separate and effective ignition with the revolving cylinder was almost insuperable.

The first American revolver makers caused the cocking of the hammer to revolve the cylinder, while the English makers effected this by the pull of the trigger. In 1855, Adams of London, and also Tranter of Birmingham, brought out the double-action revolver, in which the revolution of the cylinder could be effected by both these methods. When the revolver is cocked and fired by pressing the trigger, greater rapidity of fire is obtained than when the hammer is cocked with the thumb, but accuracy is impaired, as the trigger requires a long pull and considerable force in order to compress the mainspring and revolve the cylinder. The double action revolver was, therefore, a great advance on the single action, enabling the first and also following shots, if desired, to be accurately fired by a moderate pressure of the trigger after the hammer had been cocked by the thumb; or, alternatively, the revolver could be rapidly fired, if necessary, by the trigger action alone. Many revolvers on the Colt principle were in use during the Crimean War and the Indian Mutiny, and proved of valuable service to British officers.

As rim-fire, pin-fire and central-fire cartridges were successively introduced, breech-loading revolvers were constructed to use them. Messrs. Smith & Wesson, of Springfield, U.S.A., produced the first metal cartridges for revolvers. Pin-fire cartridges, paper and metallic, were used on the continent of Europe for Lefaucheux and other revolvers, and these and rim-fire cartridges are still used for revolvers of small calibre. But since the central-fire cartridge has proved its superiority for guns, its principle has been generally applied to pistol cartridges.

The alteration of the muzzle-loading to the breech-loading chamber in the revolver involved no decided change of type. The original Colt, as a breech-loader, remained practically the same weapon as before, with a changed chamber. A hinged flap uncovered the breech-chamber on the right, and as each chamber reached that point the empty cartridge case was ejected by means of an ejecting-rod carried in a tube attached to the under side of the barrel and kept in place by a spiral spring, and the chamber reloaded. The next improvement was greater ease and rapidity of extraction, obtained first by Thomas's invention of making the barrel and chamber slide forward on the frame of the pistol. The extractor, being fast to the pivot, retained the cartridges until the chamber was pushed clear of them. Then the chamber was made to swing on one side, as in the Colt pistol of that time, enabling all the cartridges to be simultaneously extracted. Finally, self-extracting revolvers with jointed frames

were introduced, in which the dropping of the barrel forces out the extractor as in an ordinary double gun, the extractor acting simultaneously in all the chambers of the pistol. A spring returns the extractor to its place when the empty cartridge cases have been ejected. These are now known as "break-down" actions.

This type of revolver originated with Smith and Wesson, but they and other gun makers greatly improved on the original model. Between this American pattern and the English, as made by Webley, the chief difference is that in the Smith and Wesson, model 1888, the holding-down bolt or catch was upon the barrel, and it engaged with the top of the standing breech; whereas in the Webley the bolt was upon the standing breech and gripped the extremity of the hinged barrel. In the ·45, 1902 model, used by the British in the World War, this catch was eliminated. The frame was solid and the cylinder made to swing out to the left for the purpose of extracting, ejecting and recharging. The hinged type of revolver is most convenient for use on horseback, as the pistol can be opened, the cartridges extracted and the weapon reloaded with one hand.

Automatic Pistols.—After it had been shown that automatic machine guns could be made which would fire, extract and eject the empty round, and also load the next round into the chamber, application of this principle to pistols was attempted, and the first automatic pistol to appear was the Borchardt in 1893. This was not very certain in its action and was soon displaced in favour by the Mauser 7·65mm., 1898 model. This latter was provided with a wooden holster which could be attached to form a stock or butt. Later the bore was increased to 9mm., and in this pistol a more powerful cartridge was used, giving to its nickel-jacketed bullet a high velocity. This latter weapon, provided with a holster and sighted up to 1,000 yards, was used occasionally by the Boers during the last Boer War. Thus, it may be said, the vogue was started, and great development on these lines took place both in Europe and America. (X.)

MODERN REVOLVERS

Modern automatic pistols have many advantages over contemporary revolvers, and the armies of most nations are now armed with them with the exception of Britain, France, and at one time Russia. In the British navy the ·455 Webley Revolver is used.

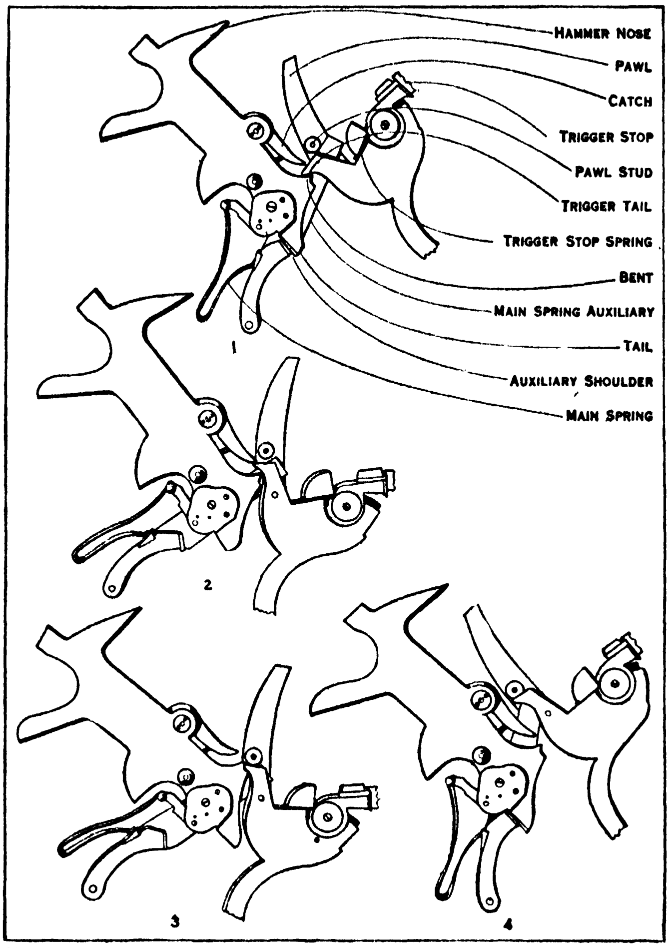
All revolvers are hand operated, but modern automatic pistols all rely for their operation on the effect of firing a round. The automatics are claimed to have the following advantages over revolvers—(a) Rapidity of fire, (b) rapidity of recharging (this is done by filled magazines), (c) each magazine holds more rounds, (d) flatter and more easily carried, and other minor points. Automatic implies continuous action in a machine gun, but it has not that meaning when applied to pistols, which, though called automatic are really semi-automatic in action, and require a separate pull of the trigger to fire each shot.

While admitting the advantages claimed for automatics, it is held that the revolver is:—(1) More certain, because, (a) it is positively manipulated by hand; (b) it is immune from questions of incorrect functioning due to variable recoil with slightly erratic ammunition; (c) being less complicated, it is more free from troubles due to mud and dirt or lack of lubrication. (2) A miss-fire is instantly corrected by pulling the trigger without moving the revolver or altering the aim. With the Automatic, the weapon has to be lowered, eyes removed from the enemy or target, and both hands used to overcome the stoppage that arises from the miss-fire, a difference perhaps of a few seconds of time that may be of vital importance. (3) Less liable to accidental discharge.

In ammunition used for automatic pistols the bullets have cupro-nickel envelopes, and they usually have a velocity rather more than medium. These envelopes help to facilitate the feeding of the round without friction or jamming in the magazine, and also when being forced from the magazine into the chamber. Were these bullets of unjacketed lead, they might not "take" the rifling in the barrel at the velocities employed, and hence the shooting would be inaccurate. Such jacketed bullets being much harder than lead have more penetrating power, and a great deal of their energy may be wasted, and expended in the further forward motion of the bullet after penetration.

The different makes of the modern revolver may be said to differ from each other in details only, and a description of the four main features of the revolver mechanism will be generally applicable to all. These four main features are, cocking and firing, cylinder rotation, rebound and safety.

Cocking and Firing.—All revolvers now are of the double action type, previously described, *i.e.*, cocking the hammer with the thumb; or, "pulling through" with the trigger when the hammer is forward. In both cases the hammer rotates about its axis, and in so doing compresses a spring, the mainspring, which is the driving force of the hammer (*see* diagram).



WEBLEY REVOLVER: (1) NORMAL FIRING POSITION. (2) SECOND FIRING POSITION SHOWING TRIGGER MECHANISM. (3) THIRD FIRING POSITION. (4) FOURTH FIRING POSITION

As the hammer is caused to rotate by the thumb in single action, its toe bears against and underneath the tail of the trigger, and this is caused to revolve about its axis until a point is reached when a bent in the toe of the hammer engages with the tail of the trigger. The mainspring, having been compressed, keeps the trigger in engagement with the bent of the hammer. If the trigger now be pulled, it will rotate still further until the tail of the trigger slips from the bent of the hammer when the hammer will fly forward to fire the round. In the "pull through" action, an accessory to the hammer comes into play, namely, the hammer catch. This, at its top end, rotates round an axis on the front of the hammer, while its bottom end is caused to protrude by a spring housed between the two and known as the hammer catch spring. When the trigger is pulled its tail, rotating upwards, engages with the bottom of the hammer catch, and so rotates it and the hammer in the opposite direction. Eventually a point is reached when the hammer catch and the trigger tail clearing each other, the hammer flies forward and fires the round.

Cylinder Rotation.—Another feature common to all revolvers is the means of rotating and positioning the cylinder of chambers. Around the central axis of the cylinder and protruding from its

rear face are the teeth of the ratchet, one tooth per chamber. To the inside of the tail of the trigger is pivoted the pawl. When the trigger is pulled the tail rises, bringing with it also the pawl. The top of the pawl bears against a tooth of the ratchet, so, when the pawl rises, it rotates the ratchet, and brings up the next chamber the full distance to place it in true alignment with the barrel (*see* diagram).

To prevent over-rotation of the cylinder, stops are provided which prevent movement beyond the exact amount necessary to ensure this alignment. Thus while these stops prevent over-rotation and the pawl prevents rebound, perfect alignment of the chamber and barrel is secured as is also that of the cartridge cap and hammer. These cylinder stops, pivoted to the trigger and influenced by a spring, protrude upwards through the bottom of the frame, and engage in slots on the outside circumference of the cylinder. They are so constructed as to disengage from these slots as the pressure on the trigger is released, and the latter starts to go forward. Were these stops to remain in their slots, the cylinder could not be rotated. (The Webley ·455 Revolver has two such stops, others usually have one.)

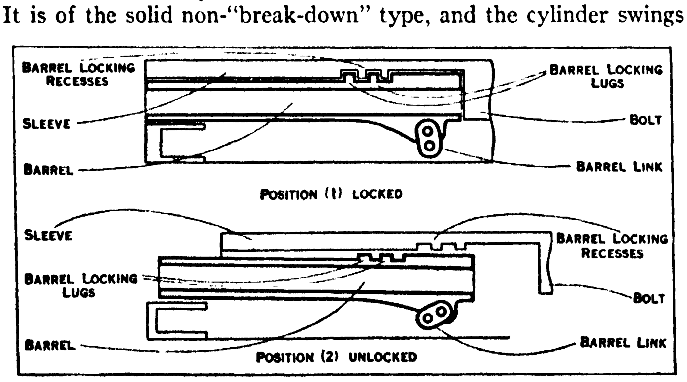
Rebound Action.—Furthermore, the cylinder could not be rotated were the hammer nose to remain in the indentation made in the cap of the cartridge case after being struck by the hammer. To meet this, rebound action is employed, *i.e.*, as the trigger starts to move forward after a shot has been fired, the hammer is caused to revolve slightly to the rear and thus clear its nose from the cartridge cap (*see* diagram).

In the Webley and Colt this action is effected by the lower arm of the mainspring pressing down on the mainspring auxiliary, a shoulder on which bears against the tail of the hammer so rotating it and returning it to its normal position.

Safety Action.—Accidental discharge through the hammer being knocked forward is also guarded against. In the Webley and Colt the tail of the hammer is shaped, so that if its top be pushed forward, its tail causes the auxiliary to rise. The front end of this bears against a stud on the pawl so raising it. It, in turn, raises the trigger, which meets the down-coming hammer catch, thus preventing further hammer movement. (*See* diagram.)

These last two actions are provided for in the Smith & Wesson by a block underneath the hammer. When the trigger is pulled this block is forced to the rear against a spring. As the trigger is released the block moves forward, a step on it meeting a step on the tail of the hammer, thus effecting the rebound action. As the trigger moves further forward, the block passes under the hammer tail and so prevents any forward movement by the top of the hammer.

The French army revolver is the 8mm. Modèle d'Ordonnance. It is of the solid non-"break-down" type, and the cylinder swings



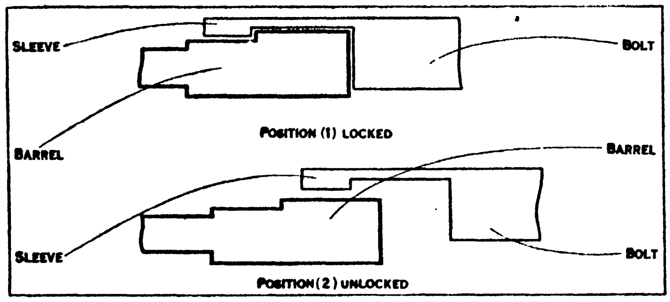
THE LOCK OF A COLT AUTOMATIC PISTOL

out to the right for ejection and loading. In the ·3 Russian Nagant, endeavours are made, both in the action and the ammunition, to bridge the space between the front of the cylinder and the breech of the barrel, through which gas escapes, a defect which is present in all other revolvers.

AUTOMATIC PISTOLS

Such weapons are now numerous and vary greatly in design, with calibres ranging from ·455 to ·250 inches. In all cases, however, their operation is depended on the result of firing a round. If the base of the cartridge be not supported in the chamber when it is exploded, it will be blown to the rear, the gas will escape, the bullet will not be projected, and the firer will also probably suffer.

Automatic Pistols can be divided into two main types, *i.e.*, (a) Those in which the barrel and bolt are positively locked to-



THE LOCK OF A WEBLEY & SCOTT AUTOMATIC PISTOL

gether till the bullet's exit. (b) Those dependent on inertia with no mechanical locking. The latter, for sealing the breech, rely on the weight of the moving parts which place the round in the chamber, and which hold it there by the assistance of strong springs, together with the friction on extraction caused by the cartridge case expanding under the explosion and gripping the walls of the chamber.[1]

The small bore pocket pistols are frequently of type (b). However, in view of the requirements of a revolver or pistol, previously referred to, type (a), which permit of a heavy bullet and a heavy charge, are usually the most employed for military purposes. There are two sub-divisions of type (a) namely, (1) Those in which the barrel and bolt recoil together in the same plane for a short distance prior to unlocking. (Luger Parabellum, Mauser [Germany], Frommer.) (2) A lowering movement of the barrel during recoil, which unlocks itself from the bolt after a short distance.[2] (Webley & Scott, Colt.)

The Luger functions on somewhat similar lines to the Maxim or Vickers Machine Gun. In it the bolt is supported by a toggle joint, the centre hinge of which is below the level of the ones on either side of it and bears against the metal of the frame. Locked in this way, barrel and bolt recoil together until the centre hinge meets a ramp and is forced upwards so breaking the joint and knuckling the bolt back against the compression of a spring.

Not quite similar to (1) and (2) above, is a third form of barrel movement, *i.e.*, a turning motion of the barrel during recoil, thus bringing about unlocking. (Steyr and Savage.)

Of type (b) a Browning 9mm. Military Model, manufactured in Belgium and marked F.N. (Fabrique National) is the weapon of Belgium, Holland and of some S. American States.

Owing to the similarity in outward appearance between various automatic pistols, not much can be learnt from photographs. However, on this page are diagrammatical sketches of the principles employed in some of the locking actions mentioned above.

Magazines.—All these pistols have magazines holding from 7–10 rounds, in three of which the magazines can be loaded while assembled by means of chargers, namely, the Bayard (out of date), Mauser and the Steyr. Safety catches are usually of two types, namely, thumb levers and grip levers. The former when applied, disconnect the hammer from the sear, so that pulling the trigger has no effect. The grip levers are at the back of the stock, and when not gripped by the hand as when firing, cause the hammer and sear to be disconnected with the same result as above.

Holding-open devices are embodied in most automatic pistols, and warn the user that the magazine is empty. The magazine platforms, or levers operated by them, rise when the maga-

[1]The cartridge cases of automatic pistols are always cylindrical. The greatest friction and therefore gripping of the chamber is produced by such cases when expanded.

[2]In this type the barrel and sleeve lock; the bolt, which is solid with the sleeve, seals the breech when this locking is effected.

zine is empty and hold back the recoiling parts, thus putting the pistol temporarily out of action.

A danger common to most automatic pistols is that when the magazine is removed a live round is usually left in the chamber, and, if forgotten, may result in an accident. Hammerless pistols give no indication as to whether the pistol is cocked or not. On the other hand, with hammers projecting at the rear of the pistol there is a possibility of cocking the hammer by an accidental knock or by friction.

There is only one well known sample of a semi-automatic revolver, namely, the Webley Fosbery ·45. In it is the usual six chambered cylinder. When the round is fired, the cylinder and barrel recoil and in so doing the cylinder is made to turn half the distance necessary for aligning of the next chamber with the hammer. After recoil a strong spring forces the recoiling portions forward and the cylinder rotates through the remaining necessary distance. (H. R. A.)

PISTOLE. The French name given to a Spanish gold coin in use from 1537; it was a double *escudo,* the gold unit, and was worth 16s. 11½d. sterling. The name was also given to the *louis d'or* of Louis XIII. of France, and to other European gold coins of about the value of the Spanish coin.

PISTON: *see* STEAM ENGINE; INTERNAL COMBUSTION ENGINES; PUMPS.

PITCAIRN, a borough of Allegheny county, Pennsylvania, U.S.A., 15 m. S.E. of Pittsburgh, on the Pennsylvania railroad. Pop. (1920), 5,738 (93% native white); 1928 local estimate, 7,000. The Pennsylvania company has railroad shops and freight yards here employing large numbers. Electrical goods, bricks and concrete blocks are manufactured in the borough, and there are coal mines in the vicinity. The borough was incorporated in 1894.

PITCAIRNE, ARCHIBALD (1652–1713), Scottish physician, was born at Edinburgh on Dec. 25, 1652. He took his M.A. degree at Edinburgh university in 1668, and after courses in Edinburgh and Paris he obtained in 1680 the degree of M.D. at Rheims. He began practice at Edinburgh, and in 1692 was appointed professor of medicine at Leyden. Among his pupils were Richard Mead and H. Boerhaave, and both of them attributed much of their skill to what they learned from Pitcairne. In 1693 Pitcairne settled once more in Edinburgh. He persuaded the Edinburgh town council to permit himself and certain of his medical friends to treat without fee the sick paupers in "Paul's Work," on condition of being allowed to dissect such of the bodies as were unclaimed by their relatives. In this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine. He died on Oct. 20, 1713.

PITCH. The name of various substances of dark colour and of extremely viscid and tenacious consistency when subjected to heat. (O. Eng. *pic,* an adaptation of Lat. *pix, picis,* Gr. πίσσα, πίττα, allied with Gr. πίτυς, pine-tree, Lat. *pinus.*) Strictly the term is applied to the resinous substance obtained as a solid residuum by the distillation of wood-tar (*see* TAR), or the non-resinous substance similarly produced from coal-tar (*q.v.*). The name is also applied to the natural mineral substances, *i.e.,* asphalt or bitumen (*qq.v.*).

PITCH, MUSICAL. The pitch of a musical sound is precisely defined by a vibration number recording the frequency of the pulsations of a tense string, a column of air or other vibrator, in a second of time. In Great Britain and America the complete vibration to and fro is taken as the unit; elsewhere the vibration in one direction only. The only official standard is the French, dating from 1859, preserved by a tuning-fork vibrating 870·9 (double vib. 435·45) at a temperature of 15° Centigrade (59° Fahr.) in a second. The vibration number stated in the edict establishing, in the year named, the diapason normal is 870 (435). Vibrations increase in rapidity as a note rises and decrease as it falls. Any note may be a pitch note. For orchestras custom has settled upon *a'* in the treble clef, for organs and pianos in Great Britain *c''*, and for modern brass instruments *b* flat'.

We are not without a clue to the pitch usual in the classic Greek and Alexandrian ages: the vocal octave to which the lyre was adapted was noted as from *e* to *e'*. As in choruses barytone and low tenor singers always prevail, *d–d'*, at French or at medium pitch, would really be the Greek singing octave; we may therefore regard it as a tone lower than that to which we are accustomed. But to sing the lower Greek modes in or near the vocal octave it was necessary to transpose (μεταβολή) a fourth upwards, which is effected in modern notation by a flat placed upon the B line of the staff; thus modulating from our major key of C to that of F. This transposition has had, as we shall see, much to do with the history of our subject, ultimately influencing the ecclesiastical chant and lasting until the 17th century of our era. It does not appear from any evidence that the keyboards—when there were more than one—of the early organs were arranged for transposition, but it is certain that the Flemish harpsichords to 1650 were made with double keyboards to accommodate it (*see* Hipkins's *History of the Pianoforte,* 1897). But a positive identity of pitch cannot be claimed for any period of time, and certainly not for the early organs; the foot-rule of the organ-builder, which had to do with the lengths of the pipes, and which varied in every country and province, could easily cause a difference of a semitone. Scale and wind-pressure are also important factors. But with all these often opposed conditions, we find less variation than might be expected, the main and really important divergence being due to the necessity of transposition, which added a very high pitch to the primarily convenient low one.

The first to attempt to define pitch would seem to have been Arnold Schlick (*Musica ausgeteutscht und ausgezogen,* Heidelberg, 1511), who gives a measure, a line of 4⅞ Rhenish inches, which, he says, multiplied sixteen times, should be the lowest F of a small organ. He gives no diameter or wind-pressure. Dr. A. J. Ellis used this indication to have an organ pipe made which with one-sixteenth diameter and a wind-pressure of 3¼in., at one-fourth Schlick's length, gave *f'* 301·6, from which he derived a just major third of *a'* 377, which would compare very well with an old Greek *a'*. Schlick goes on to say the organ is to be suited to the choir and properly tuned for singing, that the singer may not be forced to sing too high or too low and the organist have to play chromatics, which is not handy for every one. Further, he says pitch cannot be exactly defined, because voices vary; he nevertheless gives the measure above mentioned for the low F, but if a larger organ is built to include the still lower C, then this C must be *of the same measurement,* the reason being that a greater part of church music ends in "grambus," a word understood by Schlick's editor to mean the transposition of a fourth. The larger high-pitch organ will therefore be at *a'* 502·6.

The Halberstadt organ was, according to Praetorius, built in 1361, and repaired or rebuilt 1495. He gives the longest pipe of this organ, B natural, as 31 Brunswick feet, and the circumference 3½ft. He further tells us this pitch was a tone, nearly a tone and a half, higher than a suitable church pitch (*Chorton*), for which he gives a diagram. Dr. Ellis had pipes (now preserved in the Royal Institution, London) made to reproduce both these pitches at 3¼in. wind-pressure. The Halberstadt pitch was found to be *a'* 505·8; the *Chorton,* 424·2. Ellis used mean-tone temperament in calculating this lower pitch; but as he used just intonation for the Halberstadt, it seems preferable to substitute it for the *Chorton,* thus reducing it to *a'* 422·8. Praetorius's *Cammerton,* or chamber pitch, formulated in his diagrams for voices and instruments, is, he says, a whole tone higher; equivalent, therefore, to *a'* 475·65. Nearly all the German organs were tuned to this higher pitch. The lower vibration number is justified by the three divisions of the male voice, bass, tenor and alto, as given by Praetorius, whose *Cammerton* very closely corresponds with Bernhardt Schmidt's Durham organ, 1663–1668, the original pitch of which has been proved to have been *a'* 474·1. The Halberstadt pitch is nearly a semitone higher, which again agrees with the statement of Praetorius, and also Schlick's high C organ. Yet it would seem that there had been a still higher pitch used in the old ecclesiastical music. In one passage Praetorius distinctly says the old organ high pitch had been a whole tone above his *Cammerton,* with which we shall find his *tertia minore* combines to make the required interval. The term *tertia minore,* or *inferiore,* is used by Praetorius to describe

a low pitch, often preferred in England and the Netherlands, in Italy and in some parts of Germany. An organist, instead of transposing a whole tone down from the *Cammerton,* would for the *tertia minore* have to transpose a minor third.

Corroboration of this pitch is found in Silbermann's organ in Strasbourg minster (1713–1716), the pitch of which, taken in 1880 and reduced to 59° F (as are all pitches in this article), is *a′* 393·2. An old organ at Versailles (1789) was very near this example, *a′* 395·8. Ellis gave Dom Bédos (*L' Art du facture d'orgues,* Paris, 1766) as authority for a mean tone *a′* 376·6. Sir F. G. Ouseley's comparison of the church and chamber pitches of Orlando Gibbons (*vide* Ellis's lecture) clearly shows the minor third in Great Britain in the first half of the 17th century. But the narrowing continued. Bernhardt Schmidt, better known in England as Father Smith, was invited about 1660 to build the organ for the Chapel Royal, Whitehall; two years later he built the organ in Durham Cathedral *a′* 474·1, difference a whole tone, and practically agreeing with the *Cammerton* of Praetorius. The Hampton Court organ of 1690 shows that Schmidt had further lowered his pitch a semitone, to *a′* 441·7. What happened at Durham was that at some subsequent date the pipes were shifted up a semitone to bring the organ into conformity with this lower pitch, with which it is probable Schmidt's organs in St. Paul's and the Temple, and also Trinity college, Cambridge, agreed.

The final adoption of the low church pitch as in the 18th century was no doubt influenced by the introduction of the violin, which would not bear the high tension to which the lutes and viols had been strained. Harpsichords had long been preferred to the *tertia minore.* The *Chorton* of Praetorius, *a′* 422·8, is practically the same pitch as that of the fork the possession of which has been attributed to Handel, *a′* 422·5. It is a very fair mean between G. Silbermann's 18th-century Dresden pitch, *a′* 415, and the organs of Renatus Harris, *a′* 428·7. Stein tuned Mozart's piano to a fork *a′* 421·6, and the Broadwood pianos used at the first London Philharmonic Society concerts (1813) were tuned to a fork *c″* 506·8, which gives a mean tone *a′* 423·7.

According to Schindler (*Niederrheinische Musik-Zeitung,* 1855, Nos. 8 and 9) and the report of the French Commission, 1859, the rise in pitch began at the Congress of Vienna in 1816, the military bands being the cause. With the improvements in wind instruments this continued, as more brilliant effects were gained. In 1823 Weber's *Euryanthe* is recorded as having been played in Vienna at *a′* 437·5, and in 1834 Kreutzer's *Nachtlager* at *a′* 440. The measurements are doubtful, but the upward tendency is clear. Scheibler, by his simple and accurate tonometer, has recorded pitches in Vienna about 1834 from *a′* 433·9 to 440·2. About that time, or it may be a few years earlier, Sir George Smart established a fork for the Philharmonic Society, *a′* 433·2. Forks intended for this vibration number, stamped "Philharmonic," were sold as late as 1846. But about that year the performing pitch of the Society had reached 452·5. Sir Michael Costa was the conductor 1846–54, and from his acceptance of that high pitch the fork became known as Costa's, and its inception was attributed to him, though on insufficient grounds. In 1874 a further rise in the fork to *a′* 454 was instigated by Sir Charles Hallé. The British army is required by His Majesty's Rules and Regulations to play at the Philharmonic pitch, and a fork tuned to *a′* 452·5 in 1890 is preserved as the standard for the Military Training School at Kneller Hall. But the Philharmonic Society adopted the diapason normal in 1896, and the military bands have not gone with it.

It was the irrepressible upward tendency that caused the French Government in 1859, acting with the advice of Halévy, Meyerbeer, Auber, Ambroise Thomas and Rossini, to establish by law the diapason normal, *i.e., á* 439 at 68° Fahr. or *á* 435 at 59° Fahr. Other countries have gradually followed, and, with few exceptions, the low pitch derived from the diapason normal may be said to prevail throughout the musical world. Great Britain was the last to fall in, but the predominance of the low pitch is assured. The proprietors of Queen's Hall, London, did much for it when they undertook the alteration, at great expense, of their large concert organ, which had only just been erected. In 1896 the Philharmonic Society adopted the diapason normal and in 1899 Messrs. Broadwood made a successful effort to get the same vibration number accepted by their competitors in Great Britain. The high pitch remains only where there are large concert organs not yet lowered, and with the military and brass bands.

The consideration of temperature as affecting the use of a standard pitch was not attended to when the French Government issued its *ordonnance.* The 15° C attached to the description of the standard fork in Paris was intended for the definition and verification of the fork only. The alteration of the fork due to heat is scarcely perceptible, but wind instruments, and particularly the organ, rise almost proportionately to the increase in temperature of the surrounding air, because sound travels at an enhanced rate as the temperature rises. The coefficient of this rise is equivalent to half a vibration (0·5) per degree Fahr. per second. The French Commission, in establishing the diapason normal, should have chosen a temperature of 20° C. There would then have been less disturbance owing to the breath of the players and heat of the theatres or concert-rooms. As things are, even the established diapason normal implies a variation from 435 to 440 vibrations a second for *a′*, inasmuch as temperature must always be reckoned with.

In writings on music the pitch of a note is indicated in various ways when it is desired to convey this without the employment of actual notation. Thus organists speak of "great C," "double C" and "tenor C" to indicate the notes sounded by pipes of 16ft., 8ft. and 4ft. respectively, the same notes being also indicated alternatively by the lettering CCC, CC and C. Another system is based on the employment of different types (*i.e.,* either capitals or small italic letters), supplemented by small strokes, placed above or below the letters as the case may be. Thus under this system 16ft. C is represented by C′, 8ft. C by C without any stroke, 4ft. C by *c*, the C above ("middle C" on the pianoforte) by *c′*, the C above that (or treble C) by *c″*, the C above that again by *c‴*, and so on, the intermediate notes in each octave being of course similarly indicated. Or instead of strokes small numerals are sometimes used, *e.g.,* C_2, C_1, c^1, c^2, c^3, etc. The expressions "in alt" and "in altissimo" are also employed for the same purpose, "in alt" signifying the notes in the octave beginning with the C above the treble octave (*g″*) and "in altissimo" those in the octave above (*g‴*, *a‴*, *b‴*, etc.). (*See* ALT.) (A. J. H.; X.)

PITCHBLENDE or **URANINITE,** a mineral species consisting essentially of uranium oxide, of importance as a source of uranium and radium. It is a very heavy (specific gravity 9·0–9·7), compact mineral with a conchoidal to uneven fracture, and a brownish to velvet-black colour and pitchy lustre. Crystals are rare; they have the form of regular octahedra or less often of cubes. The hardness is 5½, and the streak is brown with a greenish tinge. The mineral has been known since 1727 to occur at Jáchymov (Joachimsthal) in Bohemia, and it was early called pitchblende because of its appearance; but its true nature was not recognized until 1789, when M. H. Klaproth's analysis of it resulted in the discovery of the element uranium. Analyses of material from different localities exhibit wide variations in chemical composition; in addition to uranium oxides, there are thorium, cerium (and lanthanum), yttrium and lead oxides, each varying in amount from a trace up to 10%. Calcium, iron, magnesium, manganese, silica, water, etc., are also present in small amounts, and the content of uranous and uranic oxides (UO_2, 21–72; UO_3, 13–59%) also vary considerably. The mineral is often described as a uranate of uranyl, lead, thorium and cerium; but in the least altered material from Branchville in Connecticut the uranous oxide predominates, whilst in altered specimens uranic oxide is in excess. In the closely allied mineral, thorianite, thorium predominates (ThO_2, 76; UO_2, 12%). Since the dioxides of uranium, thorium and cerium may be obtained artificially as cubic crystals, it seems probable that pitchblende consists of isomorphous mixtures of these dioxides, the uranic oxide being due to oxidation.

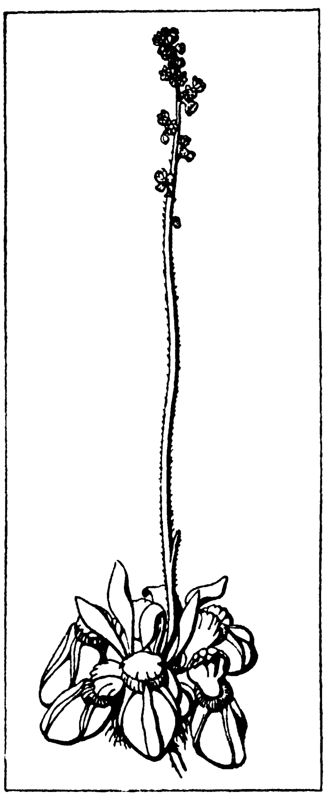
The radio-active properties of pitchblende are of special interest. The fact that this mineral is more strongly radio-active than metallic uranium led to the discovery in it of the elements radium, polonium and actinium. When pitchblende is ignited

or dissolved in dilute sulphuric acid, a gas is evolved which consists largely of helium and argon; terrestrial helium was first recognized in this mineral.

Pitchblende occurs either as a primary constituent of granitic rocks or as one of secondary origin in metalliferous veins. Octahedral crystals ("cleveite" and "bröggerite") occur in the pegmatite veins of southern Norway, being occasionally found in the felspar quarries at Moss, Arendal and other places. Crystals are found under similar conditions at Middletown and Branchville in Connecticut, Llano county in Texas ("nivenite"), Mitchell county in North Carolina, Villeneuve in Quebec, and other American localities. Thorianite, found as water-worn cubes in the gem-gravels near Balangoda in Sabaragamuwa province, Ceylon, has also no doubt been derived from crystalline rocks. On the other hand, the mineral found in metalliferous veins, and to which the name pitchblende is more properly restricted, never occurs as crystals, but as compact masses rendered more or less impure by admixture of other minerals, the specific gravity being sometimes as low as 6·5; thorium, cerium, etc., are absent, and radium and helium are present in smaller amounts. This variety occurs with ores of silver, lead, copper, nickel, cobalt, bismuth, etc., at Johanngeorgenstadt, Marienberg and Schneeberg in Saxony, Jáchymov and Příbram in Bohemia, Gilpin county in Colorado, St. Just, Redruth, Grampound Road and elsewhere in Cornwall, and at Kasola in Katanga, Belgian Congo.

Often associated with pitchblende, and resulting from its alteration, is an orange-yellow, amorphous, gum-like mineral called gummite, which is a hydrous uranic oxide with small amounts of lead, calcium, iron, etc.

PITCHER PLANTS, in botany, the name given to plants in which the leaves bear pitcher-like structures or are pitcher-like in form. The plant generally understood by this name is *Nepenthes,* family Nepenthaceae, a genus containing nearly 60 species, natives of tropical Asia, north Australia and (one only) of Madagascar. North Borneo is especially rich in species. They are shrubby plants climbing over surrounding vegetation by means of tendril-like prolongations of the midrib of the leaf beyond the leaf-tip.



FROM "CURTIS' BOTANICAL MAGAZINE"

PITCHER PLANT (CEPHALOTUS FOLLICULARIS), SHOWING LEAVES, PITCHERS AND TALL FLOWER STEM WITH SMALL FLOWERS

The pitcher is a development at the end of the tendril and is generally tubular in form and often shows a pair of wings running longitudinally on the outer surface. The mouth of the pitcher has a corrugated rim (peristome) formed by incurving of the margin, the convex surface of which is firm and shining. It is traversed by more or less prominent parallel ridges, which are usually prolonged as teeth beyond the infolded margin. Above the mouth is the lid (operculum), which varies in size from a small narrow process to a large heart-shaped expansion. A study of the development of the pitcher, especially in the young pitchers of seedling plants, shows that the inflated portion is a development of the midrib of the leaf, while the wings, which are especially well represented in the terrestrial type of pitcher, represent the upper portion of the leaf-blade which has become separated from the lower portion by the tendril; the lid is regarded as representing two leaflets which have become fused. The short straight or curved process from the back of the pitcher behind the lid represents the organic apex of the leaf.

The size of the pitcher varies widely in the different species, from a thimble to the size of a quart pot. The colour also varies considerably, even in different pitchers of the same individual, according to age, light exposure or soil conditions. Insects are attracted to the mouth of the pitcher by a series of glands, yielding a sweet secretion, which occurs on the stem and also on the leaf from the base of the leaf-stalk to the lid and peristome.

SIDE SADDLE FLOWER (SARRACENIA PURPUREA): SHOWING LEAVES, THE WHOLE OF WHICH FORM THE PITCHERS; AND A, B AND C SHOWING THE MINUTE STRUCTURE OF PITCHERS (A AND C FROM S. FLAVA)

Embedded in the incurved margin of the rim which affords a very insecure foothold to insects are a number of large glands secreting a sweet juice. The cavity of the pitcher is in some species lined throughout with a smooth glistening surface over which glands are uniformly distributed; these glands secrete a watery fluid which is found in the pitcher even in the young state while it is still hermetically closed by the lid. In other species the glands are confined to the lower portion of the cavity surface, while the upper part bears a smooth waxy surface on which it is impossible for insects to secure a foothold. This area is termed the "conducting" area, as distinguished from the lower or "detentive" gland-bearing area. Insects, especially running insects, which have followed the track of honey glands upwards from the stem along the leaf, reach the mouth of the pitcher, and in their efforts to sip from the attractive marginal glands fall over into the liquid. The smooth walls above the liquid afford no foothold, owing to the presence of minute waxy scales, and they are drowned. The fluid, as first secreted, is not acid and contains no digestive enzyme, but the presence of an insect causes the glands to secrete both acid and a proteolytic (protein-dissolving) enzyme. The bodies of the insects are thus digested and the products of digestion absorbed by the glands in the pitcher-wall. Thus *Nepenthes* secures a supply of nitrogenous food from the animal world in a manner somewhat similar to that adopted by the British sundew, butterwort, and

other insectivorous plants. In spite of the presence of a digestive enzyme, the pitchers constantly contain an association of living organism desmids, diatoms, *Acarina*, larvae of Diptera, etc.

The side-saddle plant, *Sarracenia*, native of the eastern United States, is also known as a pitcher-plant. There are about seven species, herbs with clusters of radical leaves some or all of which are more or less trumpet- or pitcher-shaped. The leaf has a broadly sheathing base succeeded by a short stalk bearing the pitcher, which represents a much enlarged midrib with a wing-like lamina. Above the rim of the pitcher is a broad flattened lid, which is also a laminar development. The surface of the leaf, especially the laminar wing, bears glands which in spring exude large glistening drops of nectar. The lid and mouth of the pitcher are brighter coloured than the rest of the leaf, which varies from yellow-green to deep crimson in different species and in individuals according to exposure to sunlight and other conditions. This forms the attractive area, and the inner surface of the lid also bears a large number of glands, as well as downward-pointing hairs, each one having a delicately striated surface.

Below the lid is the conducting surface of glassy epidermal cells, with short downward-directed points, which facilitate the descent, but impede the ascent of an insect. Then come the glandular sur-

face, which is formed of smooth polished epidermis with numerous glands that secrete the fluid contents of the pitcher, and finally the detentive surface, of which the cells are produced into long and strong bristles which point downwards and meet in the centre of the diminishing cavity so as to render escape impossible. The secretion wets an insect very rapidly, but its digestive power is uncertain. The pitchers accumulate vast quantities of insects in the course of a season, and must thus abundantly manure the surrounding soil when they die. Moreover, the feast is largely shared by unbidden guests. Not to speak of insects which feed upon the pitcher itself, some drop their eggs into the putrescent mass, where their larvae find abundant nourishment, while birds often slit open the pitchers with their beaks and devour the maggots in their turn.

Cephalotus follicularis, a native of south-west Australia, a small herbaceous plant, bears ordinary leaves close to the ground as well as pitchers The latter somewhat resemble in general form

PITCHER PLANT (NEPENTHES BICALCARATA), A PLANT WITH PITCHERS ONLY AT THE END OF THE LEAVES

those of *Nepenthes*. The lid is especially attractive to insects from its bright colour and honey secretion; three wings lead up to the mouth of the pitcher, on the inside of which a row of sharp spines points downwards, and below this a circular ridge armed with papillae serves as a conducting area. A number of glands on the interior of the pitcher secrete a fluid in which insects are found but how they are utilized is still obscure.

For further details, *see* K. Göbel, *Pflanzenbiologische Schilderungen* (Marburg, 1889–93); F. Knoll, "Über die Ursache des Ausgleitens der Insektenbeine an wachsbedeckten Pflanzenteilen," *Jahrb. f. wiss. Bot.* (1914); J. S. Hepburn, "A Study of the Protease of the Pitcher Liquid of *Nepenthes*," *Contrib. Bot. Lab. Univ. Penn.* (1919); P. van Oye, "Zur Biologie der Kanne von *Nepenthes melamphora*," *Biol. Centralbl.* (1921).

PITCHSTONE, in petrology, a glassy igneous rock having a resinous lustre and breaking with a hollow or conchoidal fracture (Ger. *Pechstein,* from its resemblance to pitch). It differs from obsidian principally in its rather dull lustre, for obsidian is bright and vitreous in appearance; pitchstones also contain water in combination amounting to from 5 to 10% of their weight or 10 to 20% of their volume. The majority of the rocks of this class occur as intrusive dikes or veins; they are glassy forms of quartz-porphyry and other dike rocks. Their dull lustre may be connected with the great abundance of minute crystallites and microlites they nearly always contain; these are visible only in microscopic sections, and their varied shapes make pitchstones very interesting to the microscopist.

Although pitchstones of Devonian age are known (*e.g.*, the glassy dacite of the Tay Bridge in Scotland, and the andesite-pitchstones of the Cheviots), most of them are Tertiary or recent, as like all natural glasses they tend to crystallize or become devitrified in course of time. In some of the older pitchstones the greater part of the mass is changed to a dull felsitic substance, while only nodules or kernels of unaltered glass remain. Some are very acid. containing 70 to 75% of silica, and have close chemical affinities to granites and rhyolites; others contain more alkalis and less silica, being apparently vitreous types of trachyte or keratophyre; others have the composition of dacite and andesite, but the black basaltic glasses are not usually classified among the pitchstones. Very well known rocks of this group occur at Chemnitz and Meissen in Saxony. These rocks are brown or dark green in colour, very frequently perlitic, and show progressive devitrification starting from cracks and joints and spreading inwards through the mass. For a long time the pitchstone dikes of Arran, Scotland have been famous for the great beauty and variety of skele-

ton crystals they contain; they are dull green in hand specimens; some of them contain phenocrysts of felspar, augite, etc., others do not, but in all there is great abundance of branching feathery crystalline growths in the ground mass, minute crystalline rods being built together in aggregates which often recall frost patterns. It is supposed that they consist of hornblende. In addition to these larger growths there are many small microlites scattered through the glass, also hair-like trichites, and fine rounded globulites. When phenocrysts are present the small crystals are planted on their surfaces like grass on a turf-covered wall. These pitchstones are believed to proceed from the great eruptive centres of early Tertiary times in western Scotland. Another pitchstone of the same period forms a great craggy ridge or scuir in the island of Eigg (Scotland).

In chemical composition this latter rock resembles the trachytes rather than the rhyolites; in Eigg and Skye there are many dikes of pitchstone, mostly of intermediate rather than of acid character, all connected with the great eruptive activity which characterized that region in early Tertiary times.

The following analyses give the chemical composition of a few well-known pitchstones:—

bishop (10th), formed the nuclei of the town; and the donjon built in the 10th century for Héloïse, lady of Pithiviers, was one of the finest of the period.

PITHOM, one of the "treasure cities" stated to have been built for Pharaoh by the Hebrews in Goshen during the Oppression (Exod. i. 11). We have here the Hebraized form of the Egyptian Petōm, "House of (the sun-god) Etōm," in Greek, Patūmos, capital of the 8th nome of Lower Egypt and situated in the Wadi Tumilat on the canal from the Nile to the Red Sea. Succoth (Egyptian Thuket) was identical with it or was in its immediate neighbourhood. The site, now Tell el Maskhuta, has yielded several important monuments, including the best preserved of the trilingual stelae of Darius which commemorated his work on the canal.

PITIGLIANO, a town in Italy, province of Grosseto. Pop. (1921), 5,845. It is the cathedral city of the bishopric named after the neighbouring town of Sovana, and was originally a fief of the countship of Sovana, which in 1293 came by marriage into the possession of the Orsini. In 1410 Sovana was taken by the Sienese, but the Orsini retained Pitigliano, Gentile Orsini assuming the title of count. In 1562 the Medici of Florence seized part

	SiO_2	Al_2O_3	Fe_2O_3	MgO	CaO	Na_2O	K_2O	H_2O
I. Meissen, Saxony	72·42	11·26	0·75	0·28	1·35	2·86	3·80	7·64
II. Corriegills, Arran	72·07	11·26	3·24	tr.	1·53	0·61	5·61	5·45
III. Scuir of Eigg, Scotland	65·81	14·01	4·43	0·89	2·01	4·15	6·08	2·70

The first two of these contain much water for rocks the ingredients of which are but little decomposed. They are of acid or rhyolitic character, while the third is richer in alkalis and contains less silica; it belongs more naturally to the intermediate rocks (or trachytes). (J. S. F.)

PITE, WILLIAM ALFRED (1860–), F.R.I.B.A., British architect, was born on Aug. 4, 1860 in London. He studied at the National Art Training School, afterward winning several studentships. Later he became vice-president of the Architectural Association, and examiner and member of council of the R.I.B.A. His works include an important series of hospitals in London and the provinces, including King's College Hospital; three churches, of which the Perceval Memorial church at Ealing is perhaps the most interesting, and a number of private houses.

PITEŞTI. The capital of the department of Argeş, Rumania; beautifully situated among the outlying hills of the Carpathians, on the river Argeş, which is here joined by several smaller streams, and on the junction of the main Bucharest-Craiova line with branches to Câmpulung and Curtea de Argeş. Pop. (1928) 25,000. The surrounding uplands produce good wine, fruit and grain, and are rich in petroleum and salt; the town is a centre of the petroleum industry. It has lacquer and varnish mills and distilleries.

PITHECANTHROPUS, the name given by Dr. Eugene Dubois, of the Dutch army medical service, to the creature (*P. erectus*) of which he found fossilized remains in Java. These fragments consisted of a thigh-bone, two teeth, and the upper part of a skull, and were unearthed in 1891–92 on the left bank of the Bengawan river near Trinil. The skull appears to have been low and depressed with strong supraciliary ridges; the teeth are very large, and the femur is quite human. The teeth and skull were found together, the femur a few yards away a year afterwards. The discoverer, however, stated it as his belief that the fragments were portions of the same skeleton and belonged to a creature half-way between man and the higher apes and of the Pleistocene age, and, in spite of opposition, is now admitted.

See Dubois, *Pithecanthropus erectus* (1894); a later paper read by Dr. Dubois before the Berlin Anthropological Society, translated in 1898 *Smithsonian Report;* Sir A. Keith, *Antiquity of Man* (1915).

PITHIVIERS, a town of north central France, in the department of Loiret, 28 m. N.N.E. of Orleans, on the railway to Malesherbes. Pop. (1926) 5,540. The town is an important centre for the saffron of the region of Gâtinais. The shrines of St. Solomon (9th century) and of St. Gregory, an Armenian

of their territories, and acquired the rest by exchange in 1580. The Orsini stronghold still stands in the town, which is perhaps identical with the Etruscan Statonia.

PITLOCHRY, village of Perthshire, Scotland, 28½ m. N.W. of Perth by the L.M.S. railway. Pop. (1921), 2,241. It lies on the left bank of the Tummel, a little below the confluence of that river and the Garry, 350 ft. above the sea. It is a tourist centre.

PITMAN, SIR ISAAC (1813–1897), English phonographer, was born at Trowbridge, Wiltshire, on Jan. 4, 1813. He started in life as a clerk in a cloth factory, but in 1831 he was sent to a training college for teachers. After eleven years of teaching in elementary schools he opened a private school in Bath. In 1829 he took up Samuel Taylor's system of shorthand, and became an enthusiast in developing the art of phonography. In 1837 he drew up a manual of Taylor's system and offered it to Samuel Bagster (1771–1852). The publisher did not accept the work, but suggested that Pitman should invent a new system (*see* SHORTHAND) of his own. The result was his *Stenographic Soundhand* (1837). Bagster's friendship and active help had been secured by Pitman's undertaking to verify the half-million references in the *Comprehensive Bible*, and he published the inventor's books at a low price, thus helping to bring the system within the reach of all. Pitman established at Bath a Phonetic Institute and a *Phonetic Journal* for this purpose; he printed in shorthand a number of standard works, and his book *Phonography* (1840) went through many editions. He was an enthusiastic spelling reformer, and adopted a phonetic system which he tried to bring into general use. In 1894 he was knighted. He died at Bath on Jan. 12, 1897. Isaac Pitman's system revolutionized the work of reporting.

His Life was written in 1902 by his brother Benn Pitman (1822–1911) and by Alfred Baker in 1908.

PIT PONY. The pit pony is usually a small pony—14 hands high and under—used for hauling the tubs for the conveyance of coal from the working face of the coal seam to a point, variously termed the "flat," "double-parting," "station" or "landing," where the tubs are made up into "sets" or trains and conveyed, either by horses or, more commonly, by mechanical haulage, to the shaft bottom. That is to say, the pit ponies ply between the face and flat, bringing the full tubs out from the hewer and serving him with empty tubs.

The use of pit ponies has decreased with the extended development of electrically driven haulage underground.

The care and treatment of horses and ponies at mines in the United Kingdom are the subject of stringent provisions in the Coal Mines Act, 1911 (third schedule).

PIT-SHAFT: *see* COAL AND COAL MINING.

PITT, THOMAS (1653–1726), British East India merchant and governor of Madras, usually called "Diamond Pitt," was born at Blandford, Dorset, on July 5, 1653. From his headquarters at Balasore, he engaged in trade in opposition to the East India Company, whom he opposed also in the law courts. Unable to check him the East India Company took him into its service in 1695, and in 1697 he became president of Fort St. George, or Madras. While in India Pitt bought the fine diamond which was named after him; in 1717 he sold this to the regent of France, Philip duke of Orleans, and it is now the property of the French government. During his stay in England Pitt acquired the manor of Old Sarum, and for a short time he represented this borough in parliament. After his final return from India in 1710 he again became member of parliament for Old Sarum. He died at Swallowfield, near Reading, on April 28, 1726. His eldest son, Robert, was the father of William Pitt, earl of Chatham (*q.v.*); and of Thomas Pitt (d. 1761), whose son became the first Lord Camelford; his second son, Thomas Pitt (*c.* 1688–1729), having married Frances (d. 1772), daughter of Robert Ridgeway, 4th earl of Londonderry (d. 1714), was himself created earl of Londonderry in 1726.

See Sir C. N. Dalton, *Life of Thomas Pitt* (1915).

PITT, WILLIAM (1759–1806), English statesman, second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, was born at Hayes, near Bromley, Kent, on May 28, 1759, in the year of the pinnacle of his father's glory. Both because of his extreme delicacy and because his father was an early critic of the public school system, he was educated at home under the tutorship of the Rev. Edward Wilson of Pembroke Hall, Cambridge, and the earnest supervision of Chatham himself—a plan which tended to the intensive development of the child's unusual precocity. Before he was ten years old he was a good classical scholar: at 13 he had composed a strange political tragedy *Laurentino, King of Chersonese.* In Oct. 1773, in his 15th year, he went into residence at Pembroke Hall, Cambridge, where his tutor was the Rev. Dr. George Pretyman (he changed his name in 1803 to Tomline), to whom Pitt in later years awarded the bishopric of Lincoln, and at the last bequeathed his papers: and who in return became his pupil's first biographer. Pitt had not been at Cambridge long when he fell seriously ill and was obliged to return home. It was then that the family physician, Dr. Anthony Addington prescribed that generous consumption of port wine which was to become the habit of a life. He returned to Cambridge in July 1774; and in 1776, by the privilege of his birth as the son of a peer, graduated as a master of arts without examination. That year saw the Declaration of American Independence, and the next the battle of Saratoga. On April 7, 1778 Pitt was the witness of his father's last dramatic utterance in the House of Lords. A month later Chatham died. Pitt was left with an income of £300 a year; he began to keep his terms at Lincoln's Inn; was called to the bar on June 12, 1780 and joined the western circuit. At the general election in September Pitt was defeated for the University of Cambridge but was returned for Sir James Lowther's pocket borough of Appleby. He entered parliament on Jan. 23, 1771: he was not yet 22 years old.

Parliament.—Pitt was attached to that section of the opposition which had followed his father, and was now led by Lord Shelburne. His maiden speech on Feb. 26 was made in support of Burke's Bill for economical reform, and produced a series of famous eulogies, Lord North admitting it the best first speech he had ever heard, and Burke, with even greater prodigality, declaring him "not a chip of the old block but the old block itself." A year later, when North's ministry was near its fall, Pitt had the self-confidence to announce in the House of Commons (March 8, 1782) that, should he conceivably be asked to join the new ministry, he would never accept a subordinate position in it; nor did he alter his mind when Rockingham, shortly afterwards offered him certain well-paid but unimportant posts, and even though one of them—the vice-treasurership of Ireland—had been held by Chatham before him.

As a private member Pitt now supported a new version of Burke's reform project, a measure for shortening the duration of parliaments, and another for destroying bribery at elections. On May 7 he presented his own motion for a select committee to inquire into the state of the representation. It was only defeated by 20 votes. Shortly afterwards the death of Rockingham on July 1 provoked a major crisis. The king appointed Shelburne as his successor. Fox, Lord John Cavendish and Burke immediately refused to serve with him; whereupon Shelburne turned to Pitt, who on July 6 accepted the office of chancellor of the exchequer.

The Shelburne Ministry.—The ministry was only to last until the following February. On Jan. 20, 1783, the preliminaries of the Peace of Versailles were signed, and provided the opposition with an easy target. It was essential for Shelburne to obtain more support, and on Feb. 11, by agreement with his chief, Pitt visited Fox to invite him to return to the ministry. Fox replied that he would only serve on the condition that Shelburne resigned the premiership, whereupon Pitt replied "I did not come here to betray Lord Shelburne." The incident is important. It marks the beginning of the ceaseless political warfare between Fox and Pitt; it marks the end of the Shelburne ministry, and the origin of the coalition between Fox and North. Speaking of North's Government only in the previous year, Fox had declared "From the moment when I shall make any terms with one of them, I will rest satisfied to be called the most infamous of mankind," and he had loudly demanded their impeachment: yet he who had poured his blistering scorn upon North's conduct of the war, now joined with North in execrating the terms of the peace. The ministry was defeated (Feb. 21) and two days later Shelburne resigned. For a month the king sought to escape the coalition. But Pitt, who was pressed to accept the Treasury preferred to bide his time, and North could not be lured from Fox. On April 2 the Fox-North coalition under the nominal leadership of the duke of Portland took office.

The Coalition Ministry.—On May 7 Pitt brought forward resolutions for checking bribery at elections, disfranchising corrupt constituencies, and increasing the number of county and London members of parliament. The resolutions were refused by 293 to 149. On June 2 he brought forward another bill which passed the Commons but failed in the Lords, for reforming abuses in public offices: he instanced North's mysterious consumption of stationery, which totalled £1,300 and contained an item of £340 for whipcord.

During September and October Pitt visited France—his only venture outside his own country. In November parliament reassembled and Fox immediately introduced his India bill. Passed in the Commons the measure was defeated in the Lords (Dec. 17) because George III. plainly informed the peers at large through Lord Temple that he should regard anyone who voted for the bill as his enemy. The Government very properly refused to resign. Whereupon the king, on Dec. 19, depending upon a barely literal interpretation of his constitutional rights, but reflecting by accident the wishes of his people, dismissed his ministers and appointed Pitt as first lord of the treasury and chancellor of the exchequer. The coalition had been jockeyed out of office, and it is not surprising that the House received the news of Pitt's appointment with mirth. It is mistakenly generous, however, to suppose that Pitt assumed office from pure altruism and without a certain confidence in the future. The strident Opposition no longer represented its constituency and Pitt knew it, and while they were wasting their breath deriding the "boyish prank," Pitt was converting the electorate—voters who were to be more valuable to him than the voters in the House of Commons. Almost as important, the influence of the City and of the East India Company was on his side. Until the end of March he struggled on, continually defeated in the House, but steadily refusing to resign. Outside his popularity was growing, while the action of the Opposition in threatening to oppose even the votes of supply cast on them the obvious accusation of factiousness. The hostile majority diminished daily until on March 8 Fox's "representation" was carried by only one vote. On March 24 parliament was dissolved. The essential business had been forced

through. At the ensuing election some 160 of "Fox's Martyrs" were rejected. This was the answer to the charge of unconstitutional action: throughout the struggle Pitt had in fact represented the nation. Pitt was himself elected for Cambridge university, which he represented for the rest of his life.

PITT'S FIRST MINISTRY

Finance.—Finance was the first consideration. There was a heavy debt and the fiscal machinery was antiquated. Pitt floated a loan of £6,000,000, offering the tenders to public competition, and funded £6,600,000 of the floating debt. The loss to the revenue which had long resulted from the systematic evasion of the high protective tariffs he countered by a radical reduction of duties—that on tea being reduced from 119% to 12%. To meet the loss he increased the window tax, and many new taxes were instituted to touch the whole people. But he withdrew the tax on raw cotton, and pronounced it as his principle that "manufactures in general ought to be free from taxes."

Pitt, who had been one of the earliest students of Adam Smith, next attempted the establishment of free trade between England and Ireland. The Irish accepted his propositions (Feb. 7, 1785) but in England the measure was met by the organized opposition of vested interest, prejudice, and faction. Pitt was obliged to alter his original scheme, and in that form the Irish, disappointed and inflamed by Fox's subtle tongue, rejected it.

In 1786 Pitt introduced his sinking fund, a measure adapted from a scheme of Dr. Richard Price (*q.v.*). Economically it was undoubtedly mistaken, but it was believed to be a sovereign remedy, and it at least inspired public confidence.

On April 18, 1785, Pitt brought forward a bill proposing to suppress 36 pocket boroughs and to transfer their members to increase the representation of certain towns and counties. £1,000,000 was to be spent upon the purchase of the interests of the various owners. The bill, for which he eloquently pleaded, was rejected by 248 to 174.

India.—Pitt's India Bill, which had been rejected during the first struggle in the spring of 1784, was passed in the summer easily enough. Pitt's bill, unlike Fox's, left the ordinary patronage with the directors of the company while passing to the Crown the political control. Moreover, he had the tact and the wisdom to consult the company and to present as a final draft a measure to which he knew they were prepared to agree. The bill was not without serious defects—especially in its subordination of the governor-general not only to his council, but in all important concerns to the home Government. Warren Hastings resigned at once, and upon his return, his conduct of the Government was called in question. Pitt who had voted against the Rohilla charge (which was not carried) voted in favour of the Benares and the Begum charges. His action decided the issue. The motions were carried, and the impeachment pursued. Pitt has been heavily criticised for his conduct. But the truth that Hastings had been a great administrator could not disguise the fact that here was a patent scandal, which demanded inquiry. Indeed Hastings, through his agent in the House, had himself originated the discussions; and Pitt deliberately chose to support the Opposition in a matter where he honestly believed them to be right, instead of following the usual custom of opposing whatever measure the Opposition proposed.

The Regency Question.—In Nov. 1788 the king's illness provoked a crisis which might have ended Pitt's political career. There was a traditional enmity between the Hanoverian monarchs and their sons, and the whole influence of the prince of Wales (doubly hostile because Pitt would not pay his debts), was directed to the cause of the Whigs. The king being insane it was essential to appoint a regent, and Pitt was inevitably agreed that there could be no other candidate for the office than the prince of Wales. The point at issue lay in the claim of Fox and his party that the prince had a prerogative right to the position. Pitt claimed that he could only become regent by act of parliament, and drew up that act so as to restrain the regent from making peers or granting pensions, while the king's person and household and the patronage of the Crown were to be placed under the direction of the queen. The bill passed the Commons (Feb. 5, 1789) and while it was under discussion in the Lords the king recovered. The situation had been dangerous, for though the resolutions had been carried, there had been much uneasiness among Pitt's followers. Pitt himself believed that he would be unable to retain office and would have to resume work as a lawyer. The London merchants at this time offered him £100,000 in recognition of his conduct, but Pitt replied that "No consideration on earth shall ever induce me to accept it." At the general election of 1790 he obtained an increased majority. In April 1791 by his Constitutional Act he arranged for the division of Canada into Upper and Lower Canada. The following year he accepted the wardenship of the Cinque Ports which carried a salary of £3,000 a year.

Foreign Policy.—The first important act of Pitt's foreign policy—the commercial treaty with France—was complementary to his reorganization of the home finances. The abandonment of useless trade restrictions was plainly to the benefit of both countries and Fox could think of no better ground of attack than to assert that France was the unalterable enemy of England, to which objection Pitt replied that "to suppose that any nation could be unalterably the enemy of another is weak and childish." In 1787 there was trouble in Holland. The Emperor Joseph II. had been for some time preparing a labyrinthine scheme whereby he should consolidate his dominions by annexing Bavaria, whose elector was to be compensated in the Austrian Netherlands. The scheme was agreeable to France who was intriguing for the overthrow of the Dutch stadholder and complete influence in Holland. War was only avoided after full preparations had been made (an expedition for instance was actually prepared for the capture of the Cape) because Prussia, who was opposed to Joseph II.'s policy was at length persuaded to stand with England. Upon Prussia's entry into Holland the Austro-Russo-French intrigue collapsed and the stadholder was restored. In 1789 England was brought into conflict with Spain who had seized the British trading post at Nootka Sound. Again war seemed imminent (over two millions sterling were spent in naval preparations), but Spain, receiving no support in Europe, was obliged to withdraw. Less successful was Pitt's intervention in the Eastern question. Catherine II. of Russia was at war with Sweden and Turkey. The Triple Alliance (of England, Prussia and Holland) had gained a prestige which placed it in a position to work for the maintenance of the balance of power. But though Austria's support was detached from Russia and Gustavus III. made peace with Catherine, the empress was not to be diverted from her ambitions in Eastern Europe. She gained great success in 1791, and Pitt, without adequate means of supporting his policy, determined to prevent Russia from establishing her power in the Black sea. He demanded that Russia should give up Oczakov, but Oczakov meant nothing on earth to the British public, and Catherine perceiving there was no force behind the ultimatum was unmoved by it. Though armament credits had been voted, Pitt was obliged to retire.

Pitt had not at first anticipated that the French Revolution would involve England in hostilities. In the spring of 1792 he was happily discussing finance, prophesying the reduction of 25 millions of debt in the next 15 years, and declaring in support of his vision that "there never was a time when, from the situation of Europe, we might more reasonably expect 15 years of peace than we may at the present moment." He had no intention of interfering in a matter which concerned France alone, and indeed in its original conception he was not unsympathetic to the aims of the Revolution. On Aug. 10th, the French monarchy fell, and the English ambassador was recalled from Paris, and Chauvelin in London could henceforward be only received unofficially. But this was merely a question of diplomatic routine: friendly relations were not strained until the French, having already declared war upon Austria and Prussia, followed the victory of Jemappes by occupying the Austrian Netherlands, threatening Holland, and overturning the treaties which governed the navigation of the Scheldt. England was bound by treaty to support Holland; and, as she had been through the centuries, she was not less insistently bound in this matter by her own interests. The execution of the king, and among the French people a rising tide of truculence swiftly fol-

lowed. On Feb. 1, while Pitt was outlining the provocations which Britain had received from France that country was despatching yet another in the shape of a declaration of war. The remainder of Pitt's life was to be spent in the shade of the revolutionary wars.

War.—The history of the wars with France is discussed under FRENCH REVOLUTIONARY WARS, NAPOLEONIC CAMPAIGNS, NAPOLEON; FRANCE, etc. It is only possible here to estimate generally the part that Pitt played in the organization of Europe. It has long been a current *cliché* to say that Pitt was a great peace minister and a poor war minister. But if Pitt's talents were indeed essentially suited to peace, it is equally true that Napoleon was finally encompassed in disaster by the dogged determination of the English premier, and after his death by the remembered influence of that resolution. To compare him with his father is idle; Chatham had every advantage. His allies were great commanders, his France was effete. But revolutionary France was inspired with a fanatic hope, and England's continental allies proved continually worthless. Year after year Pitt laboured to sustain his coalitions of the Powers; year after year the coalitions melted away before the victorious advances of the French. England, who had no call to be anything but a member of a general European league against France was forced to be the inspiration as well financially as politically of the entire organization.

Home Policy.—At home the war changed entirely the tranquil prospects of national wealth and prosperity. New voices were in the air—voices of political discontent, and shortly the voices too of hunger. Pitt's policy at home at this juncture is of great importance. Because he never again brought forward the question of reform after his failure in 1785, and opposed it whenever it was proposed by others, his sincerity has been openly called in question. His actions certainly demand some explanation. It is in the first place important to admit that there was as yet no national enthusiasm for reform: the cry had been raised largely in protest against the unconstitutional behaviour of the king, and had been lulled since the declaration of peace; moreover those who had been foremost in urging "economical reform" had no such belief in the necessity of parliamentary reform. A statesman—especially one on whom practically the whole conduct of a Government devolves—can not persist in a measure which has been again and again rejected in one form or another. Pitt had a large majority. But the fact that he remained in office for so long has obscured the truth that he was to a very large extent dependent upon the caprices of that majority. A contemporary political estimate recorded the number of those gentlemen who "would probably support his majesty's Government"—roughly the Court Party—as more than three times the size of Pitt's personal party: and there was a further shifting and entirely independent vote For all his dominance of the House Pitt was sometimes defeated—over the Westminster petition (*see* FOX, CHARLES JAMES), over Ireland, over his proposals in 1786 to fortify Plymouth and Portsmouth. The demand for reform was not seriously supported in the House of Commons. More important still it was not as yet properly vocal outside its walls.

In 1792 Tom Paine's *Rights of Man* had been published, suddenly jolting the English Radical movement into a new mind at the moment when the French doctrines were filtering into England in a fashion admittedly designed to provoke dissensions. The circumstances had become altered. Pitt's refusal to support the motion for the repeal of the Test and Corporation Acts in 1789 and 1790 was unintelligibly craven; but when he refused to support Grey in 1792 he had excuse. "The hurricane season" had set in. Pitt allowed himself to be stampeded by a species of panic which was entirely unjustified by the facts. Talleyrand at this time remarked that those curiously deceived themselves who believed that England was on the verge of revolution. He was a more shrewd observer of truth—but it must be admitted that he had the advantage of looking at Britain not only in perspective but also dispassionately. Deceived or not, Pitt declared that this was no time to revise a constitution, and proceeded to punish severely any who should advocate reform doctrines. It was lamentable; it was essentially unjust; and there is but one excuse—the excuse which in sympathy has condoned many shameful persecutions, when things are done in panic which are never justified by the patent facts but are believed to be necessary for profound reasons of State that can only be guessed at.

In 1793, and again in 1795–1801 *Habeas Corpus* was suspended, and bills for the suppression of sedition followed. There succeeded the trials and transportations of men like Skirving, Margarot, Gerrald, Muir, condemned for nothing more treasonable than advocating parliamentary reform or universal suffrage. Societies for constitutional reform were raided and suppressed. It is unpleasant to find that the records of the confiscated papers of those clubs reveal without exception nothing indicative of revolutionary organization. And yet in 1795 Pitt declared that were he to resign he would lose his head within six months. The circumstances were extraordinary, and it is just to suppose that Pitt was honest: he was not the less grievously wrong.

It was not long before the pain of war was felt in England. Pitt had based his confidence in a short period of war upon the pathetic belief that France would be financially incapable of sustaining a prolonged struggle. But the war advanced, and Pitt's subsidies were swallowed up upon the Continent by allies who made little or no return for them. The nation's debt mounted. The coalition crumbled. More money to buy more allies was needed In 1795 after a season of bad harvests Pitt had to ask for a loan of 18 millions, and to increase the general taxation. Shortly afterwards followed the legacy duties. In 1797 taxation was increased by two millions; the next year produced the income tax

Ireland.—One of Pitt's major pre-occupations was still Ireland. He had failed in 1785, but he never ceased to plan for the final consummation of his hopes. In 1793 Pitt forwarded the passage in the Irish House of Commons of the Catholic relief bill; but in 1794 he suffered disappointment when Irish opinion was again alienated by the position he was forced to adopt against the antics of Lord Fitzwilliam, who had been made lord lieutenant as a concession to the Portland Whigs who had entered the ministry in that year. Fitzwilliam and his party were anxious for a broad policy of reform and emancipation; but Pitt had laid down a cautious line of action, and it had been determined that Fitzwilliam should do nothing without the consent of the cabinet. But by "an open breach of a most solemn promise" he proceeded to dismiss the Irish Tory officials, and without authorization to promise widely the immediate prospect of a full emancipation. Fitzwilliam was recalled, and Ireland left to nurse an angry grievance. The whole bungling led directly to the disasters which followed; the state of semi-civil war in 1797 and the rebellion of 1798 and that disaffection which could welcome the French invasion. The union of Ireland and England which he had sought earlier for the mutual benefit of both countries was now imperative as a solution to a state of war. On Jan. 23, 1799, Pitt brought forward his proposals for a union of the two countries. Emancipation was not promised (the hostility of George III.'s eccentric conscience precluded the suggestion) but the hope was held out that this would follow in due course. The bill was pressed through the Irish parliament by Cornwallis, the viceroy, and Castlereagh, the secretary for Ireland. The distribution of titles and money played some part in this and more than a million pounds was expended in compensation to the holders of suppressed rotten boroughs. However open to moral criticism the latter decision may have been, it was essential to the support of the bill and it destroyed an entirely dishonest system of representation. As for the measure of the general corruption, that has at least been over-estimated, and in so far as material persuasion was adopted it must be remembered that bribery in the Irish parliament was a deeply respected tradition. Moreover it must have been patent to the guiding minds in Ireland that the present state of affairs was impossible, and the possible benefits of the union, for instance to trade, were obvious. The bill having passed the Irish parliament in 1800, the first united parliament met in Jan 1801. Pitt had now to enlarge his policy, and once more the solution of Ireland's troubles was tragically postponed. Pitt had not promised emancipation, but those who had voted for the measure had been led to expect that it must follow. With a secrecy which

was perhaps unwise but understandable in the circumstances Pitt drew up his preliminary suggestions for the abolition of religious tests, the commutation of tithes, and provision for Catholic and dissenting clergy. The plan was opposed in the cabinet, principally by Lord Loughborough, the chancellor, who reported the matter to the king. George was enraged, and adamant against the proposals, and on Feb. 5 accepted the resignation which Pitt had tendered on Feb. 3. Immediately afterwards the situation was complicated by the king's relapse. During his temporary insanity, Pitt retained office until his recovery, finally resigning on March 14. Many bitter things were spoken of him. Once again he was accused of betraying his cause. But he had boldly brought forward his reforms, and his resignation followed upon their veto. Had he pressed his legislation, the king would have persisted inevitably in his opposition: moreover with the war going extremely ill it was not the moment to precipitate a domestic crisis. His promise to George never again to introduce the subject during the reign was sentimental, not necessary, and politically unwise. But he made it because the king had accused him of causing his illness and after all he might reasonably expect that the reign would be shortly finished. That Pitt intended to return to the fullest implications of his project is certain. But he himself had only five more years to live.

1801–1806

Retirement.—Henry Addington, who was called upon to lead the Government, had been universally praised as an expert speaker of the House of Commons; but he was no statesman. Pitt promised to do all he could to support Addington, and generously assisted in the conduct of negotiations for the Peace of Amiens. These terms which Grenville branded as "disgraceful and ruinous" appeared in general "highly satisfactory" to Pitt. Though he had long been anxious to conclude any peace which was at all reasonable, it is difficult to justify him in supporting a peace which recognized the failure of the coalitions to establish the independence of the Netherlands—which had been the ostensible *casus belli.* On the other hand there is evidence that Pitt was conscious of the unstable nature of the peace, and foresaw that a greater struggle was probable. The public supported the peace; and during the discussions a severe vote of censure upon Pitt was rejected, and a counter motion passed by 211 to 52 declaring that he had "rendered great and important services to his country, and deserves the thanks of the house." He retired now from parliament for the space of about a year, living largely at Walmer Castle, where as warden of the Cinque Ports he organized with great diligence and enthusiasm a local volunteer force. The brief interval gave an opportunity too for the examination of his debts. Pitt who had been so astute in public economy was careless of his own. He who had scornfully demanded an explanation of Lord North's expenditure of £340 of public money on whipcord, had himself to account for the grotesque item of £600 for hats. Both thoughtless and generous, Pitt was the victim of swindlers, and in 1800 already owed £45,000 despite the fact that he had received a salary of over £10,000 for many years. He nevertheless refused an offer of £100,000 from the citizens of London, and a gift of £30,000 from the king, though he accepted £11,700 as a loan from a committee of private friends; he was obliged to sell his house Hollwood.

Addington had won a great victory at the general election, but it was not long before his policy began to drift towards perilous courses. When it was clear that a rupture of the peace was imminent, Pitt was approached, but he no longer felt that Addington's policy could receive his honest support, and later negotiations provoked so wide and insistent divergencies of mind upon the personnel of a possible cabinet as to make agreement impossible and even to interrupt an ancient friendship. War broke out again on May 16, 1803. Against the insufficient programme of the ministry Pitt opposed a vigorous policy in a speech (May 23) which provoked the enthusiasm of all parties. But while the cleavage was growing plainer and plainer Pitt yet refused directly to oppose Addington, to whom he had promised his support. The situation was becoming increasingly serious. In the face of the growing danger of invasion the measures of the Government were entirely inadequate, and early in 1804 Pitt was forced into stronger opposition. Complicated once again by a threatened relapse of the king, negotiations for a stronger administration were protracted. The ministry was doomed when a motion of Fox's for a committee of enquiry into the national defences was powerfully supported by Pitt, and after some days of negotiation he returned as chancellor of the exchequer and first lord of the treasury on May 10.

Second Ministry.—Pitt's second term of office was marked by no great enterprises of governance. The war alone absorbed his energies. The labour and the inspiration of the great European coalition again rested exclusively upon Pitt, and his health, now gravely undermined, was beginning to break beneath the strain when early in April 1805 he suffered the pain of witnessing the public disgrace of his old friend and colleague Dundas (Lord Melville, *q.v.*). The battle of Trafalgar (Oct. 21) destroyed the possibility of invasion; but the year closed in disaster. The capitulation of Ulm (Oct. 20) was succeeded by Austerlitz (Dec. 2). At first Pitt was able to doubt the full implications of the news; but, gradually as despatches authenticated the reports he came to realize that the mighty coalition was hopelessly broken. England had saved herself by her exertions, he had remarked at the Lord Mayor's banquet in the previous November: she would save Europe by her example. And now Napoleon stood without a force to oppose him upon the whole continent; and Pitt, with prophetic accuracy, was brought to the bitter admission that the map of Europe would "not be wanted these ten years." On Jan. 23, 1806, he died, and if his last words were not "My country! How I leave my country!" his thoughts can have been none other.

Constitutional Importance.—The period of Pitt's government covered a supremely important moment of political transition. It was also a period of a not less important crystallization of British constitutional doctrine. It would be wrong-headed to attribute that growth too strongly to Pitt's political acumen. Both the length, and the critical instant, of his ministry made development natural and inevitable. He was placed in the position of leadership at precisely the tactical moment. The fruit was ripe: but it was the harvest of a century of other men's labours. Pitt was the first Hanoverian minister to appeal definitely from the vote of the House of Commons to the vote of the constituencies, and throughout his career his strength was derived from the public confidence. In his colleagues Pitt appeared to prefer industry to genius. If this was partly because of an exaggerated sense of his own authority, it must also be remembered that the choice was also one of necessity. Pitt did overshadow his colleagues—but it was no difficult task. The result contributed to his general theory that the independence of Government departments was impossible. They must rather be bound together with a corporate policy, responsible to the Crown under a common allegiance to the prime minister. Walpole, who is generally considered the first prime minister, denied the title, and was succeeded by Governments which could only exist under the leadership of duumvirates and triumvirates. Pitt not only claimed the title of prime minister but declared that the office was essential to sane government. In 1803, when negotiations were on foot for a ministry in which the authority should be shared by himself and Addington, he stated that it was "an absolute necessity that there should be an avowed and real minister, possessing the Chief Weight in the Council and the principal place in the confidence of the King; in that respect there can be no rivalry or division of power. It must rest in the person generally called *first minister,* who ought to be at the head of the finances." And if a difference of opinion arose "the sentiments of the minister must be understood to prevail." This view moreover was widely understood by contemporary commentators. In 1794 when Lord Fitzwilliam went to Ireland he was pledged to support the Government "considering Mr. Pitt as the *Prime Minister* without whom no material measure as to *Things* or *persons* is to be concerted or done" (*Carlisle Papers*); and the Glenbervie Diary (Dec. 30, 1798) corroborates this language. In everything Pitt laboured to assert the authority of the cabinet, and of the premier within the cabinet. He was the king's

minister; but not the minister of the king's policy. The theory was thrashed out over small details. Pitt claimed, for instance, that the Crown must follow his recommendations in the nominations of bishops, and when the king refused to concur declared that he would take it as a decisive mark of lack of confidence.

Cold, aloof, and sarcastic, supporting a reputation for an almost tiresome integrity, Pitt was not popular except, at a distance, with the people, who saw him as an inspired leader, or with his few intimates, who found him secretly gentle and affectionate. In perspective he has become a man of no little mystery and of unexpected inconsistencies. There seems no good enough reason adequately to explain his changed attitude towards Reform; his treatment of the Reform agitators; his cold indifference to social suffering in England; his support of the Addington ministry in spite of his patent disapproval of its conduct; the lack of a firmer policy during the Fitzwilliam fiasco in Ireland. He remains a statesman: indisputably supreme in debate and tactics and tireless in organization. Because of the failure of the allied cause in the war, it was once popular to assume that Pitt neglected the army and navy, depending solely upon his efforts as an international financier. The assumption is entirely unfair. British naval prestige was at a low ebb at the end of the American war, and it was largely owing to Pitt's interest and to his generous allocations of money that the administration was reformed, and the mastery of the sea re-captured. When Pitt entered office English credit was debased: restoration was effected by his regenerated understanding of finance. In 1783 England was practically outside the concert of Europe, yet in a few years she had become the director of an almost united European policy. A true perception of the future of the Empire was not to come before the 19th century. Yet Pitt's colonial interests were remarkably wide—covering not only the great administrative acts for India and Canada but also the colonization of Australia; the fortification of the West Indies; the defence of Nootka Sound. African settlements were considered, and the territories annexed during the war selected with remarkable discretion.

Actually and theoretically Pitt bridged the distance between the 18th and 19th centuries. He was the source of the emancipation of trade and finance from antiquated restrictions. He was the origin of modern financial theory. Yet, though he warmly supported the abolition of the slave trade, he did nothing to improve the condition of the worker, nothing to promote social emancipation at home. That is perhaps the measure of his position in history. He is revered but not loved.

Pitt was never married. He once professed a tender inclination towards the daughter of Lord Auckland; but the embarrassment of his debts prevented him from a formal declaration of his feelings. His real passion was for his work; and to that he gave his life.

Bibliography.—The article in the Dictionary of National Biography contains a full bibliography. *See especially* Lord Rosebery's *William Pitt* and the works of Prof. J. H. Rose: *William Pitt and National Revival*, and *William Pitt and the Great War* (also published in one volume *Life of William Pitt*); *Pitt and Napoleon;* and *A Short Life of William Pitt.* (V. C. C.-B.)

PITTA, a genus of birds remarkable for their great beauty of coloration. For a long while the pittas were commonly supposed to be allied to the *Turdidae*, but they form a separate family, *Pittidae* of the Passeres. There are about 50 species, divided into a number of genera, confined to the Old World, and ranging from India and North China to Australia, New Guinea and New Britain, with one species in West Africa, the greatest number being found in Borneo and Sumatra. Pittas vary in size from that of a jay to that of a lark, and have a strong bill, a thick-set form, which is mounted on rather high legs with scutellated "tarsi," and a very short tail. In many of the forms there is little external difference between the sexes.

PITTACUS, of Mytilene in Lesbos (650?–570 B.C.), one of the Seven Sages of Greece. About 611, with the assistance of the brothers of the poet Alcaeus, he overthrew Melanchrus, tyrant of Lesbos. In a war (606) between the Mytilenaeans and Athenians for the possession of Sigeum on the Hellespont he slew the Athenian commander Phrynon in single combat. In 589 his fellow citizens entrusted Pittacus with despotic power (with the title of Aesymnetes) for the purpose of protecting them against the exiled nobles. He resigned the government after holding it for ten years. According to Diogenes Laërtius, who credits him with an undoubtedly spurious letter to Croesus, Pittacus was a writer of elegiac poems, from which he quotes five lines.

See Herodotus v. 27, 94; Diog. Laët. i. 4; Lucian, *Macrobii*, 18; Strabo xiii. 600, 617–618; Aristotle, *Politics*, ii. 12, iii. 14; T. Bergk, *Poetae lyrici graeci.*

PITTOSPORUM, in botany, the most numerous genus of the family Pittosporaceae, comprising about 100 species of evergreen trees and shrubs, native to tropical regions of the Old World, chiefly in the Southern Hemisphere. Many species are grown as ornamentals in warm regions, as in Florida and California, and as house or greenhouse plants in cooler latitudes. *P. Tobira* (Japanese pittosporum) and *P. viridiflorum* (Cape pittosporum) are attractive winter-blooming shrubs; *P. rhombifolium* (Queensland pittosporum) is often planted for avenues; *P. undulatum* (Victorian box), of Australia, is suitable for pruned hedges; *P. eugenioides* (tarata), of New Zealand, is useful in shrubberies; and *P. crassifolium* (karo) is planted for seaside windbreaks.

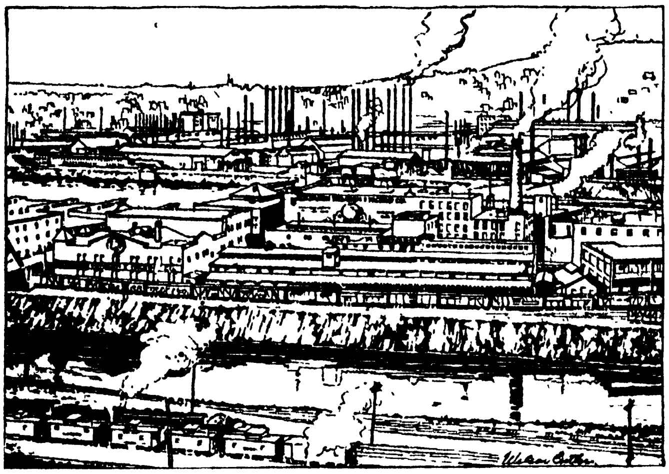
PITT-RIVERS, AUGUSTUS HENRY LANE-FOX (1827–1900), English soldier and archaeologist, son of W. A. Lane-Fox, was born on April 14, 1827. He entered the army, served in the Crimean War, and was one of the founders of the Hythe School of Musketry. General Pitt-Rivers made a collection of weapons and other things which was presented in 1883 to the University of Oxford. When, in 1880, General Pitt-Rivers obtained possession of his great-uncle's estates—practically untouched by the excavator since they had been the battleground of the West Saxons, the Romans and the Britons—he devoted himself to exploring them. His excavations round Rushmore resulted in valuable "finds"; he founded a local museum and published several illustrated volumes. As a scientific archaeologist he attained high rank. He received various honours, including the F.R.S. He married, in 1853, Alice Margaret, daughter of the second Lord Stanley of Alderley, and was the father of a large family; his second daughter became in 1884 the wife of Sir John Lubbock (Lord Avebury). He died at Rushmore on May 4, 1900.

PITTSBURG, a city of Contra Costa county, California. It is served by the Santa Fé, the Southern Pacific, the Western Pacific and electric railways and by steamship lines. Pop. 4,715 (1920), 35% foreign-born white; estimated locally at 14,000 in 1928. It has fisheries, salmon and fruit canneries, bean dryers, the largest steel works west of Chicago, ship-yards, planing mills and asbestos, rubber, cigar and chemical factories. It was founded in 1835. Coal was discovered in 1863, and the town was incorporated under the name of Black Diamond. In 1911 it was chartered as a city and the present name was adopted because of its industrial development and prospects. Since 1918 it has had a city-manager form of government.

PITTSBURG, a city of Crawford county, Kansas, U.S.A., on Federal highway 73E, near the south-east corner of the State It is served by the Frisco, the Kansas City Southern, the Missouri Pacific, the Santa Fe, and electric railways. Pop. 18,052 in 1920 (92% native white); 22,000 in 1928. It is in a great bituminous coal-field, where 3,000,000 tons or more are mined annually, and is near oil and gas-fields and the lead and zinc region of Kansas and Missouri. The main shops of the Kansas City Southern railway are here, and there are iron foundries, large brick and sewer tile works, and other manufacturing industries, with an aggregate output in 1925 valued at $4,632,914. Bank clearings for 1926 amounted to $78,800,000. The Kansas State Teachers college of Pittsburg (established 1903) has an annual enrolment of over 5,000. The city was settled about 1879 and chartered in 1880, when the population was 624. Between 1880 and 1890 it increased more than tenfold.

PITTSBURGH (sometimes, but erroneously, spelled Pittsburg), the second largest city of Pennsylvania, U.S.A., and the county seat of Allegheny county, on the Allegheny, Monongahela

and Ohio rivers, 440m. by rail, W. by S. of New York city, 348.5m. W. by N. of Philadelphia, 368m. N.W. of Washington and 468m. E. by S. of Chicago. Pop. (1910, after annexation of Allegheny) 533,905, and (1920) 588,343, increased (1927 U.S. census est.) to 665,500. In previous census years, the population was as follows: (1800), 1,565; (1820), 7,248; (1840), 21,115; (1860), 49,221; (1880), 156,389; (1890), 238,617; (1900), 321,616. After the 1920 census was taken, and up to 1927, parts of Chartiers, Reserve and Lower St. Clair townships, Frick Woods and St. Clair, Carrick, Knoxville and Westwood boroughs, with a population of 30,000 were annexed. Area 31,474·43ac. or 49·179 square miles. The chief business area, called the golden triangle, covers 974·3ac. or 1·52 square miles. Population within 10m. radius, 659·44 sq.m. (1920), 1,207,504, and of Allegheny county (1920), 1,184,832. As a city Pittsburgh ranks ninth and as a metropolitan fifth, in the United States. The sesquicentennial anniversary (1758–1908) of the city was elaborately observed in 1908.



THE CARNEGIE STEEL WORKS, ONE OF THE MANY STEEL PLANTS IN PITTSBURGH; SEEN FROM TROY HALL, ON THE NORTH SIDE

In the city, illiteracy is 4·8% compared with State average 4·6% but the illiteracy of native white is 0·3 compared with State average 0·8. The negro population was (1920) 6·4% or 37,725. Orientals are few. Of the 120,266 (1920) foreign born, 7,374 were natives of England, 2,758 of Scotland, 13,989 of Ireland, 1,512 of Wales, 1,049 of Sweden, 16,028 of Germany, 15,531 of Poland, 13,837 of Russia, 10,072 of Austria, 4,323 of Hungary, 3,607 of Czechoslovakia, 3,784 of Yugoslavia, 2,242 of Lithuania, 15,371 of Italy, 1,489 of Canada and 7,294 miscellaneous. Pittsburgh is served by the Pennsylvania, the Baltimore and Ohio, the New York Central (Pittsburgh and Lake Erie), the Buffalo, Rochester and Pittsburgh, the Bessemer and Lake Erie, and the Pittsburgh and West Virginia railways, and by boats on the Ohio, Monongahela and Allegheny rivers.

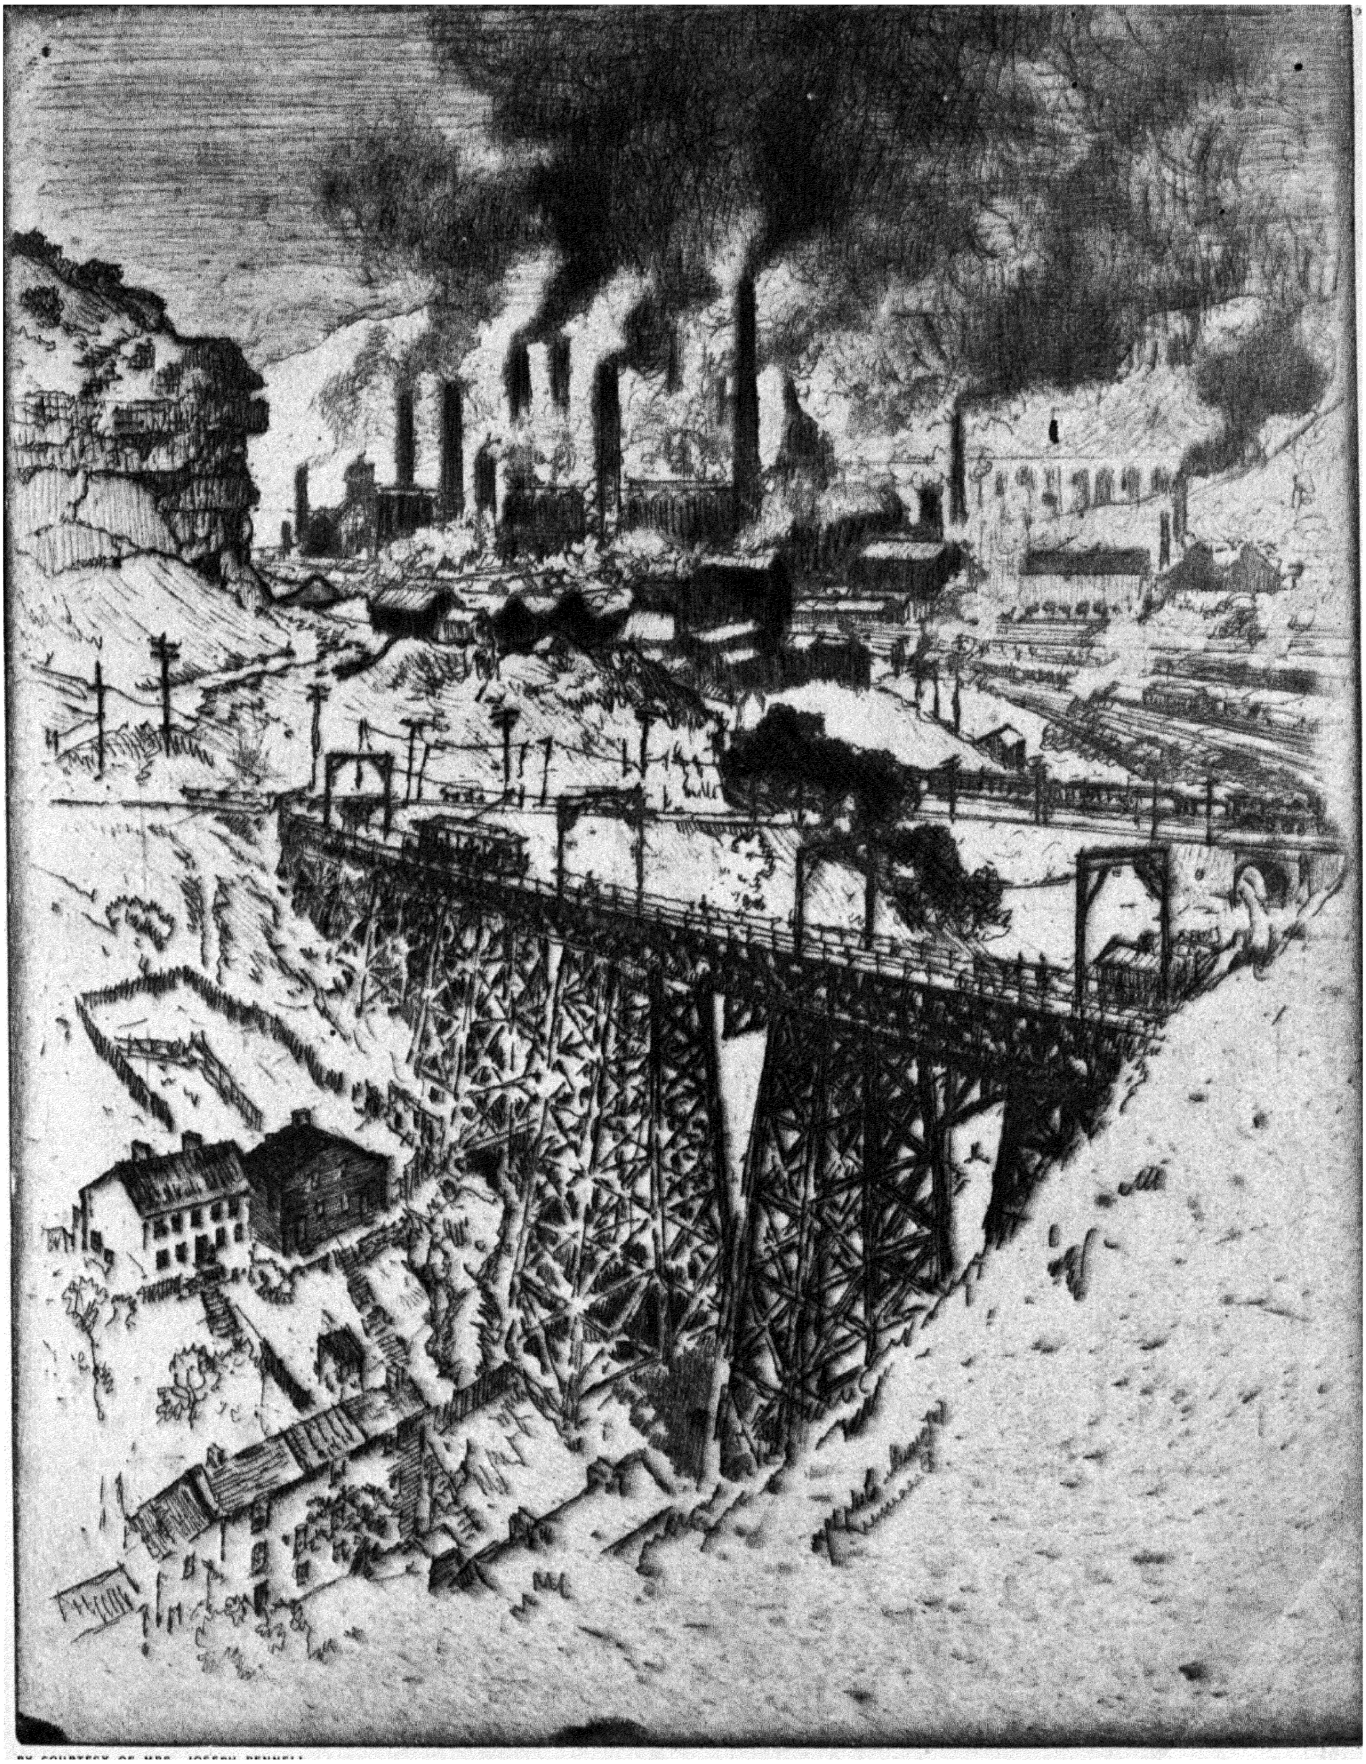
Picturesque rolling plateaux, the three rivers and narrow valleys from which rise high hills or precipitous bluffs, are the principal natural features of the district over which the city extends. Retail houses, wholesale houses, banks, tall office buildings, hotels, theatres and railway terminals are crowded into the angle, or "The Point," formed at the confluence of the Allegheny and Monongahela rivers, with Fifth avenue as the principal thoroughfare, especially for the retail houses, and Fourth avenue as the great banking thoroughfare. Factories extend for several miles along the banks of all three rivers into the tributary valleys, and are the cause of Pittsburgh's former nickname, "The Smoky City." With the practical elimination of smoke through the use of natural gas, a more recent nickname is the "Steel City" or "Electric City." The more attractive residential districts are on the plateau in the eastern portion of the district between the Allegheny and Monongahela rivers and on the undulating hills overlooking the Allegheny river from the north. Overlooking the Monongahela river is Schenley park (about 422ac.), the first city park, of which about 400ac. were given to the city in 1890 by Mrs. Mary E. Schenley. About 2m. to the north, overlooking the Allegheny river, is Highland park (about 366ac.), which contains the city reservoirs and a picturesque lake. Not far from Schenley park are Homewood and Calvary cemeteries; and the Frick woods (21ac.) donated for a park by the late Henry C. Frick; and not far from Highland park is Allegheny cemetery, also overlooking the Allegheny river. Across the Allegheny river, in the Allegheny district, are the beautiful Riverview park (240 ac.) in which is the Allegheny observatory, and West park (about 100 acres). In 1927 the county acquired the North and South parks (each 1,200ac.). Sixteen bridges span the rivers. The county in 1923 completed twin tunnels—each tube 25ft. wide and 5,889ft. long—at a cost of $6,000,000 under Mt. Washington to connect the southern hill with the city by a high-level bridge over the Monongahela.

Public Buildings and Institutions.—The city has some fine public buildings, office buildings and churches. The Allegheny county court house (1884–88) is one of H. H. Richardson's masterpieces. The Nixon theatre is also notable architecturally. The high Frick office building has exterior walls of white granite; in its main hall is a stained-glass window by John La Farge representing Fortune and her wheel. A large Government building of polished granite contains the post office and the customs offices. Other notable buildings are the City-County, Union Trust, Chamber of Commerce and a dozen others, equally imposing, together with several new hotels. St. Paul's cathedral (Roman Catholic, 1903–6) is largely of Indiana limestone. The city is the see of a Roman Catholic and a Protestant Episcopal bishop, and the residence of a bishop of the Methodist Episcopal Church. Other fine churches are Calvary, Sacred Heart, First Baptist and First Presbyterian. At the entrance to Schenley park, a great civic, educational, art and social centre is in process of development, including the University of Pittsburgh, Carnegie Institute and School of Technology, the Twentieth Century, University, Athletic, Knights of Columbus, Y.M.H.A. clubs, Soldiers' and Sailors' Memorial Hall, Masonic Temple, Syria Mosque, Armory, Schenley hotel, Forbes field (1903) and University stadium and, under construction in 1928, the 31-storey Cathedral of Learning.

In Schenley park is the Carnegie Institute (established by a gift of $10,000,000 from Andrew Carnegie, who made further contributions for its maintenance, its endowment in 1927 being $7,300,000 and that of the school $15,346,000 with provision for an addition to the latter of $12,000,000 by 1946) with a main building containing a library, a department of fine arts, a museum and a music hall, and separate buildings for the School of Technology which had (1927) 335 teachers and 6,716 students. The main building, dedicated in April 1907, is 600ft. long and 400ft. wide; in its great entrance hall is a series of mural decorations by John White Alexander, a native of the city. The library, in which the institution had its beginning in 1895, contained (1927) 630,629 volumes and has nine branches. The art department maintains the only international exhibition of modern paintings in the United States. The Phipps conservatory was presented to the city in 1903 by Henry Phipps (b. 1839), a steel manufacturer associated with Andrew Carnegie. It is the largest in America, and, with its Hall of Botany, which is utilized in instructing school children in botany, is situated in Schenley park. There is a zoological garden in Highland park.

In December 1907 it was decided that the several departments of the Western University of Pennsylvania, then situated in different parts of the city, should be brought together on a new campus of 43ac., increased to 77ac. (1927), near the Carnegie Institute. In July 1908 the name was changed to The University of Pittsburgh, in which are (1927) 824 professors and 10,207 students. The institution had its beginning in the Pittsburgh academy, which was opened perhaps as early as 1780 and was incorporated in 1787. It was incorporated as the Western University of Pennsylvania in 1819.

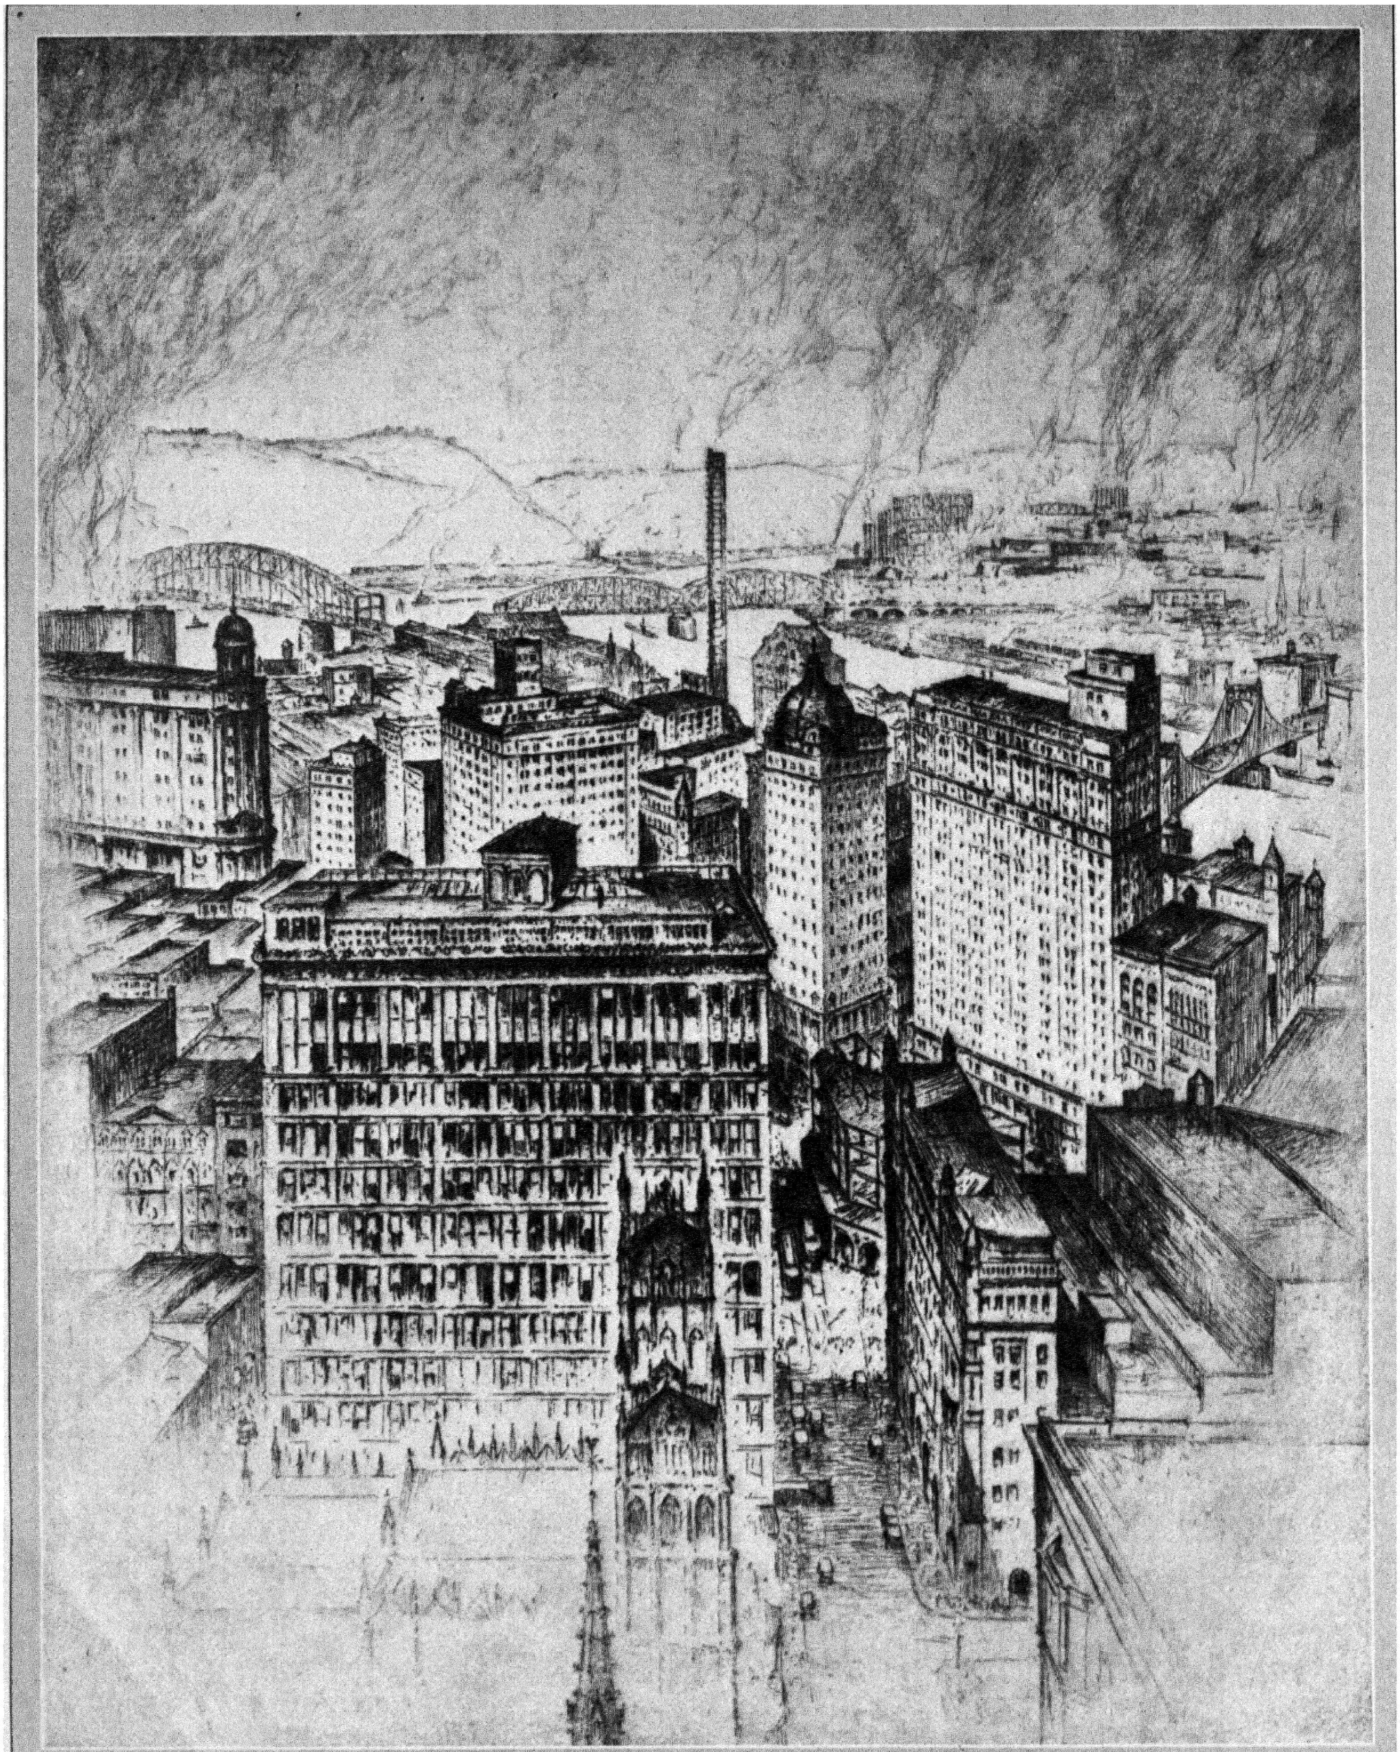
The Pennsylvania College for Women (Presbyterian; chartered in 1869), has collegiate and musical departments, and in 1927 had 39 teachers and 348 students. Overlooking the golden triangle is Duquesne university (Roman Catholic) with its schools of liberal arts, commerce, pharmacy and law and its 104



BY COURTESY OF MRS. JOSEPH PENNELL

AN ETCHING BY JOSEPH PENNELL OF STEEL WORKS IN PITTSBURGH

"Edgar Thomson's Steel Works," one of Pennell's etchings of scenes in the Pittsburgh steel manufacturing district



THE PITTSBURGH BUSINESS SECTION

A view of Pittsburgh, from an etching by Anton Schutz, looking toward the Monongahela and Allegheny rivers, which here join to form the Ohio river

teachers and 6,716 students (1927). In the Allegheny district are the Allegheny Theological seminary (United Presbyterian, 1825), the Western Theological seminary (Presbyterian, opened 1827), and the Reformed Presbyterian Theological seminary (1856). Under the new school code (1911) a board of education consisting of 15 members appointed by the judges of the common pleas courts controls the public schools. There were (1927) 17 high schools, with 979 teachers and 22,727 pupils, one Teachers' Training school, six special schools, 136 elementary schools, with 2,022 teachers and 79,122 pupils and evening schools with 12,224 pupils. The parochial schools had 11 high schools, 84 teachers and 2,837 pupils and 78 grade schools, 817 teachers and 38,254 pupils; and there are many private schools and academies, among them Shadyside academy. The Henry C. Frick Education Commission has an endowment of several millions for the improvement of teaching in the public schools.

The *Pittsburgh Gazette* (1786) was probably the oldest newspaper west of the Allegheny mountains and was (1906) consolidated with the *Times* (1879) under the name of *Gazette-Times* and recently (1927) consolidated with the *Post* (Sunday, 1792; daily, 1842) under the name *Post-Gazette,* the only morning paper. The evening papers are *Sun-Telegraph* and the *Pittsburgh Press* which purchased and discontinued (1923) the *Dispatch* (1846) and the *Leader* (Sunday 1864, daily 1870). A German and a Polish daily, weeklies in Slovak, Italian and other languages, and iron, steel, building, coal, glass, agriculture and other trade journals are published in the city. In Pittsburgh are published the *Presbyterian Banner* (1814, the second oldest religious paper in the United States), the *United Presbyterian,* the *Christian Advocate,* the *Catholic Observer,* the *Pittsburgh Catholic* and other weeklies.

The oldest hospital was the Reineman (1893), for maternity cases, made the University maternity hospital (1893) and transferred to Magee hospital (1910), the latter with the Children's, Eye and Ear and Presbyterian forming the new medical Centre of the University of Pittsburgh Other hospitals are: Municipal (1878), Tuberculosis, Homeopathic, Montefiore, Passavant, Roselia Maternity, St. Johns, St. Josephs, St. Margaret Memorial, South Side, West Penn, Allegheny General, Columbia, in charge of United Presbyterian Women's Association, and the Sisters of Mercy, Mercy hospital, Sisters of St. Francis, St. Francis hospital, and the Sisters of Charity, Pittsburgh hospital. The Western Pennsylvania schools for the deaf and for the blind, are located in Pittsburgh and many of the hospitals, schools, homes and charitable institutions, non-sectarian, are in part maintained by the State. The Y.M.C.A. had 14 branches and the Y.W.C A. (metropolitan) had six branches (1927), and there were 556 churches, 20 all-year playgrounds, 14 public swimming pools, 28 parks and over 200 social and welfare agencies.

Industry and Commerce.—Pittsburgh is in the midst of the most productive coal-fields in the country; the region is also rich in petroleum and natural gas. The city is on one of the main lines of communication between the east and the west, is the centre of a vast railway system, and has freight yards in and outside the city with a total capacity for more than 60,000 cars. Its harbour has a total length on the three rivers of 27·2m., and an average width of about 1,000ft., and has been deepened by the construction (in 1877–85) of the Davis Island dam, by dredging, under a Federal project of 1899. This dam has been superseded by the Emsworth fixed dam. Slack water navigation has been secured on the Allegheny by locks and dams (1890, 1896 *et seq.*) at an expense up to July 1909 of $1,658,804; and up to that time $263,625 had been spent for open-channel work. In 1927–28 three new dams, Nos. 4, 5 and 6 were completed. The Monongahela from Pittsburgh to the West Virginia State line (91·5m.) was improved in 1836 *et seq.*, by a private company which built seven locks and dams; this property was condemned and bought for $3,761,615 by the United States Government in 1897, and, under the project of 1899 for rebuilding three of the locks and enlarging another, and that of 1907 for a new lock and dam and for other improvements, $2,675,692 was spent up to July 1909. Since then six of these have been entirely rebuilt and changed to two chamber locks and instead of no. 7 two new and larger locks have been constructed. Coal is brought to the city from the coal-fields by boats on the Allegheny and Monongahela rivers as well as by rail, and great fleets of barges carry coal and other heavy freight, such as steel rails, cotton ties, sheet iron, wire and nails, down the Ohio in the winter and spring. A ship canal to provide water communication between Pittsburgh and Lake Erie has been projected and is awaiting the approval of the army engineers. The railways have a heavy tonnage of coal, coke and iron and steel products, and a large portion of the iron ore that is produced in the Lake Superior region is brought to Pittsburgh. In 1926 the river traffic amounted to 30,717,002 tons and in 1925 it was 35,458,669, much of which was carried on barges down the Ohio. Pittsburgh is also a port of entry; in 1927 the value of its imports amounted to $9,181,226.

The value of factory and mine products (1926) including 11 industries and 2,316 establishments, was $2,976,503,400, and the by-products, $1,079,650,000. In the manufacture of iron and steel products Pittsburgh ranks first among the cities of the United States, the value of these products amounting in 1926 to $1,295,911,100 with by-products amounting to $514,096,800. The amount of salaries and wages paid was $343,111,000 and the capital invested was $1,129,587,600 In the World War Pittsburgh made 58% of war munitions. Pittsburgh was first in iron, steel, glass, electrical machinery, steel cars, tin plate, air brakes, fire-brick, white lead, food preserving, corks, aluminium, railway signals and safety devices, vanadium, bituminous coal and coke, furnishing 25% of the nation's steel, 10% of steel rails, 47% of pipe and tubing, 20% of pig iron, 20% of plate and window glass, 40% of bituminous coal, 33% of by-product coke and 86% of beehive coke. Pittsburgh occupies with San Francisco and Los Angeles fifth place in bank clearings and (Oct. 1927) had national bank deposits $459,667,442, State bank deposits $153,399,522 and trust and savings deposits $351,256,793. In Pittsburgh or the immediate vicinity are the more important plants of the United States Steel corporation, including that of the Carnegie company, and the Jones and Laughlin Steel corporation, one of the largest independent steel companies in the United States. Here, too, are the plants of the Westinghouse company for the manufacture of electrical apparatus, of air-brakes invented by George Westinghouse (born 1846), and of devices for railway signals which he also invented. In the Allegheny district the H. J. Heinz company with its 57 varieties has its main food-preserving plant, the largest establishment of the kind in the country.

Government.—The Pittsburgh charter of 1816 vested the more important powers of the city government in a common council of 15 members and a select council of nine members, and until 1834 the mayor was appointed annually by these city councils from their own number. By the Wallace Act of the State legislature in 1874 a form of government was provided for cities of three classes, and Pittsburgh became a city of the second class (population between 100,000 and 300,000); under the Act of 1895 a new classification was made, under which Pittsburgh remains in the second class. An Act of 1887 had amended the provisions of the Wallace Act in regard to second class cities by changing the terms of select councilmen from two to four years and of common councilmen from one to two years. In 1901 a new act was passed for the government of cities of the second class. It provided that the executive be a "city recorder"; this provision was repealed in 1903, when the title of mayor again came into use. By act of legislature (1911) the former common and select councils were superseded by a small council of nine members, elected by general vote of the entire city. The mayor, elected by the people for a term of two years, continued to appoint the heads of departments (public safety, public works, assessors, treasurer, law, welfare, health and supplies), and the comptroller also continued to be elected by popular vote. By a two-thirds vote the council may pass resolutions or ordinances over the mayor's veto. The department of public safety controls the bureaux of police, fire, building inspection, electricity and general office; the department of public works controls the bureaux of water, highway and sewers, property, parks, recrea-

tions, tests, lights, deed registry, bridges and construction. The mayor appoints the members of the civil service commission. Through a city-planning commission, recommending zoning ordinances and through a board of adjustment, the height and character of all buildings are controlled. A bureau of traffic relief and a traffic commission were created in 1924, and in 1925 a department of city transit, charged with the regulation of traffic conditions and with the matter of recommending subways and a comprehensive system of rapid-transit lines for the entire city. In 1927 the taxable valuation was $344,625,560 for land and buildings and the tax rate was 22·40 mills on land, 11·20 on buildings and 11·50 for schools. The water supply of Pittsburgh is taken from the Allegheny river and pumped into reservoirs, the highest of which, in Highland park, is 367ft. above the river; and there is a slow sand filtration plant for the filtration of the entire supply. (S. B. McC.)

PITTSFIELD, a city of western Massachusetts, U.S.A., the county seat of Berkshire county; on Federal highways 7 and 20, and served by the Boston and Albany and the New York, New Haven and Hartford railways. Pop. (1920) 41,763 (20% foreign-born white); 1928 local estimate 50,000. It occupies 41·4 sq.m., at an altitude of 1,000 ft., in the midst of the Berkshire hills. Three branches of the Housatonic river wind through the city, uniting about a mile from the central green. Within its limits are the villages of Barkerville, Coltsville Junction, Pontoosuc, Shaker, Stearnsville, Taconic, Tillotsons and West Pittsfield, and the whole or parts of five lakes (Pontoosuc, Onota, Morewood, Silver and Richmond). It is a well built city, with dignified public buildings, substantial business blocks, modern schools, shaded residential streets and on the outskirts large manufacturing plants. The assessed valuation for 1927 was $57,809,775. Pittsfield is a touring centre and a resort for winter sports. Its manufacturing industries are large and distinctive, with an output in 1925 valued at $51,880,490. They include a plant of the General Electric Company, making monster transformers and other machinery and devices, where artificial lightning was produced in 1927; and the mill that makes all the paper used for the U.S. bank notes and Government bonds. The oldest industry (still one of the most important) is textile manufacturing, chiefly woollen goods. Fine stationery, paper-mill equipment, machine tools, spool silks and silk braids are other leading products. The first settlement within the present boundaries of Pittsfield (Boston Plantation or Pontoosuc), made in 1743, was soon abandoned because of trouble with the Indians. It was revived in 1749, and in 1761 was incorporated as the town of Pittsfield, named in honour of the elder William Pitt. The town was chartered as a city in 1889. Shaker Village was settled (by Shakers) about 1790. Elkanah Watson (1758–1842), while living (1807–16) at what is now the Country club, introduced the merino sheep.

PITTSTON, a city of Luzerne county, Pennsylvania, U.S.A., on the Susquehanna river just below the mouth of the Lackawanna, about midway between Scranton and Wilkes-Barre. It is served by the Central of New Jersey, the Delaware and Hudson, the Erie, the Lackawanna, the Lackawanna and Wyoming Valley and the Lehigh Valley railways. Pop. (1920) 18,497 (26% foreign-born white, about half from Italy), and 6,968 in the adjoining borough of West Pittston (87% native white). Within 2·5 m. of the city hall about 60,000 persons were living in 1928. Pittston is in the midst of the anthracite coal region. Fire-clay also abounds. The city has paper, silk and knitting mills, terra-cotta works, brass foundries, cigar and cut-glass factories, and the Lehigh Valley railroad employs 1,200 men. It was one of the five towns founded in the Wyoming valley by the Susquehanna company of Connecticut, and was named after the elder Pitt. It was settled about 1770, incorporated as a borough in 1803 and chartered as a city in 1894.

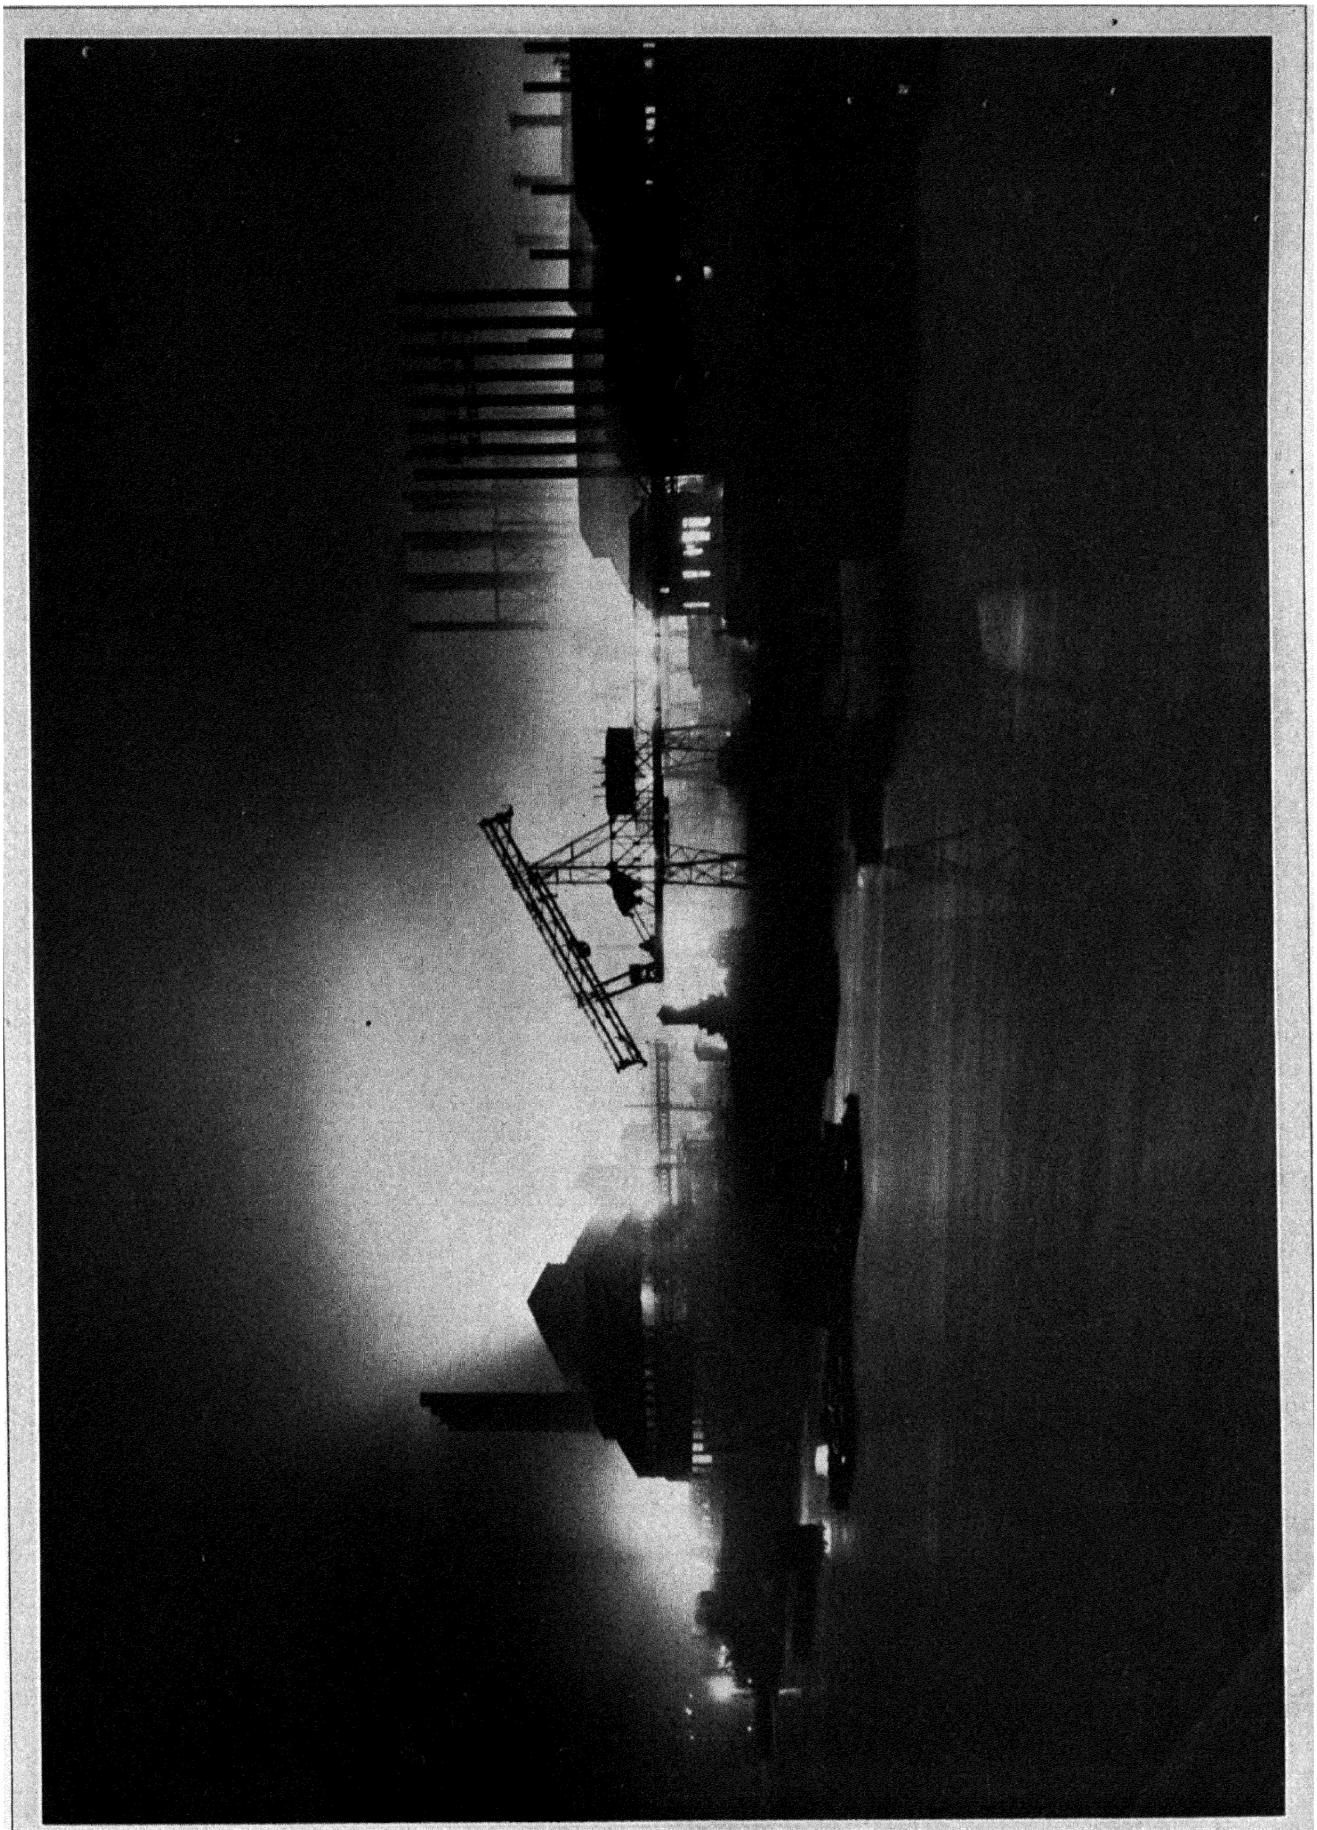
PITUITARY EXTRACT or **PITUITRIN:** *see* ANIMAL EXTRACTS.

PITYRIASIS VERSICOLOR, a skin disease, consisting of patches of brown discoloration, mostly on the front of the body, and often attended with itching, especially after exercise. The epidermis is scaly over the patch, and among the *débris* there may be seen minute oval spores of a vegetable parasite, the *Microsporon furfur*. The disease is mostly one of adults, found all over the world, and not associated in any special way with poor general health. The treatment consists of rubbing in an ointment of potassium sulphide or one of the mercurial ointments, or using sulphur-soap habitually.

PIURA, a coast department of northern Peru, with area 15,239 sq.m.; pop. (est. 1920) 213,909. The department includes mountainous areas in the north (Cerros de Amatope) and east (cordilleran *sierra*) and a great desert (Sechura) in the south. The chief rivers are the Chira, a permanent stream, and the Piura. Crops are grown with the aid of irrigation as there is rainfall only at intervals of years. Cotton-growing is the leading industry in the irrigated valleys, stock-raising in the *sierra*. The cultivation of *aspero* (full-rough cotton) is peculiar to this department, the product of a large bush, and is known as vegetable wool (*see* PERU: *Agriculture*). There are gins and factories for making cotton-seed oil and cake; also a crushing-mill for castor-beans which produces about 20,000 gal. of castor-oil annually. Other crops include rice, sugar, tobacco, maize, potatoes, yuca, beans, cacao and fruits, all of which are consumed locally. *Sierran* cattle are fattened in the upper valleys. Goats are raised extensively. Charcoal is made from the wood of the algaroba tree. Though mineral deposits are widespread, petroleum is the only one exploited. It now heads the list of Peruvian exports and the only producing oil fields in the republic are in the department of Piura and the adjoining province of Tumbez. They lie along the north-western coast, a narrow belt about 60 m. in length. The two chief operating companies are in Piura; the International Petroleum Corporation, a subsidiary of the Standard Oil Company, whose chief field is Negritos, 40 m. north-west of Paita, produces about 80% of the national output (1,140,000 tons in 1926) and has a modern refinery at its port, Talara. The Lobitos Oil Company, 10 m. north of Talara, formerly British, now Peruvian, produced 271,000 tons in 1926, shipped *via* Talara to the United States and Canada for refining. About 15% of total production is consumed in Peru, largely as crude oil by railways. A standard gauge railway runs from Paita (*q.v.*), to Piura (58 m.) by way of Sullana, a distributing centre for southern Ecuador, and narrow gauge railways connect the oil-fields with Talara. Roads are under active construction and sections of the coast highway and of the road across the Andes from Paita to the Amazon are finished. Piura, capital of the department, pop. (estimated 1920) 15,000, is on the Piura river, 164 ft. above sea-level. It was founded by Pizarro in 1532 on a slightly different site. It has electric lights, telephone and telegraph, banks, theatres, superior court, secondary schools and an excellent hospital. Catacaos, 6 m. south of the capital, is the centre of the Panama hat industry. Hats are woven from leaves of *toquilla* palm (*Carludovica palmata*).

PIUS I., pope from about 141 to 154. He was the brother of Hermas, author of the *Shepherd*.

PIUS II. (Enea Silvio de Piccolomini, known in literature as Aeneas Silvius), pope from 1458 to 1464, was born on Oct. 18, 1405, at Corsignano (later called Pienza after him) near Siena. His family claimed to trace descent from Romulus. The eldest of 18 children, he worked on the farm with his father until a priest enabled him, at the age of 18, to go as a poor student to Siena, where he divided his time between severe humanistic studies and sensual pleasure. He was attracted to Florence by the teaching of Filelfo. He became secretary to Domenico Capranica, bishop of Fermo, and went with him to the Council of Basle, where he stayed several years (1431–35), changing masters whenever he could improve his position. He was engaged on various errands, some of them dangerous; they included a long journey to England and Scotland on secret diplomatic business. In 1436 he was back at Basle, and, although a layman, obtained a seat in the council and exercised considerable influence. Aeneas took an active part in the council after it was transferred to Florence, and though he still declined to take orders, he was given a position on the conciliar conclave which elected Amadeus of Savoy as pope under the title of Felix V. In return for his



VIEW OF PITTSBURGH STEEL MILLS AT NIGHT

PHOTOGRAPH, HINE FROM EWING GALLOWAY

services Felix made Aeneas papal secretary.

A new period of his career opened in 1442, when he was sent by the council to take part in the diet of Frankfurt-on-Main. Here he met Frederick III. of Germany, who made him poet laureate and his private secretary. He ingratiated himself with the chancellor, Kasper Schlick, at Vienna, one of whose adventures he celebrated in *Lucretia and Eurialus*, a novel in the style of Boccaccio. At this period he also wrote his witty but immoral play, *Chrisis*. In 1446 he took orders as subdeacon, and wrote that he meant to reform, "forsaking Venus for Bacchus." Aeneas was useful to Frederick as a diplomatist, and managed to give all parties the impression that he was the devoted advocate of each. He took an important part in the diet of Nuremburg (1444), and in 1445 made his peace with Eugenius. At the diet of Frankfurt (Sept. 1446) Aeneas modified the hostility of the electors to pope and emperor. The new pope, Nicholas V., made him bishop of Siena, and for his services in negotiating the concordat of Aschaffenburg in 1448 he was made prince of the empire and cardinal.

The death of Calixtus III. (who succeeded Nicholas V.) occurred on Aug. 5, 1458. After a hot fight in the conclave, Aeneas was elected and took the title Pius II., with a reminiscence of Virgil's "pius Aeneas." The humanists hailed his election with joy, and flocked around to secure a share of the good things, but they were bitterly disappointed, as Pius did not prove himself the liberal and undiscriminating patron they hoped. The fall of Constantinople in 1453 made a deep impression upon Pius, and he never ceased to preach the crusade against the Turk. In Sept. 1459 he opened a congress at Mantua to promote the crusade, but both the French and the Germans were annoyed with him for different reasons, and he received little support. He believed that the decline in the papal influence was due to the usurpation of power by the councils, and he now issued (Jan. 1460) the bull *Execrabilis et in pristinis temporibus inauditus*, in which he condemned as heretical the doctrine that the councils were superior to the popes, and proclaimed the anathema against any one who should dare to appeal to one.

While Pius was at Mantua war broke out between the French and Spanish in southern Italy, and a rising of the barons devastated the Campagna. Hurrying back to Rome, Pius succeeded in quelling the disorders. This measure still further alienated the pope from the French, with whom he was at that time negotiating for the abrogation of the Pragmatic Sanction. When Louis XI. came to the throne (Nov. 1461), he sent to Pius saying that he had abolished the Pragmatic Sanction, hoping in return to get the kingdom of Naples, for his countryman, René of Anjou. As Pius continued to support Ferdinand, Louis retaliated by reasserting the ancient liberties of the Gallican Church. At the same time a serious quarrel with the Germans prevented anything being done towards a crusade. George Podiebrad, king of Bohemia, was plotting to depose the emperor Frederick III., who was supported by Pius. Diether, archbishop of Mainz, took the side of Podiebrad, and replied to Pius's measures by appealing to a general council. He was declared deposed by the pope, but kept his seat, and in 1464 compelled the pope to recognize him again. The quarrel with Podiebrad, who was accused of supporting the Utraquist heresy, continued with increasing bitterness, but without any decisive result, until the death of Pius. In the meantime the pope did what he could to further the cause of the crusade. The discovery of alum mines at Tolfa gave him an unexpected pecuniary resource, and to stimulate the zeal of Christendom, Pius took the cross on June 18, 1464. He set out for Venice, where he intended to sail for the East, but he was attacked with a fever, and on Aug. 14, 1464, he died.

Pius II. was a voluminous author. Besides poems, a novel and a play, he wrote a number of orations, which were considered models of eloquence in their day. The tale of *Euryalus and Lucrezia* was translated into many languages (Eng., 1560), and his Latin poems, *Miseriae curialium* (Rome, 1473), were read throughout Europe. Alexander Barclay translated some of them in *Certayne Eglogues* . . . (1548?) repr. by Spenser Society (1885). His most valuable work, however, is his *Pii II. Commentarii rerum memorabilium quae temporibus suis contigerunt*, a history of his times, told in an interesting and rational manner. Also, there is the *Cosmographia in Asiae et Europae . . . descriptione*, of which a complete edition was published at Venice in 1503, and *Historia Bohemica* (Cologne, 1532).

Bibliography.—The letters of Pius II. are in process of publication by R. Wolkan, *Der Briefwechsel des Eneas Silvius Piccolomini* (Vienna, 1909–), in *Fontes rerum Austriacarum*. The *Commentaries* were published in 1584, as begun by Pius himself, and completed by J. Gobellinus. His other works are found in *Aenae Silvii opera omnia*, edit. M. Hopperus (Basle, 1551). *See* also Herzog-Hauck, *Real-encyklopädie* (1904), vol. xv., where a full bibliography will be found; Voigt, *Pius II.* (1856–63); L. Pastor, *History of the Popes from the Close of the Middle Ages* (Eng. trans., 1896, vol. ii.); M. Creighton, *History of the Papacy during the Reformation*, vol. ii. (1882); W. Boulting, *Aeneas Silvius* (1908); C. M. Ady, *Pius II.: the Humanist Pope* (1913); C. Lucius, *Pius II. und Ludwig XI. von Frankreich, 1461–62* (1913).

PIUS III. (Francesco Nanni-Todeschini-Piccolomini), pope from Sept. 22 to Oct. 18, 1503, was born at Siena on May 9, 1439. He was made archbishop of Siena and cardinal-deacon of St. Eustachio by his uncle Pius II. He was employed by subsequent popes in several important legations. He opposed the policy of Alexander VI., and succeeded him as pope through the interested influence of Cardinal della Rovere, afterwards Julius II.

The main importance of his pontificate lies in his reassembling of the Council of Trent, which Paul IV. had allowed to disband, considering its work completed. It was finally closed, after sessions lasting more than two years, in Dec. 1563, and the bull confirming its decrees was issued in Jan. 1564. Pius was a man of blameless life, and would doubtless have accomplished much had he lived. His successor was Julius II.

PIUS IV. (Giovanni Angelo Medici, or "Medighino"), pope from 1559 to 1565, was born at Milan on March 31, 1499. He began his career as a lawyer, but later entered the service of Paul III., who made him a cardinal in 1549. In the protracted conclave that followed the death of Paul IV. the election of Pius (Dec. 25, 1559) was due to a compromise between the Spanish and French. In temperament Pius was affable, vivacious, convivial. He was, moreover, astute, diplomatic and experienced in affairs. He allowed the reform movement initiated by Paul IV. free course, but tried to repair certain injustices of Paul IV., and mitigated some of his extreme decrees. But to the nephews of Paul he showed no mercy: they were charged with various crimes, condemned, upon testimony of suspicious validity, and executed on March 5, 1561. With England lost to the papacy, Germany overwhelmingly Protestant, and France on the verge of civil war, Pius realized how fatuous was the anti-Spanish policy of his predecessor. He therefore recognized Ferdinand as emperor, and conciliated Philip II. with extensive ecclesiastical privileges. But subsequently, antagonized by Philip's arrogance, he assisted France with troops and money for use against the Huguenots.

After a suspension of ten years the council of Trent reconvened on Jan. 18, 1562. Among the demands presented by the various nations were the recognition of the equality of the episcopate, communion in both kinds, clerical marriage and the use of the vernacular in Church services. It required all the pope's diplomacy to avoid compliance on the one hand, and a breach with the powers on the other. Thanks to Morone and Borromeo, however, he achieved his end. The council was dissolved on Dec. 4, 1563, and its decrees and definitions confirmed by the pope (Jan. 26, 1564), who reserved to himself the sole right of interpretation, and took various measures for enforcing its decisions.

After the termination of the council Pius indulged his desire for ease and pleasure, to the great offence of the rigorists. Pius fortified Rome, and contributed much to the embellishment of the city—among other works, the church of Sta. Maria degli Angeli in the Baths of Diocletian; the Porta Pia; the Villa Pia in the

Vatican Gardens; and the Palace of the Conservatori. He died on Dec. 9, 1565, and was succeeded by Pius V.

PIUS V. (Michele Ghislieri), pope from 1566 to 1572, was born on Jan. 17, 1504, in the Milanese. At the age of fourteen he became a Dominican monk. He was appointed inquisitor in Como, where his zeal provoked such opposition as to compel his recall (1550). The chief inquisitor, Caraffa, convinced of his value, straightway sent him upon a mission to Lombardy, and in 1551 appointed him commissary-general of the Holy Office. When Caraffa became pope, Ghislieri was made bishop of Nepi and Sutri, cardinal (1557), and finally grand inquisitor. In this office he was continued by Pius IV., whom, however, he antagonized by his censoriousness and obstinacy. But after the death of Pius IV., the rigorists, led by Borromeo, had no difficulty in making him pope (Jan. 7, 1566). Retaining his ascetic mode of life, Pius immediately began the work of reform. Decrees and ordinances were rapidly issued; the papal court became a model of sobriety; prostitutes were driven from the city, or confined to a certain quarter; penalties were attached to Sunday desecration, profanity and animal baiting; clerical residence was enforced; conventuals were compelled to live in strict seclusion according to their vows; catechetical instruction was enjoined. A new catechism appeared in 1566, followed by an improved breviary (1568), and an improved missal (1570). The use of indulgences and dispensations was restricted, and the penitential system reformed.

Pius was the avowed enemy of nepotism. One nephew, it is true, he made cardinal, but allowed him no influence: the rest of his relatives he kept at a distance. By the constitution *Admonet nos* (March 29, 1567), he forbade the reinvestiture of fiefs that should revert to the Holy See, and bound the cardinals by oath to observe it. In March 1569 Pius ordered the expulsion of the Jews from the States of the Church. For commercial reasons they were allowed to remain in Rome and Ancona, but only upon humiliating conditions. In February 1571, the Umiliati, a degenerate monastic order of Milan, was suppressed on account of an attempt upon the life of the archbishop, Carlo Borromeo.

The rules governing the Holy Office were sharpened; old charges, long suspended, were revived; rank offered no protection, but rather exposed its possessor to fiercer attack; none were pursued more relentlessly than the cultured, among whom many of the Protestant doctrines had found acceptance; princes and states withdrew their protection, and courted the favour of the Holy See by surrendering distinguished offenders. Cosimo de' Medici handed over Pietro Carnesecchi (and two years later received in reward the title of grand duke, Sept. 1569); Venice delivered Guido Zanetti; Philip II., Bartolomé de Carranza, the archbishop of Toledo. In March 1571 the Congregation of the Index was established, and hundreds of printers took flight to Switzerland and Germany. The regret of Pius was that he had sometimes been too lenient. He spurred Philip II. on in the Netherlands, and commanded the utter extermination (*ad internecionem usque*) of the Huguenots; he protested against the tolerance shown by the emperor. One of his cherished schemes was the dethronement of Elizabeth, whom he excommunicated and declared a usurper (Feb. 25, 1570); but he had to content himself with abetting plots and rebellions. He effected an alliance with Spain and Venice against the Turks, and contributed to the victory of Lepanto (Oct. 6, 1571). Pius died on May 1, 1572; and was canonized by Clement XI. in 1712.

See Ciaconius, *Vitae et res gestae summorum pontiff. rom.* (Rome, 1601–02; a contemporary of Pius); *Acta sanctorum, maij,* tom. i. pp. 616 *seq.*, containing the life by Gabuzio (1605), based upon an earlier one by Catena (1586); Falloux, *Hist. de St. Pie V.* (3rd ed., Paris, 1858), eulogistic; Mendham, *Life and Pontificate of St. Pius V.* (London, 1832), a bitter polemic. The life of Pius has also been written by Fuenmayor (Madrid, 1595), Paolo Alessandro Maffei (Rome, 1712), and by T. M. Granello (Bologna, 1877). His letters have been edited by Catena (*vide supra*), Goubau (Antwerp, 1640), and a select number in a French translation, by de Potter (Paris, 1826). *See* also Hilliger, *Die Wahl Pius V. zum Papste* (Leipzig, 1891); Ranke, *Popes* (Eng. trans., Austin), i. 361 *seq.*, 384 *seq.*; and von Reumont, *Gesch. der Stadt Rom.* iii. 2, 557 *seq.*

PIUS VI. (Giovanni Angelo Braschi), pope from 1775 to 1799, was born at Cesena, on Dec. 27, 1717. After taking the degree of doctor of laws he went to Ferrara and became the private secretary of Cardinal Ruffo, in whose bishopric of Ostia and Velletri he held the post of *uditore* until 1753. His skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV., who appointed him one of his secretaries and canon of St. Peter's. In 1758 he was raised to the prelature, and in 1766 to the treasurership of the apostolic chamber by Clement XIII., and in 1773 he became cardinal-priest of San Onofrio. In the four months' conclave which followed the death of Clement XIV., Spain, France and Portugal at length dropped their objection to Braschi, and he was elected to the vacant see on Feb. 15, 1775.

Pius had received the support of the ministers of the Crowns and the anti-Jesuit party upon a tacit understanding that he would continue the action of Clement, by whose brief *Dominus ac redemptor* (1773) the dissolution of the Society of Jesus had been pronounced. On the other hand the *zelanti*, who believed him secretly inclined towards Jesuitism, expected from him some reparation for the alleged wrongs of the previous reign. The half-measures adopted by Pius gave little satisfaction to either party. It is perhaps largely due to him that the order was able to escape shipwreck in White Russia and Silesia; in 1792 he considered its re-establishment as a bulwark against revolutionary ideas.

The authority of the papacy was threatened in Austria by the social and ecclesiastical reforms undertaken by Joseph II. and, in the hope of staying them, Pius adopted the exceptional course of visiting Vienna in person. His mission proved a fiasco; he was, however, able a few years later to curb those German archbishops who, in 1786 at the Congress at Ems, had shown a tendency towards independence. Difficulties also arose in Naples and in Tuscany. At the outbreak of the French Revolution Pius saw the old Gallican Church suppressed, the pontifical and ecclesiastical possessions in France confiscated and an effigy of himself burnt by the populace at the Palais Royal. The murder of the republican agent, Hugo Basseville, in the streets of Rome (January 1793) gave new ground of offence; the papal court was charged with complicity by the French Convention; and Pius threw in his lot with the league against France. In 1796 Napoleon invaded Italy, defeated the papal troops and occupied Ancona and Loreto. Pius sued for peace, which was granted at Tolentino on Feb. 19, 1797; but on Dec. 28 of that year, in a riot created by some Italian and French revolutionists, General Duphot of the French embassy was killed and a new pretext furnished for invasion. General Berthier marched to Rome, entered it unopposed on Feb. 13, 1798, and, proclaiming a republic, demanded of the pope the renunciation of his temporal authority. Upon his refusal he was taken prisoner, and on Feb. 20 was escorted from the Vatican to Siena, and thence to the Certosa near Florence. The French declaration of war against Tuscany led to his removal by way of Parma, Piacenza, Turin and Grenoble to the citadel of Valence, where he died six weeks later, on Aug. 29, 1799. Pius VII. succeeded him.

See Zöpffel and Benrath, "Pius VI.," in Herzog-Hauck, *Realencyklopädie*, 3rd ed., vol. xv., pp. 441–451 (Leipzig, 1904, with elaborate bibliography); F. Nielsen, *History of the Papacy in the 19th Century*, vol. i. chap. vii. (London, 1906); J. Gendry, *Pie VI. sa vie, son pontificat, d'après les archives vaticanes et de nombreux documents inédits* (2 vols., 1907).

PIUS VII. (Luigi Barnaba Chiaramonti), pope from 1800 to 1823, the son of Count Scipione Chiaramonti and the deeply religious Countess Ghini, was born at Cesena on Aug. 14, 1740 (not 1742). He entered the Benedictine monastery of St. Mary at Cesena, and held various teaching appointments in the colleges of his order at Parma and at Rome. He was created an abbot of his order by his relative Pius VI., who also appointed him bishop of Tivoli in 1782, and raised him to the cardinalate and the see of Imola in 1785. He became pope on March 14, 1800.

His attention was at once directed to the ecclesiastical anarchy of France, and he negotiated the celebrated concordat of 1801.

(*See* CONCORDAT.) The importance of this agreement was, however, considerably lessened by the "articles organiques" appended to it by the French government on April 8, 1802. In 1804 Napoleon opened negotiations to secure at the pope's hands his formal consecration as emperor. After some hesitation Pius was induced to perform the ceremony at Notre Dame and to extend his visit to Paris for four months; but in return for these favours he was able to obtain from Napoleon merely one or two minor concessions. Napoleon soon began to disregard the Italian concordat of 1803, and himself decreed the dissolution of the marriage of his brother Jerome with Miss Patterson of Baltimore. The irritation between France and the Vatican increased so rapidly that on Feb. 2, 1808 Rome was occupied by General Miollis; a month later the provinces of Ancona, Macerata, Fermo and Urbino were united to the kingdom of Italy, and diplomatic relations between Napoleon and Rome were broken off; finally, by a decree issued from Schönbrunn on May 17, 1809, the emperor united the Papal States to France. Pius retaliated by a bull excommunicating the invaders; and, to prevent insurrection, Miollis—either on his own responsibility, as Napoleon afterwards asserted, or by order of the latter—employed General Radet to take possession of the pope's person. On July 5 Pius was made prisoner; he was taken to Grenoble, and then to Savona, where he steadfastly refused canonical institution to the bishops nominated by Napoleon. In 1812 the aged and sick pontiff was removed to Fontainebleau, where he was lodged in a suite of regal magnificence to await the return of the emperor from Moscow. When Napoleon arrived, he entered into personal negotiations with the pope, who on Jan. 25, 1813 assented to a concordat so degrading that his conscience found no relief until, on the advice of the cardinal Pacca and Consalvi, he abrogated it (March 24); and on the 9th of May he defied the emperor by declaring invalid all the official acts of the new French bishops. Napoleon sent him back to Savona for safe keeping; but the course of events in 1814 forced him to liberate the pope and give back the States of the Church. On the 19th of March Pius left Savona, and was received with rejoicing at Rome on May 24. Reaction set in at Rome; the Jesuits were restored; the French legislation, much of which was of great social value, was repealed; the Index and the Inquisition were revived. On his return from the congress of Vienna Consalvi conducted a more enlightened and highly centralized administration, based largely on the famous *Motu proprio* of 1816; nevertheless the finances were in a desperate condition. Discontent centred perhaps in the *Carbonari*, a Liberal secret society condemned by the pope in 1821. Consalvi negotiated a series of valuable concordats with all the Roman Catholic powers save Austria. In the latter years of Pius's life royalty often came to Rome; the pope was very gracious to exiled kings and showed notable magnanimity toward the family of Napoleon. He attracted many artists to the city, including the greatest sculptors of the time, one of whom, the Protestant Thorwaldsen, prepared the tomb in which repose the remains of the gentle and courageous pontiff, who passed into rest on Aug. 20, 1823. His successor was Leo XII.

PIUS VIII. (Francesco Xaviero Castiglioni), pope from 1829 to 1830, was born at Cingoli on Nov. 20, 1761. He studied canon law at Rome, became vicar-general at Anagni and later at Fano; in 1800 was appointed bishop of Montalto and in 1816 of Cesena. In 1821 he was made cardinal-bishop of Frascati, also grand penitentiary; and later he became prefect of the Congregation of the Index. In the conclave which followed the death of Leo XII., Castiglioni, the candidate of France, was elected pope on March 31, 1829. He abandoned the system of espionage employed by his predecessor, and published an encyclical condemning Bible societies and secret associations. He exhibited a pacific spirit in dealing with the problem of mixed marriages in Germany. He died on Dec. 1, 1830. His successor was Gregory XVI.

PIUS IX. (Giovanni Maria Mastai-Ferretti), pope from 1846 to 1878, was born on May 13, 1792 at Sinigaglia, the fourth son of Count Jerome and Countess Catherine Vollazi; the family of Mastai was of ancient descent, and the title of count came to it in the 17th century, while later the elder branch, allied by marriage with the Ferretti family, took that name in addition. He spent some time at the College of Piarists in Volaterra, and prepared to enter the pontifical guard as an officer but was refused on the ground that he suffered from epilepsy. The malady, however, was surmounted; and in 1819 he was ordained priest. After ministering for some time in his native town, he accompanied Cardinal Muzzi to Chile (1823). On his return he was entrusted by Leo XII. with the direction of the Roman hospital of San Michele; in 1830 he received the archbishopric of Spoleto, in 1832 the bishopric of Imola, and in 1840 Gregory XVI. created him a cardinal, with the title Santi Pietro e Marecellino.

On the death of Gregory XVI. (June 1, 1846) the College of Cardinals met in conclave on June 14, and on June 16 Mastai-Ferretti obtained the requisite two-thirds majority, and ascended the papal chair under the title of Pius IX. In his various capacities he had gained much popularity: he had shown himself to be of a kindly disposition and a zealous churchman, and his reputation for piety and tact stood high; he possessed, too, a winning personality and a handsome presence.

Papal Reforms.—The reign of Pius IX. began at an extremely critical time. The problem of the government of the Papal States, transmitted to him by his predecessor, stood in urgent need of solution, for the conditions were intolerable. Dissatisfaction found vent in revolts which could only be quelled by the intervention of foreign powers; and the ferment in the dominions of the Church was accentuated by the revolutionary disturbances throughout ascendant in all the states of Europe. The proclamation of a general political amnesty made an excellent impression; and Pius at once instituted preparations for a reform of the administration, the judicature and the financial system. The regulations affecting the censorship were mitigated, and a breath of political liberalism vitalized the whole government. Pius at once acquired the reputation of a reforming pope. But two demands were urged with ever increasing energy—a share in the government and a national Italian policy. The problem of popular representation was one of peculiar difficulty in the Papal States. It was not simply a question of adjusting the claims of monarch and subject: it was necessary to oust the clergy—who, till then, had held all the more important offices—from their dominant position, or at least to limit their privileges. That the clerical character of the administration could not be indefinitely retained was plain to any clear-thinking statesman: for, since the restoration of the Papal State in 1814, the pernicious effects of this confusion of the spiritual and the secular power could no longer be denied. But Pius IX. lacked the courage and perspicacity to draw the inevitable conclusions from these premises; and the higher clergy at Rome were naturally opposed to any change which would deprive them of power and privileges. In the course of the year 1847 the pope by a series of decrees gave a reorganized municipal council to Rome and instituted a state council, and a responsible ministry, but these reforms were hedged in with reservations which made them unacceptable to the people. In March 1848 the pope promulgated a constitution, with a parliament consisting of two chambers.

Revolution of 1848.—The utility of this constitution was

never tested; for the demand for an extension of popular rights was now eclipsed by a still more passionate aspiration towards the national unity of Italy. This nationalist movement at once took head against Austria. On March 18 the revolution broke out in Milan, and King Albert of Sardinia undertook the conduct of the war against the emperor. The populace was swept by a whirlwind of enthusiasm: the Austrian embassy was mobbed; the imperial arms, surmounting the main gate of the palace, were torn down; and great troops of volunteers clamoured to be led against Austria. Pius seemed, after his proclamation of March 30, on the point of conferring his blessing upon the war against Austria. But on April 29, in his allocation to the cardinals, he proclaimed the papal neutrality; and the storm broke. Mamiani, Fabbri and Rossi, in successive ministries, sought to restore order. On Nov. 15 Rossi was assassinated as he was about to open the session of the chambers. The pope then assented to the formation of a radically democratic ministry under Galetti. The Swiss, who composed the papal guard, were disbanded; and the protection of the pontiff was transferred to the civil militia; in other words, Pius IX. was a prisoner. On Nov. 24 he fled, with the aid of the French and Bavarian ambassadors—the duc d'Harcourt and Count Spaur—to Gaeta in the kingdom of Naples. On Feb. 9, 1849 the constituent assembly decreed, by 142 votes to 23, the erection of a Roman republic. Pius answered by a protest dated Feb. 14. He had already appealed to the European Powers for assistance. For the intervention of France and Austria *see* ITALY. On July 14 Oudinot proclaimed the restoration of the pontifical dominion; and, three days later, Pius IX. issued a manifesto entrusting the government to a commission appointed by himself.

Loss of the Temporal Power.—On April 12, 1850 Pius returned to Rome, supported by foreign arms, embittered, and hostile henceforward to every form of political liberalism or national sentiment. In Gaeta he had mentally cut himself loose from all ideas of progress, and had thrown himself into the arms of the Jesuits. His subsequent policy was stamped by reaction. Whether it might have been possible to avoid the catastrophe of 1870, in which the remnant of the Papal States was lost, is a difficult question. But undoubtedly the policy which Pius now inaugurated, of restoring the old pre-revolutionary conditions, sealed the fate of the temporal dominion of the papacy. He made no attempt to regain the estranged affections of the populace, and took no measures to liberate himself and his subjects from the incubus of the last few years. The system of precautionary arrest, as it was termed, rendered it possible for any man to be thrown into prison, without trial and without verdict, simply on the ground that he lay under suspicion of plotting against the Government. The priests, who usurped the judicial function, displayed such cruelty on several occasions that officers of the Austrian army were compelled to record a protest. The consequence of these methods was that every victim—innocent or guilty—ranked as a martyr in the estimation of his fellow-citizens. Brigandage revived, corruption was rampant, and the financial administration under Cardinal Antonelli (*q.v.*) was disastrous.

The mismanagement which obtained in the papal dominions could not escape the observation of the other powers. As early as the Congress of Paris in 1856 the English ambassador, Lord Clarendon, had directed an annihilating criticism against the government of the pontiff; and a convincing proof of the justice of his verdict was given by Pius himself, in his treatment of the famous Mortara case (*see* MORTARA, EDGAR), which gave rise to diplomatic representations from France and England. The sequel to this mode of government was that the growing embitterment of the subjects of the Church came to be sympathized with outside the bounds of Italy, and the question whether the secular authority of the papacy could be allowed to continue became a much-debated problem. The continued existence of the Papal States as such, depended in fact on the maintenance of the understanding between the two powers protecting the papal state—France and Austria.

But Napoleon came to an agreement with Cavour against Austria, and one of the results of the war of 1859 was that the pope forfeited two-thirds of his dominions. After the war of 1866 (*see* ITALY: *History*), the States of the Church formed the last remaining obstacle to complete national unity. The news of the fall of the French empire in 1870 produced an electrical effect in Italy. The French troops had evacuated Rome in 1869, and the Italian parliament now called on the king to occupy Rome; on Sept. 8 Victor Emmanuel crossed the borders; and on Sept. 20 the green-white-and-red of the tricolour floated over the Capitol. The protests of Pius IX. remained unheeded, and his attempts to secure another foreign intervention met with no success. On Oct. 2 Victor Emmanuel instituted a *plébiscite* in Rome and the possessions of the Church to decide the question of annexation. The result of the suffrage was that 153,681 votes were given in favour of union with Italy, and 1,507 against the proposed incorporation: that is to say only the direct dependants of the Vatican were opposed to the change. The papal state was now merged in the kingdom of Italy, which proceeded to define its diplomatic relations with the Holy See by the law of May 13, 1871. (*See* ITALY: *History.*)

Ultramontanism.—In his capacity as head of the Church, Pius IX. adhered to the principles of the Ultramontanist party, and contributed materially to the victory of that cause. The political reaction which followed the revolutionary era in most quarters of Europe offered a favourite soil for his efforts; and in several countries he found it possible to regulate the relations between Church and state from the standpoint of the curia. In 1851 he concluded a concordat with Queen Isabella II. of Spain, proclaiming Roman Catholicism the sole religion of the Spanish people, to the exclusion of every other creed (art. 1); and we find the same provision in another concordat with the South American republic of Ecuador (1862). A third concordat, negotiated with the emperor Francis Joseph I. of Austria (1855), entrusted the supervision of schools and the censorship of literature to the clergy, recognized the canon law, and repealed all secular legislation conflicting with it. France came into line with the wishes of the pope in every respect, as Napoleon needed clerical support in his political designs. Even in Germany he found no resistance; on the contrary, he was able to secure advantageous compacts from individual states (Hesse, 1854; Württemberg, 1857).

Among the most important acts of Pius IX. must be counted his proclamation of the dogma of the Immaculate Conception of the Virgin Mary, by the bull *Ineffabilis Deus,* on Dec. 8, 1854. In this bull the preservation of Mary from every stain of hereditary sin, in the first moment of her conception, was declared to be a divinely revealed truth, which consequently demanded universal acceptance. (*See* IMMACULATE CONCEPTION.) By this means a view, which till then had been no more than a pious belief, was elevated into a dogma to be held *de fide;* though grave doubts on the subject had always been entertained, even in the midst of the Church itself. For the inner life of that Church this solution of the controversy was of great significance, and created a desire for further dogmatic decisions on the Virgin Mary—her resurrection and ascension.

As reigning sovereign of the Papal States Pius IX. had passed through a "liberal period": as head of the Church, he had never been liable to attacks of liberalism. Nevertheless, his return from exile left its mark on his spiritual administration. For from this period onwards he set his face against the influence of modernism on ecclesiastical life; showed his displeasure at and distrust of the scientific theology and philosophy which marked a moderate advance (Günther, Frohschammer and Döllinger); and, entrenched in the stronghold of mediaeval ideals, combated the transformations of the new order of society, and the changes in the relationship between Church and state, which obtained in most countries of Europe since the French Revolution. After long and careful consultation, the adverse criticisms which he had expressed on various occasions were published on Dec. 8, 1864, together with the encyclical *Quanta cura,* under the title *Syllabus complectens praecipuos nostrae aetatis errores.* (*See* SYLLABUS.) In this Pius claimed for the Church the control of all culture and all science, and of the whole educational system. He rejected the liberty of faith, conscience and worship enjoyed by other creeds; and

made an easy farewell to the idea of tolerance. He claimed the complete independence of the Church from state control; upheld the necessity of a continuance of the temporal power of the Roman See; and finally, in the last clause, declared that "the pontiff neither can be nor ought to be reconciled with progress, liberalism and modern civilization."

The publication of this syllabus created a profound impression: for it declared war on modern society, and committed the papacy to the principles of Ultramontanism (*q.v.*). But, as any attempt to translate its precepts into practice would entail a disastrous conflict with the existing régime as established by law, Roman Catholic circles have frequently shown a tendency to belittle the significance of the manifesto and to deny that its rules are absolutely binding. But these well-meant explanations, however comprehensible, are refuted by the unequivocal pronouncements of Pius IX., Leo XIII., and many recognized ecclesiastical authorities—*e.g.*, Cardinal Manning, archbishop of Westminster, who described the syllabus as an emanation from the highest doctrinal authority in the Church.

Infallibility.—The zenith of Pius's pontificate was attained on July 18, 1870, when the Vatican council proclaimed the infallibility of the pope and the universality of his episcopate, thus elevating him to a pinnacle which none of his predecessors had reached and at the same time fulfilling his dearest wish. That, personally, he laid great stress on the acceptance of the dogma, was a fact which he did not attempt to conceal during the long preliminary deliberations of the council; and his attitude was a not inconsiderable factor in determining its final resolutions. But the loss of the Papal States, immediately afterwards, was a blow from which he never recovered. Whenever he brought himself to speak of the subject—and it was not rarely—he repeated his protest in the bitterest terms, and, to the end of his days, refused to be reconciled with the "sacrilegious" king of Italy. When, in Germany, the situation created by the Vatican council led to the outbreak of the *Kulturkampf*, Pius IX. failed to display the tact peculiar to his successor. For, in the encyclical *Quod numquam* (Feb. 5, 1875), he took the rash step of declaring invalid the Prussian laws regulating the relationship between Church and state—the only result being that the feud was still further embittered.

In these later years the dark days of his "captivity" were amply compensated by the proofs of reverence displayed by Roman Catholic Christianity, which accorded him magnificent ovations as his period of jubilee began to fall due. The twenty-fifth anniversary of his pontificate was celebrated with great splendour on June 16, 1871; for he was the first pope who had thus reached the traditional "years of Peter." In 1872 his 80th birthday gave occasion for new demonstrations; and 1875 was a so-called "year of jubilee." Finally, in 1877, the fifty years of his priesthood were completed: an event which brought him innumerable expressions of loyalty and led to a great manifestation of devotion to the Holy See from all the Roman Catholic world. He will be remembered as the pope who re-established the hierarchy in England. On Feb. 7, 1878 Pius IX. died. His successor was Leo XIII. (C. Mi.; X.)

PIUS X. (Giuseppe Sarto), pope from Aug. 4, 1903, to Aug. 20, 1914, was born of humble parents on June 2, 1835, at Riete in the province of Treviso, Italy, and studied at the episcopal seminaries of Treviso and Padua, being ordained priest in 1858. For 17 years he acted as parish priest at various places in Venetia until his appointment in 1875 as canon of the cathedral and superior of the seminary at Treviso. In 1880 he refused the bishopric of Treviso, but accepted that of Mantua in 1884, at the command of Leo XIII. On June 12, 1893, he was created a cardinal and three days later was nominated patriarch of Venice, where his piety, simplicity and readiness to act in harmony with the Italian Government made him very popular. He succeeded Leo XIII. in his election to the papal chair on Aug. 4, 1903.

During his pontificate, in the defence of the faith, his condemnation of the 65 propositions of Modernism in 1907 will rank as a parallel to the condemnation of the 68 propositions of Molinism by Innocent XI. in 1637 or the 101 propositions of Jansenism condemned by Clement XI. in 1713.

Reforms of the first importance were undertaken—the codification of canon law; the protection of the liberty of the conclave by the abolition of the *exclusiva;* the simplification and security of the conditions of marriage by the *ne temere* legislation; the restoration of the Rota as the supreme court of appeal; the regulation of the triennial or quinquennial visits of bishops to Rome; the legislation as to church music; and the decree as to first communion, and the encouragement of international eucharistic congresses; the reform of the Roman breviary; the founding of the biblical institute for the work of Scriptural research; the regulation of studies in the seminaries; the creation of the commission for the great work of editing the true text of the Vulgate; the reconstruction of the official machinery of the Roman curia; the transfer of the English-speaking countries from the propaganda or missionary régime to the normal government of the Church. To these may be added in the domain of discipline the unflinching vindication by Pius X. of the Church's right to depose delinquent bishops, carried out even at the cost of rupture of diplomatic relations with France; an apostolic visitation rigorously carried out through the dioceses of Italy, resulting in four bishops being made to resign on account of neglect or inefficiency; a further regulation by which no one can be proposed for a bishopric unless his promotion receives the visa of the Holy Office, which means that his past life has been free from ecclesiastical censure or reproach.

The well-known personal characteristics of Pius X. were his piety, charity, deep humility, simplicity, pastoral zeal, combined with great charm of manner to all who approached him. For war he had nothing but horror and it was the shock of the outbreak of the World War that hastened his death, which took place in Rome on Aug. 20, 1914. It is said that one of his last acts was to refuse the request of the Austrian emperor to bless his cause, saying: "I do not bless war: I bless peace."

PIUS XI. (1857–), pope since 1922, was born on May 31, 1857, at Desio, a small town north of Monza, in the environs of Milan, on the road to Como, and was named Ambrose Damien Achille. His father was Francesco Ratti, the manager of one of the great silk factories of Desio, and partner in the firm of Gadda. Achille was educated at the seminaries of San Pietro Martire and of Monza, and at the college of St. Charles at Milan, where he graduated. Feeling that he was called to the priesthood, he studied for two years in the greater seminary. His life at this time was profoundly influenced by his spending his vacation months with his uncle, Don Rodolpho, the venerable and exemplary parish priest and provost of Asso, a village in the promontory of the Bellagio. From his windows he could see Lake Como and the Alps, of which later on he was so strongly to feel the lure. It was also here that he came under the personal notice of the archbishop of Milan, Mgr. Nazario di Calebiana, who was staying as the guest of Count de Herra and was a frequent visitor at his uncle's presbytery. The archbishop was much struck by the future pope's earnestness and maturity of judgment, and was wont to call him his "young old man." Ever afterwards he took a deep interest in his career. He sent him to the college of St. Martin and then to Rome to study at the Lombard college and attend the lectures at the Gregorian university. Here Achille Ratti took with distinction the degrees of doctor of philosophy, of theology and canon law. He was ordained priest on Dec. 20, 1879.

At the Lombard college his fellow student and closest friend

was Alessandro Lualdi, later cardinal archbishop of Palermo. These two were mentioned to the pope by Professor Liberatore as the most brilliant of his students. They were the first to win the doctorate at the Angelico, the new Thomistic college founded by Leo XIII. at Rome. The pope sent for the two students and while passing through the Clementine Hall, from his chair in which he was being carried to the Vatican gardens he delivered to them an impressive lecture upon the vital importance of a sound philosophy and of their mission in promoting it in the years which lay before them. In 1882 Dr. Ratti returned to Milan and was appointed for a period of some months to a curacy at the village of Barni.

Following up the intentions of Leo XIII., the archbishop transferred him to the Great Seminary, where he filled for five years the post of professor of dogmatic theology. In 1888 he was admitted as a member of the college of doctors at the great Ambrosian Library. This appointment gave a new direction to his scholarship. In this task, Dr. Ratti found a congenial field of labour under the guidance of the prefect of the college, the learned Abbate Cerriani. He became an expert, especially in Latin palaeography and published several studies, and contributed numerous articles to the learned reviews. In 1907 he succeeded Cerriani as prefect of the library. He was made domestic prelate by Pius X. During 1905–07 he undertook and carried out a reclassification of the library upon modern methods so as to facilitate the work of consultation and research. His success in this enterprise was recognized by the king of Italy, who bestowed on him the knighthood of the Order of Saints Maurice and Lazarus.

From 1888 onwards he was chaplain and director to the nuns of the Cenacle, an order specially devoted to the work of arranging spiritual retreats or conferences for all classes of women. At their convent he was brought into contact with all that was most distinguished and zealous among the laity of Milan and became an active organiser of their manifold works of charity. At the same time, he spent the hours that he could spare from his library in teaching the catechism to numbers of poor children, including the little chimney sweeps that annually come down from Tirol. He clung to this work during the 30 years that he remained in Milan.

He more than once visited England. In June 1900 he stayed for a time with his intimate friend, Bishop Casartelli, at Manchester. He studied at the Bodleian in Oxford and at the British Museum and said Mass in Westminster cathedral. In his summer vacations it was his custom to make climbing excursions in the Alps. The *Bolletino* of the Italian Alpine Club relates how, in 1889, he discovered a new way of ascent by the eastern slope to Monte Rosa, and how on one occasion by his courage and promptitude he saved the life of his guide. The ascent is commemorated by a monument erected by the club at Macugnaga. In 1908 during the riots at Milan, he was active in pacifying the turbulent elements and intervened successfully to save the Capucine convent from destruction during the bombardment.

Cardinal Ferrari had made him his trusted counsellor in the government of the diocese and in 1909 appointed him to a canonry in the cathedral. In 1912 Pius X. called him to Rome, made him vice-prefect of the Vatican library (where he served under Cardinal Gasquet) and at the same time promoted him to a canonry of St. Peter's. On the succession of Benedict XV. he became the familiar friend of the new pope, who, with a keen appreciation of his qualities singled him out for the diplomatic service and entrusted him with the delicate mission of apostolic visitor to the new republic of Poland. Here his clear judgment and tact and his fluent knowledge of German and Polish enabled him to achieve a marked success in dealing with the complicated claims along the Russian-Polish frontier.

In June 1919 Ratti was made nuncio apostolic in Poland and titular archbishop of Lepanto and on July 3 was consecrated in Warsaw by the archbishop, Mgr. Katowski. It was a mark of the confidence reposed in him by all classes that he was chosen by the Interallied Commission to act as high ecclesiastical commissioner for the plebiscite of Upper Silesia by agreement of both the Polish and German Governments. During the Bolshevik invasion, when most of the embassies withdrew from Warsaw, the nuncio remained and carried on his work of conciliation and of succour for the poor in devastated regions. Pope Benedict XV. sent him the pallium, the Polish Government decorated him with the Order of the White Eagle and the university enrolled him amongst its doctors. On the death of Cardinal Ferrari, Benedict XV., in June, 1921, appointed him archbishop of Milan, and made him a cardinal under the title of S.S. Silvestro and Martino ai Monti. On Sept. 2 he returned from a pilgrimage to Lourdes and on the following day was solemnly enthroned.

Pope Benedict XV. died on Jan. 22, 1922. On Feb. 2 the cardinals entered into conclave and on Feb. 6 Cardinal Ratti was elected pope. He chose the name of Pius XI., and was proclaimed from the balcony of St. Peter's. He received the triple obedience of the cardinals and on Feb. 11 was crowned in the presence of an enormous concourse in the Basilica. Since then the life of Pius XI. may be summed up as one of constant activity, in which his encouragement of all high ideals and good works has been marked by staunchness in matters of principle and the spirit of pacification and conciliation in administration. During 1925, the year of the jubilee, he was brought, perhaps more than any other pontiff, into personal contact with his spiritual subjects by receiving more than 1,250,000 pilgrims from all parts of the Catholic world. By all he is revered for his learning, his charity, piety and width of sympathy, his courtesy, tact and charm of deportment and, most of all, for his untiring devotion to the duties of his exalted pastorate. (J. Ms.)

Pope Pius XI. will go down in history as the supreme pontiff who, with the cordial co-operation of Mussolini—and their respective advisers—closed the breach between Church and State, known as the Roman Question. (*See* PAPACY.) His holiness is said to have devoted over two-and-a-half years of patient and persistent study to the problems that were involved. Examination of the *communiqués* that were available at the time of the signing of the treaties between the Holy See and Italy shows that all bore the stamp of the august humility which has always characterized Pius XI.'s utterances. He is reported to have said, on the day the treaties were signed (Feb. 11, 1929), that he had asked for the least possible indemnity because he regarded himself as a father negotiating with his children, and, therefore, he had wished to make agreement as easy as possible.

The seventh anniversary of Pius XI.'s coronation (Feb. 12, 1929) coincided with his appearance on the balcony of St. Peter's, when he gave the pontifical blessing, *Urbi et Orbi*. A crowd, 100,000 strong, gathered in the square, shouted, "Hail, Pius, Pope and King!" The ratification of the treaties by his own signature and by that of the king of Italy set the seal to documents the importance of which will appear more and more evident as time goes on.

It is now very apparent that the world has, in Pius XI., a great force making for righteousness, whose influence became all the stronger the moment it was known that the renewal of papal sovereignty carried with it no territorial expansion or material aggrandisement. A new factor has entered into the relations of the nations. The cause of universal peace and goodwill has received an historic impetus and reinforcement. Whatever view may be taken of the fact, the earth has one monarch whose power is entirely spiritual and moral, whose office it is to hold aloft the banner of the highest ideals in the eyes of a world whose vision is too often obscured by selfishness and greed

Freshfield. *See* also *Annuaire Catholique* (1923), ed. by Mgr. A. Baudrillart; *Acta Apostolicae Sedis. Commentarium Officiale* (1919–25); and *Documentation Catholique* (1922–26).

PIZARRO, FRANCISCO (*c.* 1471 or 1475–1541), discoverer and conqueror of Peru, was born at Trujillo in Estremadura, Spain, about 1471 (or 1475). He was an illegitimate son of Gonzalo Pizarro. Of Pizarro's early years hardly anything is known; but he appears to have been poorly cared for, and his education was neglected. Shortly after the news of the discovery of the New World had reached Spain he was in Seville, and thence

found his way across the Atlantic. There he is heard of in 1510 as having taken part in an expedition from Hispaniola to Urabá under Alonzo de Ojeda, by whom he was entrusted with the charge of the unfortunate settlement at San Sebastian. He accompanied Balboa (whom he afterwards helped to bring to the block) in the discovery of the Pacific.

In 1522 he entered into a partnership with a priest named Hernando de Luque, and a soldier named Diego de Almagro, for purposes of exploration and conquest towards the south. Explorations were then undertaken down the west coast of South America, in which Pizarro was left for months with but 13 followers on the island of Gallo, without ship or stores. There it was that Pizarro displayed the courage which has made famous the story of himself and his companions. (Some authorities, among them Xeres, Pizarro's secretary, give the number of his companions as 16. Herrera states the names of 13; Garcilasso supplies the remaining three.) But Pizarro persisted till he had coasted as far as about 9° south and obtained distinct accounts of the Peruvian empire. The governor of Panama showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panama for Spain, accompanied by Pedro de Candia, in the spring of 1528, reaching Seville in early summer. Charles V. was won over. Pizarro was decorated with the order of Santiago, was granted a coat-of-arms and 13 of his heroic companions were ennobled by name.

On July 26, 1529, was executed at Toledo the famous *capitulación,* by which Pizarro was upon certain conditions made governor and captain general of the province of New Castile for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a viceroy, his associates being left in wholly secondary positions. One of the conditions of the grant was that within six months Pizarro should raise a sufficiently equipped force of men, of whom 100 might be drawn from the colonies; as he could not make up his due complement he sailed clandestinely from San Lucar in Jan. 1530. He was afterwards joined by his brother Hernando with the remaining vessels, and when the expedition left Panama in January of the following year it numbered three ships, 180 men and 27 horses. The subsequent movements of Pizarro belong to the history of Peru (*q.v.*). After the final effort of the Incas to recover Cuzco from 1536 to 1537 had been defeated by Diego de Almagro, a dispute occurred between him and Pizarro respecting the limits of their jurisdiction. This led to battle; Almagro was defeated (1538) and executed; but his supporters conspired, and assassinated Pizarro on June 26, 1541.

PIZARRO, GONZALO (?1505–1548), explorer, half-brother of Francisco Pizarro, was born at Truxillo in 1505 or 1506 He accompanied the Peruvian expedition in 1531, and received for his services extensive grants in the Potosi mines. In 1539 he was made governor of Quito, and in 1541–42 he led an expedition east of Quito in the course of which Francisco de Orellan explored the Amazon. Two years later he defeated Vela, the new viceroy, and was declared governor of Peru, but in 1548 he was himself defeated by a Spanish force under Pedro de la Casco, was compelled to surrender and was executed on April 10, 1548.

PIZZICATO, a musical term indicating that a given passage for a stringed instrument is to be plucked by the fingers instead of played by the bow.

PLACARD, a bill or poster pasted or affixed to a wall or in any prominent position. (*See* Poster.)

PLACE, FRANCIS (1771–1854), radical reformer, was born on Nov. 3, 1771, and later apprenticed to a leather-breeches maker. He suffered great hardships owing to the decline of this trade, and in 1793 organized an unsuccessful strike of London breeches-makers. He acted as secretary to other trade clubs and from 1794–97 was prominent in the London Corresponding Society. He used his frequent enforced leisure for self-education, especially in political economy, and became a great admirer of Bentham. In 1799 he and a partner opened a tailoring shop in Charing Cross road, and the next year he went into business alone, rapidly becoming so successful that in one year he made £3,000. He was already known as a Radical politician when in 1814 he took up seriously a campaign to secure the repeal of the Combination Acts forbidding trade unions. For some years he met with little success, but in 1824, acting through Joseph Hume, M.P, he secured a parliamentary committee "on artisans and machinery" which reported in favour of the abolition of the acts. Bills to this effect were carried, amid general indifference; the premier, indeed, afterwards assured the House of Commons that he had no idea of the contents of the bills when he recommended them. The immediate effect of the repeal was a sudden increase in the number and activity of trade unions, and next year the Government attempted to restore the prohibition. The public excitement and the interest of the working-men were such that after a parliamentary struggle of an unusual stiffness, Place secured the passing of an act which scarcely altered the position.

His skilled political organization made the Westminster elections from 1807–32 events of national importance in the struggle for parliamentary reform. In 1831 and 1832 he greatly assisted behind the scenes in the preparations for military revolt should the Lords remain obstinate. Together with Joseph Parkes of Birmingham he framed the placard "TO STOP THE DUKE, GO FOR GOLD" which produced the run on the banks that drove Wellington from office and carried the Reform bill without violence. He also disorganized the "Rotundanist" reformers, who wished the extension of the franchise to the working class, by the organization of a "tame" working class union at the height of the struggle. He died at the age of 83, having been for many years out of politics.

See Graham Wallas, *Francis Place* (1918). Place's mss. and guard-books, an incomparable source of political information from 1790 to 1850, are in the British Museum. (R. W. P.)

PLACE-NAMES. Ancient historians often speculated upon the meaning of place-names, inventing persons who are presumed to have been the first founders of the country and to have left their mark on its nomenclature. But it is only within the last half-century that attempts have been made to lay the foundations of a science of place-names. Förstemann in Germany, Rygh in Norway, Noreen in Sweden, Skeat in England, Longnon in France, are perhaps the best-known pioneers in this work. The main foundations upon which they built were the recognition (1) that no place-name can be interpreted in the light of its present-day form alone, but must be traced back to its earliest recorded form, (2) that no explanation of a place-name, however convincing as philology, can hold good if inconsistent with the known history and topography of the site, and, conversely that no explanation based upon legend or topography, is of value if inconsistent with philology.

Processes of Change.—The ordinary word is to some extent controlled by the written or printed book. But the transmission of most place names is still very largely oral, and as the name is merely a name, and rarely has any significance in itself, at least to its modern user, there is little or nothing to check the process of change. The natural result is that the modern form of the name is often misleading. *Cenwulfesleah* has become *Knowsley, Tidwulfestreo* has become *Elstree;* and *Cholmondeley, Cirencester, Auchinleck,* and *Wymondham,* while in spelling they retain something like their original form, in pronunciation have been reduced to *Chumley, Sissiter, Affleck* and *Wyndham.* (It should be noted that the spread of the printed word and universal primary education are now tending to reverse the process and to substitute spelling-pronunciations for the genuine local ones.) The lack of stress upon the final element together with certain common sound-assimilations have obscured the history of many names. Thus *Embleton* really should end in *don,* "hill." *Hallington* is really *"holy dene"* (the site of the battle of "Heavenfield"), *Warden*-on-Tyne is a "watch *don*" or "hill" at the junction of north and south Tyne. So, also, nearly all the place-names in *-hall,* such as *Willen-*

hall, really end in *hale*, "nook" or "corner of land." The proximity of some similar sounding name may lead to its ultimate substitution as when *Combe-in-Teignhead* replaces *Combe-in-Tenhide* because the place stands on a headland at the mouth of the *Teign*.

Folk-Etymology.—When we come across a name which in itself conveys no meaning we are apt to turn it into something which conveys some sort of meaning, however inapposite. Thus all the places once called *Fivehide* have now become *Fivehead* or *Fyfield*, since we are no longer aware what a "hide" of land is. *Highenovre* (lit. "high bank") becomes *High and Over*. Folk-etymology has led to the formation of a series of "ghost" place-names, commonly spoken of as "back-formations." *Cambridge* is assumed to be the "bridge over the Cam" and the river is henceforward so called, though in reality *Cambridge* is an Anglo-Norman corruption of an earlier *Grantabrycg* and the correct name of the river is *Granta*. This process is specially common with river-names. The Sussex *Arun* and *Rother* are back-formations from *Arundel* and *Rotherfield*, while the *Adur* is a back-formation from the false identification of *Portus Adurni* with Shoreham. The old names for the rivers, in this case *Tarrant, Limen, Bramber*, were early lost and new names had to be found.

Early forms of certain names may be recorded by early geographers, historians or chroniclers but for most we have to turn elsewhere, to national surveys such as *Domesday Book* or the Danish Landbook of King Valdemar, to ancient charters, which often give not only the name of the land granted but also the names of the land-marks on its boundaries, royal and episcopal documents of every kind and, in later days, surveys, extents, terriers, maps. Here fresh difficulties arise. We find a large number of faulty and fantastic spellings, as when *Knighton* (O.E. *cnihtatun*) commonly appears in Domesday as *Chenistetone*, or *Gilling* (O.E. *Gillingas*) is disguised as *Gwyllingues*. Such forms, if they appeared repeatedly in official documents, might actually be recognized as the correct names even locally. Thus the *Ciren-* of *Cirencester* is the Norman-French spelling for the native English *Churn*, the river on which that town stands, and *Durham* is the result of the Norman's attempt to pronounce *Dunholm*, in which the sound-combinations *nh* and *lm* proved too difficult for him.

Interpretation.—In the interpretation of early forms, we have, first, words descriptive of the actual topography and secondly personal names belonging to those who have been owners or occupiers of the site. Most of the descriptive words can readily be recognized but a goodly number furnish difficulties. Our knowledge of the vocabulary of our forefathers is derived chiefly from works of religious or homiletic character and there are extensive gaps in our knowledge of their secular vocabulary, especially in its earliest stages. These lost words may be found in place-names. Thus in *Herne* (Beds) and *Harome* (Yorks) we have an otherwise unknown O.E. *har*, "a stony place, heap, hill," found in various cognate languages. So also a word in common use in early days may have passed completely out of use in our language and still survive in place-names. O.E. *hearg*, "heathen grove" only survives in such place-names as *Harrow, Harrowden* and *Arrow* Hill. And similar difficulties arise with regard to the personal names found in place-names. Often when a personal name has been assumed the very name itself turns up later in some newly discovered document. Thus a personal name *Blicc* with a diminutive *Bliccel* was assumed to explain *Blickling* and then later the name was found in a 12th century cartulary.

In most countries we have to deal not with one people or language alone but with successive settlements by peoples using different languages. If the new race is only a powerful minority, as for example the Normans in England or the English in Ireland, its influence on place-names may be very small. In the case of the Romans in Celtic Britain it was almost negligible. If the invasion or settlement was a mass one, there may be very extensive renaming of the places, as was the case with the English in most parts of England, the Vikings in certain parts of the Danelaw and in Normandy, and the Celtic refugees who settled in Brittany. In England the dominant race and speech since the beginning of the 6th century has been English and, except in Cornwall, Monmouthshire and Herefordshire, the nomenclature of the counties of England is predominantly English or Scandinavian. The only exception to this general statement is to be found in a good number of the names of natural features, such as rivers and mountains. Here, and in other countries also, the old names were usually kept. The rivers ran through wide tracts of country and were not the property of any single settler, while the mountains had no attractions for settlers in search of good pasture or arable land. Thus it is that *Wear, Tyne, Avon, Cheviot, Eildon, Malvern, Mendip*, are Celtic names, though English ones are not entirely wanting, as, for example, *Blyth, Loud, Clent*. Many river and hill-names cannot be explained even upon a Celtic basis and may have been taken over by the Celts from still earlier peoples. We must also note that some names which now look convincingly English may really be folk-etymological perversions of earlier Celtic names. The Celtic name has in a few cases survived to prove it, as in the case of O.E. in *Eoforwic, Searoburh* our *York* and *Salisbury*, which mean in Old English "boar-dwelling" and "trickery-fort" respectively but are really anglicisings of the old Romano-Celtic names *Eburacum* and *Sorbiodunum*. How many similar cases there may be in which the evidence for it has not chanced to survive it is impossible to say.

The Romans seldom renamed the British towns, and beyond one or two somewhat doubtful examples, such as *Speen* and *Chester* (earlier *Lega-ceaster*) and *Lincoln* from the Latin *spinae*, (*urbs*) *legionis* and *Lindum colonia*, they left little to be handed on to the English. The latter had picked up a certain number of Latin words both in their old Continental homes and in England through the channels of war and trade and Christianity, such as *castra*, (*via*) *strata, monasterium*. These became *ceaster, Strat* and *mynster* in their own language and have given rise to groups of names in *-chester, -cester, -caster*, in *Street-, Stret-, Strat-, Streat-* and in *-minster*. The first of these elements is very commonly found in the names of the old Romano-British fortified towns, but it should be noted that the first element in such names (*e.g., Gloucester, Cirencester, Wroxeter, Exeter*) is Celtic and not Roman, the old names being *Glevum, Corinium, Uriconium* and *Isca*.

The English Conquest involved widespread renaming of the countryside. The comparative frequency of place-names in *-ing* and *-ingham* in the eastern and south-eastern counties and their comparative rarity elsewhere suggests the importance of the great leader and his followers in the early stages of the invasion, for in O.E. the suffix *ing(as)* was added to a personal name to denote that man and his family, followers, etc. Thus *Basing* denotes the "followers of Basa" and *Whittingham* is the "home of the followers of Hwita." The elements *ham* and *stede*, "site," "place," later *ste(a)d*, were freely used in the early days of the invasion. The suffix *ton*, from O.E. *tun* "enclosure" becomes relatively much more frequent as we travel westwards to the districts latest conquered and this suffix remained a living one till long after the Norman Conquest. *Worth, worthy* and *wardine* all denote small enclosures but the first soon ceased to be a living suffix. *Port* was used for a town (a loan-word from Lat. *porta*), and *burh* (dat. sing. *byrig*) is the source of many names in *bury* and a few in *borough, burgh*. It denotes a fortified place, of whatever age, and has none of the constitutional associations of the common word *borough*. Large areas of land were still covered with forest; as these were brought under cultivation names in *-ley* and *-field* arose, from the O.E. words *leah*, "clearing in woodland," and *feld*, "open country." Land dedicated to the service of religion was often called *stow*, hence *Halstow*, "holy place," *Bridstow*, "St. Bride's land," corresponding to the Welsh *Llan san Bregit*. Many other elements of a purely topographical character are found in place-names. Here and in other countries we find early peoples very sensitive to slight differences of terrain and a place might be called a *cliff*, e.g., *Egglescliffe*, or *hangra* (*i.e.*, "hanging wood," as in *Shelfanger*), where we should only note a slight slope. The personal names found in these place-names, especially in eastern and south-eastern England, are often of an exceedingly archaic type, suggesting that soon after the settlement there were rapid changes in the nomenclature among our forefathers.

The Scandinavian settlement of certain districts of England

affected the place-nomenclature as deeply as the earlier English settlements, but its intensity varied a good deal from area to area and as the speech of the Vikings was closely allied it is not always easy to differentiate native and Scandinavian names. Changes were brought about in various ways. The commonest was entirely to re-name the place, as when O.E. *Nor-worig* became *Derby*. There was also a good deal of Scandinavianizing of names, as when O.E. *Eofor-wic* became *Jor-vik* (and so *Yorick* and *York*) or places which had once ended in *-bury* were given the Scandinavian suffix *-by*, so that in the middle of the 10th century *Badby* (Northants.) is called indifferently *Baddanby* and *Baddanburh*. How deep the influence of Scandinavian speech went is shown by more than one place-name which retains Scandinavian inflexional forms (e.g., *Beckermet*, "meeting of the stream," which contains the gen. sing. *bekkjar* of O.Norse *bekkr*, and still more by a name like *Osmotherley* in which the English personal name *Osmund* was given a Scandinavian gen. sing. in *ar* even before an English second element). In some counties, where raids were extensive but where there was no organized dividing up of the land among the new settlers (*e.g.*, Northumberland and a good part of Durham), the number of Scandinavian names is small but in others (*e.g.*, the North and East Ridings of Yorkshire and in Lindsey), where the land was parcelled out among the Danish, we have a dominantly Scandinavian nomenclature. Danes for the most part settled in eastern England, Norsemen in northwestern England. That there were some colonies of Norsemen amid a prevailing Danish population is shown by the *Normanbys* and *Normantons* in the east and the Midlands, all settlements of Norsemen and not of Normans. In the North Riding there were enough Norsemen for certain villages to have to be distinguished as *Danby*, "villages of the Danes." Where the English were almost entirely ousted we have a few *Inglebys*, isolated villages of the English surviving, while the *Denbys* and *Denaby* of Derbyshire and the West Riding suggest Danish settlements amid a prevalent English population. Those Vikings, chiefly Norsemen, who had previously been raiding in Ireland were commonly known as the "Irishmen" and gave their name to certain *Irbys*, *Irebys* and *Iretons*. When they had been to Wales they were nicknamed *Brettar* and so we get *Bretby* and two or three *Birkbys*, which were earlier *Brettaby*. The commonest suffixes denoting various kinds of settlement are as follows: *by*, denoting variously farm, hamlet and village, *thorpe*, "a village," especially an "offshoot from a larger one" (carefully to be distinguished from the native *thorp, throp*, often found in the South Midlands, as in *Eythrope, Thrupp, Sedrup, Colstrope*), *thwaite*, "clearing," "paddock," *toft*, "piece of ground," "messuage," "homestead." To the Vikings also we owe the *ridings* of Yorkshire and Lincolnshire, from O.Norse *thrithungr*, "third part" and the *wapentakes* of Scandinavian England generally, from O. Norse *vapna-tak*, "taking of weapons." They had their own topographical terms, some of the commonest being found in the suffixes *scoe, skew* "wood," *with*, "wood," *force*, "waterfall," *fell*, "mountain," Norse *breck* and Danish *brink* "slope," *wath*, "ford," Norse *slack*, "shallow valley." Personal names are very common as first elements in their place-names while in a few we have post-position of the personal name (e.g., *Aspatria*, lit. ash-Patrick), showing that the Norsemen when in Ireland must have learned the old Gaelic method of putting the personal name after the significant element. This name and others, such as *Commondale*, earlier *Colmandale*, containing the O.Ir. name *Colman* show how common Gaelic names were among these Vikings who had intermarried with the Celts. In gauging Scandinavian influence on the basis of place-names it should be borne in mind that many Scandinavian words (e.g., *biggin, fell*) soon became part of the English speech and that certain Scandinavian names such as *Harold* soon came to be borne by persons of English descent, so that the presence of such elements in place-names is no certain proof of their Scandinavian origin.

The main sphere of Norman-French influence on place-names has already been indicated, viz., its importance in changing the spelling and pronunciation of many of the older names. Such influence was specially common in the neighbourhood of the great castles and monasteries. They themselves often bore French, or at least Gallicised names, such as *Richmond, Devizes, Belvoir, Rievaulx, Jervaulx*. The traditional pronunciations of these names are Anglo-French in character and thus it is that we have *Bewley* for *Beaulieu*, *Beaver* for *Belvoir, Rivers* for *Rievaulx*, and *Beaumont* commonly pronounced as *Beamont* or *Bewmont*. Knowledge of modern French is gradually ousting these in favour of pseudo-educated ones. Norman-French feudalism led to the distinguishing of one manor from another by the suffixing (or occasional prefixing) of the name of its feudal holder, whence such names as *Stanstead Mountfitchet, Buckland Sororum* (*i.e.*, of the nuns), *Bishop's Tawton*.

The more one studies the history of place-names the more one finds what a large proportion of them are really early in their origin. There are however two types which are definitely late. The type whereby a place came to be called *Poynatts, Chequers*, and the like, from the family names, *Poynatt, Chequer*, dates from the 14th century onwards. Place-names formed from phrases, often of a humorous character, such as *Glororum* (glower o'er 'em), *Make 'em Rich, Bo-peep* come even later, belonging as a rule to the 17th century or later.

BIBLIOGRAPHY.—England: The English Place-name Society, with the help of the British Academy, is carrying through a survey of English place-names and has published volumes on Bucks., Beds., Hunts., Worcs., the North Riding of Yorks. and Sussex, together with an Introductory volume and one on the *Chief Elements* (1924–. In progress). Skeat has volumes on Cambs., Beds., Hunts., Herts., Suffolk, Berks. (1901–13), Moorman on the West Riding (1910), Stenton on Berks. (1911), Duignan on Staffs., Worcs., Warw. (1905–12), Baddeley on Gloucs., Bannister on Heref. (1913), Goodall on S.W. Yorks., Walker on Derbys. (1914), Alexander on Oxon. (1912), Ekblom on Wilts. (1917), Sedgefield on Cumberland and Westmorland (1915), Mawer on Northumberland and Durham (1920), Ekwall on Lancs., Gover on Middlesex (1922). Monographs on particular subjects are Ekwall on *Place-names in -ing* (1923) and on *River-names of England* (1928), Lindkvist on *Middle English Place-names of Scandinavian Origin* (1912), Zachrisson, *Anglo-Norman Influence on English Place-names* (1909). Wales: No systematic work but Johnston, *Place-names of England and Wales* (1914) includes a good many. Scotland: Johnston, *Place-names of Scotland* (1903), and Watson, *The Celtic Place-names of Scotland* (1927). Ireland: Joyce, *Origin and History of Irish names of places* (1875–1901). Isle of Man: Kneen, *Place-names of the Isle of Man* (1926–28).

France: Longnon, *Les noms de lieu de la France* (1920–23), incomplete.

Germany: Förstemann-Jellinghaus, *Altdeutsches Namenbuch, Ortsnamen* (1913–16), including many Teutonic place-names from other Continental countries.

Norway: *Norske Gaardnavne* (1897–1919), *Norske Elvenavne* (1904), *Indledning* (1898) by Rygh, Olsen and others. Sweden: *Sverges Ortnamn* (1909–. In progress), *Ortnamen i Göteborgs och Bohus Län* (1923–. In progress), Lindroth, *Våra ortnamen* (1923). Denmark: *Danmarks Stednavne* (1922–. In progress), Steenstrup, *Indledende Studier* (1909), *De Danske Stednavne* (1919).

Holland: *Nomina Geographica Neerlandica* (1892–1901). Flanders: *Woordenboek der Toponymie* (1914–. In progress), Mansion, *Oud-Gentsche Naamkunde* (1924).

The periodicals *Namn och Bygd* (1913–) and *Zeitschrift für Ortsnamenforschung* (1926–) cover the chief European countries.

(A. M.)

PLACENTA, the organ by which the embryo is nourished within the womb of its mother. When the young one is born the placenta and membranes come away as the "afterbirth." The human placenta is a circular disk about 7 or 8 in. in diameter and 1¼ in. in thickness at its centre, while at its margin it is very thin and is continuous with the foetal membranes. It weighs about a pound.

Mode of Formation.—Before each menstrual period, during the child-bearing age of a woman, the mucous membrane of the uterus hypertrophies, and, at the period, is cast off, but if a fertilized ovum reaches the uterus the casting off is postponed until the birth of the child. From the fact that the thickened mucous membrane lining the interior of the uterus is cast off sooner or later, it is spoken of as the "decidua." The fertilized ovum, on reaching the uterus, embeds itself in the already prepared decidua, and, as it enlarges, there is one part of the decidua lying between it and the uterine wall ("decidua serotina" or "basalis"), one part stretched over the surface of the enlarging ovum ("decidua reflexa" or "capsularis") and one part lining the rest of the uterus ("decidua vera") (*see* fig. 1) It is the decidua

basalis which is specially concerned in formation of the placenta. That part which is nearest the ovum is called the "stratum compactum," but farther away the uterine glands dilate and give a spongy appearance to the mucous membrane (stratum spongiosum). Processes from the surface of the ovum penetrate the stratum compactum and push their way into the enlarged maternal blood sinuses; these are the "chorionic villi." Later,

FIG. 1.—DIAGRAM REPRESENTING A VERY YOUNG HUMAN OVUM ALMOST IMMEDIATELY AFTER ITS ENTRANCE INTO THE DECIDUA. THE PLACE OF ENTRANCE STILL BEING COVERED WITH A PLUG OF FIBRIN

the "allantoic" or "abdominal stalk" grows from the mesoderm of the hind end of the embryo into the chorionic villi which enter the decidua basalis, and in this blood-vessels push their way into the maternal blood sinuses. Eventually the original walls of these sinuses and the false amnion, disappear, and nothing separates the maternal from the foetal blood except the delicate walls of the foetal vessels covered by undifferentiated, nucleated tissue (*syncytium*), derived from the chorionic epithelium, so that the embryo is able to take its supply of oxygen and materials for growth from the blood of its mother and to give up carbonic acid and excretory matters. It is the gradual enlargement of the chorionic villi in the decidua basalis together with the intervillous maternal blood sinuses that forms the placenta; the decidua capsularis and vera become pressed together as the embryo enlarges, and atrophy. The allantoic stalk elongates enormously, and in its later stages contains two arteries (umbilical) and one vein embedded in loose connective tissue known as "Wharton's jelly." At first the stalk of the yolk-sac is quite distinct from this, but later the two structures become bound together (*see* fig. 2), as the "umbilical cord." A distinction must be made between the allantoic stalk and the allantois; the latter is an entodermal outgrowth from the hind end of the mesodaeum or primitive alimentary canal, which in the human subject only reaches a little way toward the placenta. The allantoic stalk is the mass of mesoderm containing blood-vessels which is pushed in front of the allantois and, as has been shown, reaches and blends with the decidua basalis to form the placenta.

For further details *see* Quain's *Anatomy*, vol. i. (London, 1908); and, for literature, O. Hertwig's *Handbuch der Entwickelungslehre* (Jena).

Comparative Anatomy.—If the placenta is to be regarded as a close union between the vascular system of the parent and embryo, the condition may be found scattered throughout the phylum of the Chordata. In so lowly a member as Salpa, a placenta is formed, and the embryo is nourished within the body of its parent. In some of the viviparous sharks, *e.g.*, the blue shark (Cacharias), the yolk-sac has ridges which fit into grooves in the wall of the oviduct and allow interchange between maternal and foetal blood. This is an example of an "umbilical placenta." In the viviparous blennies (*Zoarces viviparus*), among the teleostean fishes, 200 or 300 young are nourished in the hollow ovary, which develops villi secreting nutritive material.

The mammals are divided into Placentalia and Aplacentalia; in the latter group, to which the monotremes and most marsupials belong, the ova have a great deal of yolk, and the young, born in a very immature condition, finish their development in their mother's pouch; but although these mammals have no allantoic placenta there is an intimate connection between the walls of the yolk-sac and the uterine mucous membrane, and so an umbilical placenta exists. The name Aplacentalia therefore only means that they have no allantoic placenta. Among the Placentalia the umbilical and allantoic placentae sometimes coexist for some time, as in the hedgehog, bandicoot and mouse.

In the Carnivora, elephant, procavia (Hyrax) and aard vark (Orycteropus), there is a "zonary-placenta" which forms a girdle round the embryo. In sloths and lemurs the placenta is dome-shaped, while in rodents, insectivores and bats, it is a ventral disk or closely applied pair of disks, thus differing from the dorsal disk of the ant-eater, armadillo and higher Primates, which is known as a "metadiscoidal placenta." Thus the form of the placenta is not an altogether trustworthy indication of the systemic position of its owner. In the diffuse and cotyledonous placentae the villi do not penetrate very deeply into the decidua, and at

FIG. 2.—DIAGRAM OF THE LATER STAGE IN THE DEVELOPMENT OF THE PLACENTA, SHOWING THE RELATIONS OF THE FOETAL VILLI TO THE PLACENTAL SINUSES, FUSION OF THE AMNION WITH THE INNER SURFACE OF THE CHORION, AND THE THINNING OF THE FUSED DECIDUAE

birth are simply withdrawn, the decidua being left behind in the uterus, so that these placentae are spoken of as non-deciduate while other kinds are deciduate.

PLACERS, the common name given to the alluvial deposits in which gold frequently occurs. They consist of sand and gravel deposited by existing or former streams of water carrying de-

tritus of gold-bearing rocks. Other metals, *e.g.*, tin, are similarly deposited. The gold of the placers consists of grains called "gold-dust" and larger pieces, rounded by attrition, called "nuggets." The placer of an ancient stream may be deep-lying because covered since its formation with other deposits or even lava. (*See* GOLD MINING and METALLURGY.)

PLAGIARISM, an appropriation or copying from the work of another, in literature or art, and the passing off of the same as original. The Lat. *plagiarius* meant a kidnapper, stealer or abductor of a slave or child, though it is also used in the modern sense by Martial (I. 53, 9). (*See* COPYRIGHT.)

PLAGIOCLASE, an important group of rock-forming minerals constituting an isomorphous series between albite felspar and anorthite felspar. The intermediate members are soda-lime felspar which in their crystallographical, optical and other physical properties vary progressively between the two extremes, albite (Ab) $NaAlSi_3O_8$, and anorthite (An) $CaAlSi_2O_8$. The name plagioclase is derived from the Gr. *πλάγιος,* "oblique," and *κλᾶν,* "to break," in allusion to the oblique angle between the cleavages. Names are applied to members of the plagioclase group falling between certain arbitrary composition limits, those now commonly adopted being albite (Ab_{100}–Ab_{90}), oligoclase (Ab_{90}–Ab_{70}), andesine (Ab_{70}–Ab_{50}), labradorite (Ab_{50}–Ab_{30}), bytownite (Ab_{30}–Ab_{10}), anorthite (Ab_{10}–An_{100}). The pure end members are practically unknown in nature. All the plagioclases crystallize in the triclinic system, and as members of an isomorphous series show closely similar crystallographic constants. They possess a perfect cleavage parallel to the basal pinacoid (001) and a less pronounced cleavage parallel to the pinacoid (010), the angle between the two cleavages varying progressively from 86° 24′ in albite to 85° 50′ in anorthite. The molecular volumes are closely similar (Ab 100·1) (An 101·5). The habit of well-formed crystals is usually tabular on the plane 010, sometimes flattened parallel to 001 or, as in microlitic plagioclases of volcanic rocks, elongated in the direction of the edge 001:010. Twinning is a very important character of the plagioclases, being almost invariably present and affording a ready means of distinguishing them from other felspars. The chief twin laws are the Carlsbad, albite and pericline; the latter two, being commonly polysynthetic, give rise to numerous thin lamellae, which are the cause of the fine striations seen on cleavage planes, and of the banded character visible in thin sections of the minerals examined in polarized light.

With the exception of the sodic end member (albite), which, owing to the high viscosity of its melts, is with difficulty crystallized, the plagioclases are readily prepared from dry melts of the component oxides. They show a continuous melting curve, the intermediate members exhibiting a melting interval. The temperatures of beginning of melting (solidus) have been determined in the laboratory for compositions ranging from pure An to Ab_3An_1, and of completion of melting (liquidus) for a range An to Ab_8An_1. These data are shown below.

Composition	*Temperature of beginning of melting (solidus)*	*Temperature of completion of melting (liquidus)*
Albite ($Ab_{98}An_2$)	1,100°C	—
Oligoclase (Ab_3An_1)	1,175°C	1,362°C
Andesine (Ab_2An_1)	1,205°C	1,394°C
Andesine-Labradorite (Ab_1An_1)	1,287°C	1,450°C
Labradorite (Ab_1An_2)	1,372°C	1,490°C
Bytownite (Ab_1An_5)	1,465°C	1,521°C
Anorthite (An_{100})	1,550°C	1,550°C

The density and mean refractive index of the plagioclase felspars vary progressively, the extremes being albite, $D = 2{\cdot}605, \mu = 1{\cdot}530$; anorthite, $D = 2{\cdot}765, \mu = 1{\cdot}587$.

Since the plagioclases are of great importance in petrology much detailed study of their optical properties has been undertaken, so that it is now possible to determine by simple examination of thin slices of these minerals the exact chemical composition and crystallographic orientation of the selected section. For this purpose, the chief determinations are the refractive indices, and the optical extinctions of oriented sections, principally on cleavage flakes (001 and 010), sections cut perpendicular to the optic axes and bisectrices, and especially those perpendicular to the plane of albite twinning (010) in multiple-twinned crystals. Other optical determinations are available for discriminating the various members of the group.

BIBLIOGRAPHY.—For a detailed summary of the optical characters, and their employment in the recognition of the quantitative composition of the felspars, the following should be consulted: H. Rosenbusch, *Mikroskopische Physiographie der Mineralien und Gesteine* (Band i., Zweite Hälfte, 5 Auflage, revised by O. Mügge, 1927); L. Duparc and M. Reinhard, "La Détermination des Plagioclases" (*Mem. Soc. Phys. Hist. Nat. Genève,* xl., 1924, fasc. 1.); A. N. Winchell, *Elements of Optical Mineralogy* (pt. 2, 1927, pp. 277–341). For a recent preliminary X-ray study of the plagioclase felspars, reference may also be made to E. Schiebold, *Fortschritte der Mineralogie, Kristallographie und Petrographie* (Band xii., 1927, pp. 78–82). A more detailed account of the occurrence of the various members is given under ALBITE, OLIGOCLASE, ANDESINE, LABRADORITE, BYTOWNITE, ANORTHITE. *See* also FELSPAR. (C. E. T.)

PLAGUE, in medicine, a term formerly given to any epidemic disease causing a great mortality, but now confined to a specific infectious fever caused by *b. pestis.*

History to 1880.—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the *Collections of Oribasius*[1]. Rufus speaks of the buboes called pestilential as being specially fatal and as being found chiefly in Libya, Egypt and Syria. This passage shows the antiquity of the plague in northern Africa, which for centuries was considered as its home. It is not till the 6th century of our era, that we find bubonic plague in Europe, as a part of the great cycle of pestilence, which lasted fifty years, and spread over the whole Roman world, beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were the plague cannot now be said; but it is possible the pestilences in England chronicled by Bede in the years 664, 672, 679 and 683 may have been of this disease, especially as in 690 *pestis inguinaria* is again recorded in Rome.

In the great cycle of epidemics in the 14th century known as the Black Death, some at least were bubonic plague. The mortality of the black death was, as is well known, enormous. It is estimated in various parts of Europe at two-thirds or three-fourths of the population in the first pestilence, in England even higher; but some countries were much less severely affected. Hecker calculates that one-fourth of the population of Europe, or 25 millions of persons, died in the whole of the epidemics.

The Great Plague of London.—The great plague of 1664–1665 must not be regarded as an isolated phenomenon. Plague had recurred frequently in all parts of Europe in the 15th, 16th and 17th centuries. Nevertheless in London the preceding years had been unusually free from plague, and it was not mentioned in the bills of mortality till in the autumn of 1664 (Nov. 2) a few isolated cases were observed in Westminster and a few occurred in the following winter, which was very severe. About May 1665 the disease again became noticeable and spread, but somewhat slowly. Boghurst, a contemporary doctor, notices that it crept down Holborn and took six months to travel from the western suburbs to the eastern through the city. The mortality rapidly rose from 43 in May to 590 in June, 6,137 in July, 17,036 in August, 31,159 in September, after which it began to decline. The total number of deaths from plague in that year, according to the bills of mortality, was 68,596, in a population estimated at 460,000, out of whom two-thirds are supposed to have fled to escape the contagion. This number is likely to be underestimated, since of the 6,432 recorded deaths from spotted fever many were probably really from plague, though not declared so to avoid painful restrictions. In December there was a sudden fall in the mortality which continued through the winter; but in 1666 nearly 2,000 deaths are recorded.

According to some authorities, the plague was imported into London by bales of merchandise from Holland, which came originally from the Levant; according to others it was introduced

[1]Lib. xliv. cap. 17—*Oeuvres de Oribase,* ed. Bussemaker and Daremberg (Paris, 1851), iii. 607.

by Dutch prisoners of war. From London the disease spread widely over England.

After 1666 there was no epidemic of plague in London or any part of England, though sporadic cases appear in bills of mortality up to 1679; and a column filled up with "o" was left till 1703, when it finally disappeared. The disappearance of plague in London was attributed to the Great Fire, but no such cause existed in other cities. It has also been ascribed to quarantine, but no effective quarantine was established till 1720, so that the cessation of plague in England must be regarded as spontaneous.

But this was no isolated fact. A similar cessation of plague was noted soon after in the greater part of western Europe. In 1666 a severe plague raged in Cologne and on the Rhine, which was prolonged till 1670 in the district. In the Netherlands there was plague in 1667–1669, but there are no definite notices of it after 1672. France saw the last plague epidemic in 1668, till it reappeared in 1720. In the years 1675–1684 a new plague epidemic appeared in North Africa, Turkey, Poland, Hungary, Austria and Germany, progressing generally northward. Malta lost 11,000 persons in 1675. The plague of Vienna in 1679 was very severe, causing 76,000 or probably more deaths. Prague in 1681 lost 83,000 by plague. Dresden was affected in 1680, Magdeburg and Halle in 1682—in the latter town with a mortality of 4,397 out of a population of about 10,000. Many North German cities suffered about the same time; but in 1683 the plague disappeared from Germany till the epidemic of 1707. In Spain it ceased about 1681; in Italy certain cities were attacked till the end of the century, but not later (Hirsch).

The plague-epidemics in Egypt between 1833 and 1845 are very important in the history of plague, since the disease was almost for the first time scientifically studied in its home by skilled European physicians, chiefly French. The disease was found to be less contagious than reported to be by popular tradition, and most of the French school went so far as to deny the contagiousness of the disease altogether.

An outbreak of plague in 1878–1879 on the banks of the Volga caused a panic throughout Europe and most European governments sent special commissions to the spot. The British commissioners were Surgeon-Major Colvill and Dr. J. F. Payne, who, like all the foreign commissioners, arrived when the epidemic was over. In the opinion of Dr. Payne the real beginning of the disease was in the year 1877, in the vicinity of Astrakhan, and the sudden development of the malignant out of a mild form of the disease was no more than had been observed in other places.

Plague in India.—It used to be held as a maxim that plague never appeared east of the Indus; nevertheless it was observed during the 19th century in more than one distinct centre in India. So long ago as 1815 the disease appeared in Guzerat, Kattywar and Cutch, "after three years of severe famine." It reappeared early next year, in the same locality, when it extended to Sind as far as Hyderabad, and in another direction south-east as far as Ahmedabad and Dhollerah. But it disappeared from these parts in 1820 or early in 1821, and was not heard of again till July 1836, when a disease broke out into violence at the town of Pali in Marwar in Rajputana. It spread from Pali to the province of Meywar, but died out spontaneously in the hot season of 1837.

In 1823 (though not officially known till later) an epidemic broke out at Kedarnath in Garhwal, a sub-district of Kumaon on the south-west of the Himalayas, on a high situation. In 1834 and 1836 other epidemics occurred, which at last attracted the attention of the government. In 1849–1850, and again in 1852, the disease raged very severely and spread southward. In 1853 Dr. Francis and Dr. Pearson were appointed a commission to inquire into the malady. In 1876–1877 another outbreak occurred. The symptoms of this disease, called *maha murree* or *mahamari* by the natives, were precisely those of oriental plague. The feature of blood-spitting, to which much importance had been attached, appeared to be not a common one. A very remarkable circumstance was the death of animals (rats, and more rarely snakes) at the outbreak of an epidemic. The rats brought up blood, and the body of one examined after death by Dr. Francis showed an affection of the lungs.

History Since 1880.—In 1880 plague existed or had existed within ten years, in the following parts of the world: (1) Benghazi, Africa; (2) Persian Kurdistan; (3) Irak, on the Tigris and Euphrates; (4) the Asīr country, western Arabia; (5) on the lower Volga, Russia; (6) northern Persia and the shores of the Caspian; (7) Kumaon and Garhwal, India; (8) Yunnan and Pakhoi, China.

The most striking feature of the early history of plague is the gradual retrocession of plague from the west, after a series of exceedingly destructive outbreaks extending over several centuries, and its disappearance from Europe. Western countries were the first to be freed from its presence, namely, England, Portugal and Spain. From all these it finally disappeared about 1680, at the close of a period of pandemic prevalence. Northern and central Europe became free about 1714, and the south of France in 1722. The last outbreak in northern Russia occurred in 1770. After this plague only appeared in the south-east of Europe, where in turn it gradually died away during the first half of the 19th century. In 1841 its long reign on this continent came to an end with an isolated outbreak in Turkey. From that time until quite recently it remained extinct, except in the East. The province of Astrakhan, where a very small and limited outbreak occurred in 1878, is politically in Europe, but geographically it belongs rather to Asia. And even in the East plague was confined to more or less clearly localized epidemics; it showed no power of pandemic diffusion. In short, if we regard the history of this disease as a whole, it appears to have lost such power from the time of the Great Plague of London in 1665, which was part of a pandemic wave, until the present day. There was not merely a gradual withdrawal eastwards lasting nearly two hundred years, but the outbreaks which occurred during that period, violent as some of them were, showed a constantly diminishing power of diffusion and an increasing tendency to localization. The sudden reversal of that long process is therefore a very remarkable occurrence. Emerging from the remote endemic centres to which it had retreated, plague has once more taken its place among the zymotic diseases with which modern science has to reckon.

Diffusion.—Visitations of cholera can be traced definitely to a point of origin often in India. (*See* CHOLERA.) Similarly, though not with equal precision, a wave of influenza was shown to have started from central Asia in the spring of 1889, to have travelled through Europe from east to west, to have been carried thence across the sea to America and the Antipodes, until it eventually invaded every inhabited part of the globe (*see* INFLUENZA). In both cases no doubt remains that the all-important means of dissemination is human intercourse. The movements of plague cannot be followed in the same way. With regard to origin, several endemic centres are now recognized in Asia and Africa, namely, (1) the district of Assyr in Arabia, on the eastern shore of the Red Sea; (2) parts of Mesopotamia and Persia; (3) the district of Garhwal and Kumaon in the North-West Provinces of India; (4) Yunnan in China; (5) East and Central Africa. The last was discovered by Dr. Koch.

The following is a list of countries in which plague is known to have been present in each year (*see* Local Government Board's Reports): 1880, Mesopotamia; 1881, Mesopotamia, Persia and China; 1882, Persia and China; 1883, China; 1884, China and India (as *mahamari*); 1885, Persia; 1886, 1887, 1888, India (as *mahamari*); 1889, Arabia, Persia and China; 1890, Arabia, Persia and China; 1891, Arabia, China and India (as *mahamari*); 1892, Mesopotamia, Persia, China, Russia (in central Asia); 1893, Arabia, Persia, China, Japan, Russia, East Africa, Madagascar and China and India (as *mahamari*); 1895, Arabia and China; 1896, Arabia, Asia Minor, China, Japan, Russia and India (Bombay); 1897, Arabia, China, Japan, India, Russia and East Africa; 1898, Arabia, Persia, China, Japan, Russia, East Africa, Madagascar and Vienna; 1899, Arabia, Persia, China, Japan, Mesopotamia, East Africa, West Africa, Philippine Islands, Straits Settlements, Madagascar, Mauritius, Réunion, Egypt, European Russia, Portugal, Sandwich Islands, New Caledonia, Paraguay, Argentine, Brazil: 1900, to the foregoing should be added Turkey, Australia, California, Mexico and Glasgow; in 1901, South Africa

and in 1902 Russia, chiefly at Odessa.

In 1896 plague appeared in the city of Bombay; the infection spread gradually and slowly at first, but during the first three months of 1897 not only was the town of Bombay severely affected, but district after district in the presidency was attacked, notably Poona, Karachi, Cutch Mandvi, Bhiwandi and Daman. The following figures give the mortality for Bombay and Bengal, as well as the total mortality in India.

Year	Bengal Presidency (including Calcutta)	Bombay Presidency (including Bombay City)	All India
1896	.	2,219	2,219
1897		47,710	47,974
1898	219	86,191	89,265
1899	3,264	96,592	102,369
1900	38,412	33,196	73,576
1901	78,629	128,259	236,433
1902	32,967	184,752	452,655
1903	65,680	281,269	684,445
1904	75,438	223,957	938,010
1905	126,084	71,363	940,821
1906	59,619	51,525	300,355

In 1900, there was an outbreak of plague in Australia. The total number of cases reported in Queensland was only 123, with 53 deaths. In Sydney there were 303 cases, with 103 deaths, a case mortality of 34%. The infection is supposed to have been brought from Noumea, in New Caledonia, where it was present at the end of 1899. Plague in Glasgow was on a still smaller scale. It began, so far as could be ascertained, in August 1900, and during the two months it lasted there were 34 cases and 15 deaths. Once more the disease was not at first recognized, and its origin could not be traced. In 1901 plague invaded South Africa, and obtained a distinct footing both at Cape Town and Port Elizabeth. The total number of cases down to July was 760, with 362 deaths; the number of Europeans attacked was 196, with 68 deaths, the rest being natives, Malays, Indians, Chinese and negroes. With regard to Great Britain, a few ship-borne cases had to be dealt with at the ports.

Causation.—Plague is a specific infectious fever, caused by the *bacillus pestis*, which was identified in 1894 by Kitasato, and subsequently, but independently, by Yersin (*see* BACTERIA and DISEASE). It is found in the buboes in ordinary cases, in the blood in the so-called "septicaemic" cases, and in the sputum of pneumonic cases. It may also be present in the urine. *Post mortem* it is found in great abundance in the spleen and liver. Nothing is known of its natural history outside the body, but on cultivation it is apt to undergo numerous involution forms. Its presence in a patient is regarded as positive diagnostic proof of plague; but failure to find or to identify it does not possess an equal negative value, and should not be too readily accepted. It is quite clear, from the extreme variations in the severity of the illness, that the resisting power of individuals varies greatly. According to the Plague Research Committee of Bombay, the predisposing causes are "those leading to a lower state of vitality," of which insufficient food is probably the most important. There is no evidence that age, sex or race exercises a distinct predisposing influence. The largest incidence in Bombay was on young adults; but then they are more numerous and more exposed to infection, because they go about more than the younger and the older. Similarly, the comparative immunity of Europeans in the East may be explained by their different conditions of life. It is doubtful whether the distinction drawn between *pestis minor* and *pestis major* has a real aetiological basis. Very mild cases occurring in the course of an outbreak of typical plague may be explained by greater power of resistance in individuals, but the epidemic prevalence of a mild illness preceding the appearance of undoubted plague suggests some difference or modification of the exciting cause. Of course plague does not stand alone in this respect. Epidemic outbreaks of other diseases—for instance, cholera, diphtheria and typhoid fever—are often preceded and followed by the prevalence of mild illness of an allied type.

Clinical Characters.—One of the results of recent observation is the classification of plague cases under the three heads: (1) bubonic, (2) pneumonic, (3) septicaemic. This classification is a clinical one, and the second and third varieties are just as much plague as the first. It is necessary to say this, because a misleading use of the word "bubonic" has given rise to the erroneous idea that true plague is necessarily bubonic, and that non-bubonic types are a different disease altogether.

The illness varies within the widest limits, and exhibits all gradations of severity, from a mere indisposition, which may pass almost unnoticed, to an extreme violence, only equalled by the most violent forms of cholera. The mild cases are always bubonic; the other varieties are invariably severe, and almost always fatal. Incubation is generally from four to six days, but it has been observed as short as thirty-six hours and as long as ten days (Bombay Research Committee). As a rule the onset is sudden and well marked.

(1) Bubonic cases usually constitute three-fourths of the whole, and the symptoms may therefore be called typical. In a well-marked case there is usually an initial rigor—in children convulsions—followed by a rise of temperature, with vomiting, headache, giddiness, intolerance to light; pain in epigastrium, back and limbs; sleeplessness, apathy or delirium. The headache is described as splitting; delirium is of the busy type, like delirium tremens. The temperature varies greatly; it is not usually high on the first day—from 101° to 103°—and may even be normal, but sometimes it rises rapidly to 104° or 105° or even 107° F; a fall of two or three degrees on the second or third day has frequently been observed. The eyes are red and inflamed; the tongue is somewhat swollen, and at first covered with a thin white fur, except at the tip and edges, but later it is dry, and the fur yellow or brownish. Prostration is marked. Constipation is the rule at first, but diarrhoea may be present, and is a bad sign. A characteristic symptom in severe cases is that the patient appears dazed and stupid, is thick in speech, and staggers. The condition has often been mistaken for intoxication. There is nothing, however, in all these symptoms positively distinctive of plague, unless it is already prevalent. The really pathognomonic sign is the appearance of buboes or inflamed glands, which happens early in the illness, usually on the second day; sometimes they are present from the outset, sometimes they cannot be detected before the third day, or even later. The commonest seat is the groin, and next to that the axilla; the cervical, submaxillary and femoral glands are less frequently affected. Sometimes the buboes are multiple and on both sides, but more commonly they are unilateral. The pain is described as lancinating. If left, they usually suppurate and open outwards by sloughing of the skin, but they may subside spontaneously, or remain hard and indurated. Petechiae occur over buboes or on the abdomen, but they are not very common, except in fatal cases, when they appear shortly before death. Boils and carbuncles are rare.

(2) Pneumonic plague was observed and described in many of the old epidemics, but its precise significance was first recognized by Childe in Bombay. He demonstrated the presence of the bacilli in the sputa, and showed that the inflammation in the lungs was set up by primary plague infection. The pneumonia is usually lobular, the onset marked by rigors, with difficult and hurried breathing, cough and expectoration. The prostration is great and the course of the illness rapid. The breathing becomes very hurried—forty to sixty respirations in the minute—and the face dusky. The expectoration soon becomes watery and profuse, with little whitish specks, which contain great quantities of bacilli The temperature is high and irregular. The physical signs are those of broncho-pneumonia; oedema of the lungs soon supervenes, and death occurs in three or four days.

(3) In septicaemic cases the symptoms are those of the bubonic type, but more severe and without buboes. Prostration and cerebral symptoms are particularly marked; the temperature rises rapidly and very high. The patient may die comatose within twenty-four hours, but more commonly death occurs on the second or third day. Recovery is very rare.

The case mortality of plague still remains exceedingly high. The lowest recorded is 34% in Sydney, and the highest 95% at

Hong Kong in 1899. During the first few weeks in Bombay it was calculated by Dr. Viegas to be as high as 99%. It is very much higher among Orientals than among Europeans. In the Bombay hospitals it was about 70% among the former, and between 30% and 40% among the latter, which was much the same as in Oporto, Sydney and Cape Town. It appears, therefore, that plague is less fatal to Europeans than cholera. The average duration of fatal cases is five or six days; in the House of Correction at Byculla, where the exact period could be well observed, it was five and a half days. Patients who survive the tenth or twelfth day have a good chance of recovery. Convalescence is usually prolonged. Second attacks are rare, but not unknown.

Diagnosis.—When plague is prevalent in a locality, the diagnosis is easy in fairly well-marked cases of the bubonic type, but less so in the other varieties. When it is not prevalent the diagnosis is never easy, and in pneumonic and septicaemic cases it is impossible without bacteriological assistance. The earliest cases have hardly ever been even suspected at the time in any outbreak in a fresh locality. It may be taken at first for almost any fever, particularly typhoid, or for venereal disease or lymphangitis. In plague countries the diseases with which it is most liable to be confounded are malaria, relapsing fever and typhus, or bronchopneumonia in pneumonic cases.

Dissemination.—The investigations of the Indian plague commission working in conjunction with the advisory committee showed that bubonic and septicaemic plague are transmitted by the agency of fleas. Highly susceptible animals are not infected by their plague-stricken fellows so long as fleas are excluded from the cages, but with the introduction of these ectoparasites the disease forthwith spreads from the sick to the healthy. Subsequent experience has confirmed the main findings of the commission, and outbreaks of human plague are unquestionably mere extensions of preceding or concurrent plague affecting animals. Rats (*Rattus rattus*) are of outstanding importance as reservoirs of infection through their close association with man, but marmots (*Arctomys bobac*), gerbilles (*Tatera lovengulae*) and ground squirrels (*Citellus beecheyi*) have been responsible for epidemic outbreaks in China, South Africa and California respectively.

The plague commission concluded that the disease can be transmitted by the faeces of infected fleas, but did not state that this is the usual method of spread. Bacot and Martin later demonstrated that the entrance to the flea's stomach becomes obstructed by a mass of plague bacilli. Such fleas in their persistent efforts to feed merely succeed in distending the gullet with blood, which, now contaminated, regurgitates on to the skin of the host. The organisms then enter the body either through the flea's bite or through some abrasion of the skin.

The flea most commonly incriminated as a plague-vector is *Xenopsylla cheopis*, but several other species of rat fleas (*Ceratophyllus fasciatus, Stivalius ahalae*), the common mouse flea (*Leptopsylla musculi*), the dog flea (*Ctenocephalus canis*), a marmot flea (*Ceratophyllus silantievi*) and the human flea (*Pulex irritans*), amongst others, are proven carriers of plague.

Epidemiology.—Laborious studies on the biology of fleas have added to our knowledge of the epidemiology of plague. These insects cannot withstand desiccation, and their survival apart from their host is proportional to the rate at which they lose moisture. Bacot and Martin (1924) found the water content of fleas to be 80% of their weight, and death occurred before the loss of water had reached 60% of their weight. This goes far to explain the observation that plague does not maintain itself in epidemic form when the temperature rises above 80° F, accompanied by a saturation deficiency of over ·30 of an inch.

The seasonal variations in the spread of plague have been recognised for many centuries. In temperate countries epidemics attain their maximum in the summer months, whereas in tropical climates the onset of hot, dry weather brings an existing epidemic to an end. In each case, the peak of the plague curve coincides with meteorological conditions most favourable to the activity and longevity of fleas. In contradistinction to the foregoing, pneumonic plague, once established, spreads independently of animals and fleas. In outbreaks of ordinary plague, a secondary involvement of the lungs supervenes in a small proportion of cases, and if atmospheric and environmental conditions favour the survival and transmission of the bacilli an epidemic of pneumonic plague may result, the virus being transmitted from the cougher to the victim up to a range of about three feet.

Treatment and Prophylaxis.—Unfortunately, there is no plague specific. Serum, to be really effective, must be given before the symptoms of the disease are manifest, an impossible procedure in most cases. Still, when available, serum should be administered intravenously in doses of 80–100 c.c.'s, and repeated. Some advocate injection of tincture of iodine (7–10 minims), or other antiseptics, intravenously, and also into the buboes. These measures are of doubtful benefit. Buboes showing signs of suppuration should be incised. Otherwise, treatment is on general lines, and cardiac stimulants should be administered early.

So long as members of a community are content to live in association with rats and fleas correlative plague is a likely result. Meanwhile, plague prophylaxis consists mainly of warfare against rats, in the hope of ultimately banishing them from human habitations and from contact with man. Any general elimination of these pests over wide areas is a slow, costly and usually impracticable affair, and all that can be achieved in most cases is some degree of palliation by rat-proofing of grain stores, wharves and other places which serve as centres for the dissemination of plague. Destruction of rats by trapping and poisoning is a commendable procedure, but of itself will never eradicate endemic plague, for the losses in the rat population are quickly made good if survivors are provided with food and harbourage. An important measure of personal prophylaxis is inoculation with anti-plague vaccine, which affords a good degree of protection. Persons entering plague-infected houses should wear gaiters, and otherwise render their clothing as flea-proof as possible; if there is any suspicion of pneumonic plague, goggles, and masks made of several layers of fine gauze, should be worn without fail.

PLAICE (*Pleuronectes platessa*), a flat-fish that ranges from Iceland and northern Europe to south of Great Britain, and one of the most important commercial fishes of the North sea. Other species of somewhat similar form, with large eyes on the right side and with a small terminal mouth, are the dab and flounder; from these the plaice is easily distinguished by the red spots scattered over the body. The pharyngeal bones are strong and bear large blunt teeth, used for crushing the shells of the bivalves that are the principal food of this species. A length of more than 30 in. and a weight of 8 lb. may be attained, but nearly all the fish marketed are less than half that length.

PLAINFIELD, a city of Union county, New Jersey, U.S.A., 24 m. W. by S. of New York city; served by the Baltimore and Ohio, the Central of New Jersey and the Reading railways. Pop. (1920) 27,700 (20% foreign-born white and 9% negro). With the adjacent boroughs of North Plainfield and South Plainfield, the population of "the Plainfields" was estimated locally at 49,500 in 1928. Situated on high ground among the charming Watchung hills, well laid out and strictly zoned, Plainfield is one of the most attractive of the residential suburbs of New York. There are five golf courses in and near the city, clubs devoted to various sports and recreations, a symphony orchestra, a community playhouse and excellent public and private schools. While manufacturing is relatively unimportant, there are substantial industries and the aggregate output in 1925 was valued at $16,972,652. The city's

assessed valuation for 1928 was $55,545,725. Settlement here dates from 1684. In 1760 a grist-mill was erected, and for several years the village was called Milltown. The township of Plainfield was created out of the township of Westfield in 1847 and in 1867 the city was chartered.

PLAINS INDIANS. The tribes of the central portion of the North American continent, on the open plains and parkland prairies extending from Alberta and Saskatchewan to Texas and from the Rocky Mountains almost to the Mississippi river, formed a natural unit, both in environment and culture. Essentially, this territory is the habitat of the American bison (buffalo); and on this animal the Plains tribes primarily depended for food, shelter, clothing and many utensils, and to its habits many of their customs were adapted. The eastern tribes, in the prairies, seasonally combined bison hunting and maize farming; the western ones, in the plains proper, were wholly nomadic. Originally, they transported their tents and belongings on travois frames dragged by dogs. After the introduction of the horse by the Spaniards, beginning about 1650, this animal gradually replaced the dog, tribal movements became freer, while their numbers augmented and their culture elaborated. They camped in large circles of tepees, conical tents of bison skins supported by long poles leaning on a primary tripod (or four poles)—a highly specialized, convenient dwelling quickly pitched and struck. Cooking was by roasting, or with hot stones in bison rawhide containers; meat predominated heavily in the diet. Property and food were stored and transported in rawhide bags and "parfleches." Clothing was of deer (antelope, elk) skins, supplemented by bison robes, and was well tailored, ample, comfortable, and often highly ornamented with embroidery of porcupine quills, later beads. Social organization was simple: matrilinear clans, patrilinear clans, or non-exogamic bands, according to tribe. Warfare was constant, being carried on partly for profit (horse raiding) but chiefly for honour, a man's career depending directly on the prestige of his war exploits; hence arose the system of "counting coups," that is, publicly recounting blows struck on enemies. The best known ritual was the so-called Sun dance. Most other rites were conducted by societies, which among some tribes were age-graded. Supernatural power was sought in visions by most men, warriors as well as curers. There were sacred "bundles" for tribes, clans and societies; these were fetiches preserved for generations.

The Plains tribes are proud, brave, out-spoken and direct, and possess an unusual sense of individuality and personality. The physique is exceptionally tall, rangy and hardy. With their long braided hair, fringed costume, eagle feather war-bonnets, mounted on ponies, with tepees as a background, the Plains tribes have captured the imagination of recent generations of whites; and pass popularly as the most representative of Indians. The most typical Plains tribes are the Dakota, Assiniboine, Blackfeet, Gros Ventre, Arapaho, Cheyenne, Kiowa, Comanche; others are the Sarsi, Plains Cree, Plains Ojibwa, Wind River Shoshone, Mandan, Hidatsa, Arikara, Pawnee, Omaha, Ponca, Iowa, Oto, Missouri, Kansas, Osage, Wichita, Kiowa Apache; and, among the tribes in or across the Rocky mountains, the Kootenay, Flathead, Nez Percé, Bannock, Ute and Jicarilla Apache have been especially influenced by Plains culture. The preponderant stock is the Siouan; next, the Algonkin; Shoshonean, Athabascan, Caddoan are also each represented by two or more tribes.

See C. Wissler, "Indians of the Plains" (*Am. Mus. Nat. Hist.*, 1912) for a general summary; and monographs or books by G. Catlin, W. P. Clark, E. H. Curtis, G. A. Dorsey, J. O. Dorsey, A. C. Fletcher, G. B. Grinnell, A. L. Kroeber, F. La Flesche, Lewis and Clark, R. H. Lowie, Maximilian (Prince zu Wied), W. McClintock, J. Mooney, J. Murie, S. Riggs, J. W. Schultz, L. Spier, C. Wissler. (A. L. K.)

PLAINSONG or PLAIN CHANT. A general term for a certain style of unisonal music, comprising chiefly the church-music called "Gregorian" which belongs to Rome, and that called "Ambrosian" which hails from Milan. But the other Western collections of church-music, much less well-known than these, and a good many groups of Eastern church-music could also quite properly be put under this heading.

Origin.—There are various factors in the genesis of music which determine its essential characteristics. Music intended for a dance is necessarily regular in its rhythm; so also, though less tied, is music which is set to metrical verse. On the other hand music fitted to a prose text is not so regular. Thus there arise different kinds of rhythm in music, ranging from strict time to the freest of movement. Again some music arises from recitation and the need to declaim some words artistically and audibly; while other music aims at melody, that is to say a succession of sounds, which is pleasant for its own sake, and would be so independently of any words.

The ecclesiastical music which is called plainsong is so named because it is unmeasured music, not regular in rhythm, a *cantus planus* as contrasted with *cantus mensurabilis* or measured music. It is this feature that chiefly differentiates it from modern music; and at the same time allies it with such things as sea-chanties, counting-out rhymes, and the like. The Christian church, like other worshipping bodies, requires euphonious sounds for the recitation of its psalms, and for the reading of its scriptures in public. As these passages are not (for the most part) written in any strict metre, the music to be provided is essentially a "plain" chant; there are several classes of such plainsong.

Influence of the Psalter.—The chief influence in this evolution has been that of the Psalter. Hebrew poetry follows a metrical system, but this disappears in translation. There survives however, a more obvious feature of the original, viz., its parallelism. This consequently becomes a prominent characteristic of certain sorts of plainsong, so that the chants directly derived from the psalms take a binary form. The recitation demands a reciting note, on which the text can be freely recited in its own rhythm and shape. If this note alone is used, the effect soon becomes, in the strict sense of the word, monotonous. Therefore the music adopts the natural tendency of the voice to rise up to its reciting note at the beginning and to drop down from it at the end of the phrase. Thus arises the commonest chant-form of plainsong, consisting of (1) an intonation, (2) recitation, and (3) cadence, in each half-verse. The psalm-tones whether Gregorian or Ambrosian take this shape; and the form is capable of more or less elaboration for the psalms. The Gregorian tones are very simple; more elaborate forms of them are used for the Gospel-canticles; and still more developed forms for the Introits. A limit is naturally set to the amount of elaboration either (a) when whole psalms are to be sung at length, or (b) when they are to be sung by the whole congregation. When, however, select verses only are sung, and are sung by trained singers, there is far more scope for elaboration; and the developed responds used both at Mass and at the Choir-office exhibit this chant-form in a highly ornamental shape.

The chief development occurs in the Cadences. In its simplest form the musical cadence affects only the last syllable, *e.g.* there is the drop of a minor third. Next it concerns the last two syllables. These two simple cadences are familiar, even to those who do not know the Gregorian tones, from their being used in the Versicles and Responses of the Prayer Book. The more elaborate cadences naturally followed the "cursus" used by Latin prose-writers of the best, or at any rate, the most formal, style. In the responds a five-syllable cadence is constantly in use, and often in a highly decorated form.

All this music arises out of the recitation of psalms. For the purpose of declaiming the lessons of Scripture only the simpler inflexions were used; and the same is true of the prayers or collects, except a few which are of exceptional solemnity such as the "Preface" or the Lord's Prayer, as used in the consecration prayer at Mass; or the Hallowing of the Font at Baptism.

Antiphons.—Next to be considered is a totally different way of beautifying the recitation of psalms or other prose texts. Instead of elaborating the chant itself there was interpolated between the verses a suitable refrain. These refrains came to be known as "antiphons": and thus side by side with the older method, which came to be called "responsorial" from the responds which represented it at its fullest development, there arose the newer "antiphonal" method. The former music developed from recitation, and even in its most elaborate forms in more or less degree it hung round a reciting note. The antiphons were purely melodic and the method had its quality and meaning determined.

not by reference to a "dominant" reciting-note, but to the "final" note on which it ultimately came to rest.

Antiphonal music underwent modification and development just as the responsorial music did. Its relation to the psalm altered; the singing of the refrain after each verse survived mainly in processional use. In choir offices the refrain was dropped so that it was sung only at the beginning and end of the psalm, or else in a curtailed form at the beginning and in full only at the end. In the psalmody of the Mass the opposite form of abbreviation was adopted. For at the Introit and the Communion the psalm became restricted to only one or two verses, and at the Communion it ultimately disappeared altogether, leaving the Antiphon alone.

Some antiphons composed on a large scale arose independently of any connection with a psalm. These were used especially in processions. Others retained the idea of a psalm-verse, but utilized for such verses not the normal psalm-tones, but independent melodies, perhaps as elaborate as the psalm itself. Such antiphons especially prevailed at the Offertory in the Mass.

The greater part of the classical Gregorian plain-chant falls into one or other of these two classes. The amount of elaboration depended mainly upon two considerations (1) the importance of the occasion; and (2) the capacity of the singers. A great festival or a specially dignified part of the service demanded richer treatment: and the trained singers undertook more difficult music than the congregation, the soloists than the choir generally.

The Gregorian Music.—The *Cantilena Romana*, Gregorian chant proper, is thus a body of music, purely vocal and ecclesiastical, evolved by the Papal choir in the course of the fifth and sixth centuries. This was codified in the time of St. Gregory (*c.* 540–604) (*q.v.*) and it stands as the basis of all the Gregorian Music. The Milanese tradition was similar but less artistic. It is called "Ambrosian" (*see* St. Ambrose) but the term has no historical significance as the term Gregorian has. A comparison of these two families of plain-chant brings out clearly the comparative crudity of the Ambrosian tradition as distinct from the artistic balance and delicate finish of the classical Gregorian chant. The same is true also of such other specimens of Western ecclesiastical chant as are known. The Gregorian reform marks the close of a golden age of classical monody. The middle-ages subsequent to St. Gregory produced nothing so good; and the later part of them while producing only little and decadent plainsong depraved also the form of the classical tradition.

Something more must be said to describe the contents of the Gregorian *corpus* and also to explain the musical theory which lay behind it. The music covers the whole set of services of the Roman rite, but principally the Mass and the series of daily Choir Services. At the Mass some of the things sung are invariable, while others change according to the Sunday, or Festival, or occasion generally. The unchanging elements are chiefly the *Kyrie, Credo, Sanctus, Agnus dei,* and *Gloria in excelsis.* For these the old tradition provided little or no change of music; and what there was followed very simple lines suitable for congregational singing. The variable elements were principally the Introit-psalm, the Gradual-respond, the Offertory-antiphon and the Communion-antiphon. The Gradual was at times replaced or supplemented by an Alleluia with a Verse attached to it, or by a Tract. The Alleluia belonged specially to festive seasons and occasions, the Tract to penitential. Neither of these falls exactly into either of the two chief categories responsorial and antiphonal. The Tract is a very ancient but elaborate type of the developed psalmody; the Alleluia was an innovation which came in towards the end of the classical period, and extended beyond it into the "Silver Age" when little else was being composed.

For the choir-offices there was provided a large number of antiphons to go with the psalmody, and a considerable number of responds which mainly served as interludes between the lessons at Mattins. When hymnody began with St. Ambrose it was taken up and incorporated into the services by the monks; but Rome was for a long time too conservative to admit hymns. The plainsong hymn-tunes are, in the nature of the case, more definitely metrical than the other music: but they retain a considerable freedom of movement, and are not "measured," like modern hymn-tunes.

Underlying Musical Theory.—The musical theory which lies behind this music is based on a series of eight scales or Modes. It uses the old diatonic scale of the Greek theorists (equivalent to the white notes of the pianoforte with the addition of B), but the modes themselves are different from the old Greek modes, and the use of the old Greek names only leads to confusion. The eight-mode system was probably the same as the ὀκτόηχος which underlies the Eastern church music; but the origins are obscure alike in East and West. The scheme seems to go back at least to St. John of Damascus (*c.* 750); but it is known in the West only in theoretical treatises derived through the Byzantine teachers at the court of Charlemagne at the end of the eighth century.

The eight modes are really four pairs, each pair being founded on the same note, the one scale (called Authentic Mode) being an octave ranging above the foundation or final note, the companion (called Plagal) being an octave ranging above and below it.

First / Second	A BCD EF G a bc d
Third / Fourth	BC D EF G a bc d e
Fifth / Sixth	C D EF G a bc d ef
Seventh / Eighth	D EF G a bc d ef g

Each of these pairs has a character or tonality of its own, dependent upon the position which the semitones have in the scale. None is similar to the major or minor key of modern music. It is this tonality which gives the special character to plain-song melody. Some theorists have reckoned twelve or even fourteen Modes; but this is unnecessary. So far as pitch goes, the range of two octaves covered by the eight modes is adequate; and so far as tonality is concerned, the new modes would be only the same as the first four or six over again with the B♭ used instead of B. (For further discussion of the Modes *see* Harmony.)

This modal theory does not fully account for all the procedure of the classical plain-chant (practice always surpasses theory): but these eight modes are clearly the foundation of this music, whether responsorial or antiphonal.

In the middle ages the *cantilena Romana* was handed on by tradition from St. Gregory's days; in the ninth century it was recorded in the notation reames. The notation on a staff which began a couple of centuries later, while it fixed accurately the pitch of each note, failed to reproduce the rhythmical delicacies which the earlier notation had recorded. Hence the recent renascence of classical plain-song has been based on a return to the reames, as interpreted by the subsequent tradition.

The revived interest in music of the Carolingian era stimulated composition, which had been long in abeyance. Not only new music for new feasts arose, but fresh settings of the "Ordinary" (fixed elements) of the Mass. While the old music was preserved, it was padded out with new and inferior interpolations called by the generic name of "Tropes." These had their day and pervaded all the church music for a century or more; but then they went out of fashion, leaving only two considerable legacies, (a) a further series of settings of the "Ordinary," (b) the new form of rhythmical, or (later) metrical, poem called Sequences or Proses. These survived in considerable numbers down to the sixteenth century, but at the present time only a few are in use.

Modern Revival.—The rise of the art of harmony beginning from the eleventh century, diverted attention from the monody of plain-chant, and part-singing had the effect of "measuring" the music so that it fell into regular time and was no longer free or "plain." Under these influences the old plain-song was progressively debased and as harmonized music went up, plain chant went down. Not until the nineteenth century did this degradation cease. The efforts then made in various quarters to recover alike the true rhythm and tonality of the old music have culminated in the work of the Benedictines of Solesmes and their

followers, and in the revival which has produced the new Vatican Gradual and is producing by degrees a restored Antiphonal as well. With the recovery of the music has come a new insistence upon its use and study, as being the official music of the Roman Church. (W. H. F.)

PLAINTIFF: *see* PRACTICE AND PROCEDURE.

PLAINVIEW, a city of north-western Texas, U.S.A., 270 m. W. by N. of Fort Worth, on the south plains of the "Panhandle" at an altitude of 3,370 ft.; the county seat of Hale county. It is on Federal highways 70 and 385, and is served by the Santa Fe and the Colorado and Southern railway systems. Pop. (1920) 3,989; estimated locally at 10,000 in 1928. It is the trade centre of 5,000 sq.m. of farming territory (partly irrigated) raising chiefly cotton, wheat and grain sorghums. The Texas Panhandle Plains Dairy Show is held here annually. The site for the city was surveyed in 1887. The settlement remained a mere trading post for the cattlemen who then occupied the entire region until the railway reached it in 1907, whereupon it was incorporated as a city. By 1927 it had an assessed valuation of $6,443,061. Diversified farming began to displace ranching about 1915, and the cultivation of cotton began in 1918.

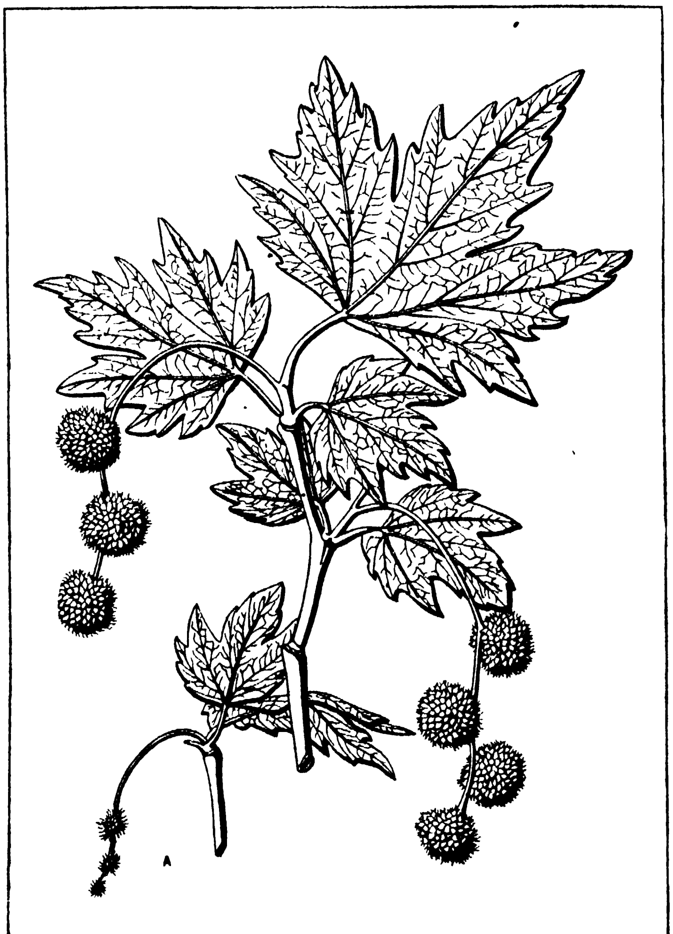
PLANCK, MAX (1858–), German physicist, was born at Kiel on April 23, 1858. He studied at the universities of Munich and Berlin, became an assistant in Munich University, and was subsequently appointed a professor in Kiel (1885) and in Berlin (1889). Planck devoted himself to the study of theoretical physics, and in particular to that of thermodynamics. His lectures on this subject appeared in book form and were translated into English, French and Russian. He gained international fame by his *Law of Radiation* (1901), which asserts that the energy of radiation is emitted and absorbed in integral multiples of certain indivisible "quanta" of energy, which depend on the frequency of oscillation of the electrons. In 1912 Planck extended this "quantum theory" (*q.v.*) to all kinds of energy and added the assumption that only emission proceeds discontinuously, in quanta, while absorption is continuous. On this assumption he was able to derive the distribution of energy in the spectrum of black-body radiation. The quantum theory has been developed and modified by him and many other physicists but the foundation was laid by Planck's work on black-body radiation. In 1918 he was awarded the Nobel Prize for physics. Planck became editor of the *Annalen der Physik*. He was elected a foreign member of the Royal Society in 1926.

Among his works are: *Die Entstehung und bisherige Entwickelung der Quantentheorie* (1920, Eng. trans. 1922); *Vorlesungen über die Theorie der Wärmestrahlung* (1921); *Physikalische Rundblicke* (1922, Eng. trans. 1925); *Einführung in die Theorie der Elektrizität und des Magnetismus* (1922); and *Die Ableitung des Strahlungsgesetzes* (1923).

PLANE. The simplest definition of plane given by the Greek geometers is that of Heron of Alexandria (*c.* 200):—a surface "such that if a straight line passes through two points on it, the line coincides wholly with it at every spot, all ways." Crelle (1834) defined it as the surface containing all the straight lines (throughout their entire lengths) passing through a fixed point and also intersecting a straight line in space. (For plane, a tool, *see* EDGE TOOLS.)

See H. Schotten, *Inhalt und Methode des planimetrischen Unterrichts* (Leipzig, 1890, 1893); Sir T. L. Heath, *The Thirteen Books of Euclid's Elements* (1926). (*See* also SURFACE.)

In botany, plane is the common name of a handsome tree known botanically as *Platanus orientalis* (family Platanaceae), a native of Greece and western Asia, a favourite shade-tree of the ancient Greeks and Romans, and introduced by the latter to south-west Europe. It is one of the most successful trees in London and other large towns; the smooth face of the leaf is easily washed by rain; and the periodical peeling of the bark also serves to get rid of surface deposits of soot, etc. It is a large tree with widely spreading branches and alternate, palmately five-lobed leaves, resembling those of the sycamore in shape, but quite hairless and of a brighter green. The bud in the leaf axil is protected during its development by the hollow base of the leaf-stalk, which lifts off like an extinguisher when the leaf falls in autumn. The minute, unisexual flowers are borne in dense pendulous heads, which contain either male or female flowers; the small one-seeded fruits are densely crowded in a ball, from which they gradually separate in drying, and are readily carried by the wind. A variety of forms are known in cultivation, the commonest being the maple-leaved (*acerifolia*), the London plane, which has usually three-lobed leaves; var. *laciniata* has very deeply much divided leaves, and var. *variegata*, variegated foli-



PLANE (PLATANUS ORIENTALIS), SHOWING BRANCH WITH FRUITS. A. BRANCH WITH DROOPING FEMALE HEADS WHICH ARE WIND POLLINATED

age. *Platanus occidentalis,* an allied species, is a native of the United States, being most abundant and growing to its largest size in the basin of the lower Ohio and the Mississippi rivers It was introduced into England early in the 17th century, and is occasionally met with in western and central Europe; it is known in America as sycamore and buttonwood. It differs from *P. orientalis* in its less deeply lobed, more leathery pubescent leaves and in the usually solitary balls of fruit. Both the native sycamore and the London plane are extensively planted as ornamental trees in the eastern United States. The California sycamore (*P racemosa*) and the Arizona sycamore (*P. Wrightii*), of the extreme South-west, are much smaller than the eastern species.

PLANER: *see* MACHINE TOOLS; WOODWORKING MACHINERY

PLANET (Gr. πλανήτης, a wanderer). The term was applied in the ancient Ptolemaic or geocentric astronomy to the seven heavenly bodies which were observed to change their places as projected against the background of the so-called fixed stars. These bodies were the Sun, the Moon, Mercury, Venus, Mars, Jupiter and Saturn, all of which were supposed to revolve round the earth In the modern or heliocentric astronomy (taught by Aristarchus of Samos in the third century B.C. but forgotten or neglected till revived by Copernicus in the 16th century of the Christian era) it is applied to all dark and opaque bodies in revolution round the sun, and the number of such bodies known has been greatly increased by successive discoveries. In 1781 William Herschel discovered Uranus. In 1801, on the first night of the new century,

*In mean solar days and tropical years.

Piazzi discovered Ceres, a small planet revolving between the orbits of Mars and Jupiter and the first of a great host of small bodies known as minor planets or asteroids; while in 1846 Neptune was added to the list of major planets following on the mathematical work on the unexplained irregularities in the motion of Uranus by Le Verrier and, independently, by Adams (*see* notes on Neptune). Taken in its widest sense the term planet is also sometimes applied to the satellites attendant on the greater planets, the latter being called *primary*, and the former *secondary*, planets. Of these secondary planets or satellites, so far as at present known, Neptune possesses one, Uranus four, Saturn nine, Jupiter nine, Mars two and the Earth one. The order of the primary planets reckoning outwards from the sun is: Mercury, Venus, the Earth, Mars, Minor Planets, Jupiter, Saturn, Uranus and Neptune.

Distances of the Planets.—An empirical law expressing very closely the relative distances from the sun of the primary planets known to the ancients was discovered about the middle of the eighteenth century by Titius of Wittenburg, but it was later brought into notice by Bode and is generally known as Bode's law. If a series of 4's be written down, and 3 be added to the second, 6 to the third, 12 to the fourth and so on, each of the added numbers being double its predecessor, the sums of the first seven numbers are 4, 7, 10, 16, 28, 52, 100. These numbers divided by 10 were found to give with a surprising closeness the relative distances of the planets as far as Saturn, except that no planet was known to revolve in the orbit corresponding to 2·8 between the orbits of Mars and Jupiter. When Uranus was discovered and found to fit in well with the next number in the series (19·6) the conviction was strengthened that the gap between Mars and Jupiter must be occupied by some planet and a search for the missing body was organized. But before systematic work was actually begun the little planet Ceres was found. The discovery was soon followed by others, and at the present time considerably more than 1,000 of these minor planets are known. They are not, however, actually confined to the gap above mentioned. The little planet Eros discovered by Witt in 1898 comes at perihelion within 13,000,000 miles of the earth's orbit and hence it is of special value to astronomers for the determination of the solar parallax which fixes the scale of the planetary system. Hidalgo, discovered by Baade in 1922, in the most distant part of its orbit goes out as far as the orbit of Saturn and has a mean distance slightly greater than that of Jupiter. The actual distances of the greater planets from the sun in miles will be found in Table I.

Orbits and Phases of the Planets.—From the observations of Tycho Brahe, the great Danish observer, Kepler deduced the following three great laws of planetary motion:—

(1) The planets move in ellipses with the sun at one focus. Hitherto it had been believed that the circle being the most perfect geometrical figure celestial motions took place in circles.

(2) The straight line from the sun to a planet (radius vector) passes over equal areas in equal times. The importance of this law was that it involves a continually varying rate of motion, which was also contrary to accepted beliefs at the time. To maintain the equal description of areas in unit time a planet must travel faster in the neighbourhood of perihelion where the radius vector is at a minimum than near aphelion where it attains its maximum value.

(3) The squares of the periodic times (the times required for the orbital revolutions of the planets) are proportional to the cubes of the mean distances (the semi-major axes of their orbits). This is commonly known as the *harmonic law* and defines the relationship between a planet's orbital motion and its distance from the sun.

From these laws of planetary motion Newton deduced his law of universal gravitation which has achieved such remarkable successes and prepared the way for Einstein's relativity theory.

The dimensions, form and aspect of a planet's orbit as well as the position of the planet in the orbit at any time are defined by what are known as its *elements*. These are:—

(1) Half the major axis, or mean distance (generally denoted by α). This defines the *size* of the orbit.

(2) The eccentricity (e) or the ratio of the distance of the sun from the centre of the orbit to the mean distance. This defines the *shape* of the orbit.

(3) The inclination (i) of the orbit plane to the ecliptic, *i.e.*, to the plane of the earth's orbit.

(4) The longitude of the ascending node (☊), *i.e.*, the direction at the sun of the point on the orbit (measured from the vernal equinox or "first point of Aries") at which the planet crosses the ecliptic from its south to its north side. This defines the *aspect* of the orbit.

(5) The longitude of the perihelion (ω). This defines the direction of the major axis in the plane of the orbit.

(6) The period (P), *i.e.*, the time the planet takes for a revolution.

(7) The longitude of the planet at the epoch (L) or time (T) of the planet's perihelion passage. These elements are given for the several planets in Table I.

Since the orbits of Mercury and Venus lie within that of the earth these two planets when observed telescopically will show phases similar to those presented by the moon. When on the far side of the sun, *i.e.*, near the time of superior conjunction, each of them will appear like a small full moon. As the angle earth-planet-sun increases a proportionally diminishing fraction of the illuminated surface will be presented to view, and when the angle reaches 90° the planet will appear half illuminated like the moon at first quarter. Following this a crescent form of steadily diminishing breadth will be assumed as the planet moves towards inferior conjunction, at which point it passes between the earth and the sun. Subsequently to this the phases described will be repeated in the reverse order up to superior conjunction when the planet will again be "full." The phases of a planet revolving outside the earth's orbit differ from those of Mercury and Venus in as much as the angle earth-planet-sun can never increase to 90°. Thus Mars, although at times presenting a markedly gibbous aspect like a nine or ten days' old moon, is always more than half illuminated. In the case of Jupiter the defect of illumination is so small as to be almost imperceptible, but during the occultation of a satellite the planet's dark limb is seen across the satellite's disk, and a narrow black space separates the latter from the bright part of the planet's surface. In the cases of the planets revolving outside Jupiter the phase is quite imperceptible even in powerful telescopes. The variations in apparent diameter and brightness will,

of course, also be small in the cases of the remoter planets.

Physical Condition and Atmospheres.—There is a broad distinction between the two groups of the major planets on either side of the zone of the asteroids. The planets of the inner group are of relatively small mass and high density and possess solid surfaces. Those of the outer group, especially Jupiter and Saturn, are of much larger mass but of very low density. The density of Saturn is actually less than that of water. The masses of the planets possessing satellites are derived from the distances and periodic times of the satellites by an application of Kepler's third law. The masses of Mercury and Venus are deduced from their gravitational effect on other bodies.

There is for each of the planets a certain critical velocity determined by the force of gravity at its surface, and a particle of matter travelling at a speed in excess of this value will escape from the planet in question and revolve in an independent orbit round the sun. These critical values for the several planets are given in column 12 of Table II. Now according to the kinetic theory of gases every molecule of a gas is an independent particle and is in constant motion. Its velocity will depend on the atomic weight and the temperature and may attain to thousands of feet per second. A molecule with such a high speed in the upper part of a planet's atmosphere where it will be comparatively free from collision with other molecules cannot be retained by a body with low surface gravity but will escape into space. It might be expected, accordingly, that only the large and massive planets are enveloped in dense atmospheres, and that those of small mass and low surface gravity have atmospheres which are of greater rarity and tenuity. Observation shows that this is in general the case. The spectra of the planets of the outer group contain strongly marked absorption bands due to their atmospheres, while those of the inner group—Mars, Venus and Mercury—show but little deviation from the ordinary solar spectrum. It may be that the light received from Venus is almost entirely reflected from the upper part of the atmosphere, but in the cases of Mars and Mercury most of it has passed through the planetary atmosphere twice. As a matter of fact the atmosphere of Mercury seems to be almost negligible. It is known that the moon which is still smaller has none at all that is appreciable, and it cannot be supposed that an atmosphere exists on any of the minor planets, the largest of which (Ceres) has a mass only $\frac{1}{8,000}$ and a surface gravity only $\frac{1}{30}$ as great as the corresponding values for the earth.

The interpretation of the spectra of the outer planets, apart from the mere fact of considerable absorption, is puzzling. From the accompanying plate and Table III. it will be seen that there are one or two rather faint but broad bands in the spectrum of Jupiter which are seen to be much stronger in the spectra of Saturn, Uranus and Neptune. The two latter also contain a number of additional bands. The origin of the bands was still unknown in 1927.

Temperatures of the Planets.—A matter of special interest in regard to the planets is that of the temperature of their surfaces. Speaking generally it may be said that the surface temperature of a planet which is without appreciable heat of its own and is warmed only by the solar radiation is determined by a number of factors of which the following may be specially mentioned:—(1) The distance of the planet from the sun, the intensity of solar radiation obeying the well-known inverse-square law. (2) The degree in which the planet's surface approaches that of a perfect radiator. (3) The presence or absence of an atmosphere and the nature of such atmosphere. (4) The planet's rotation. It can be shown that a black sphere without an atmosphere rotating with sufficient rapidity to be heated equally all round would have a mean surface temperature given by the formula $T=277°/\sqrt{R}$ where T is the temperature in degrees centigrade reckoned from the absolute zero and R is the distance of the body from the sun,

taking the earth's distance from the sun as unity. But should the periods of axial rotation and orbital revolution be equal, so that the body turns always the same face to the sun, the formula becomes for the point immediately under the sun $T=392°/\sqrt{R}$. This means, *e.g.*, that on a perfectly radiating planet without an atmosphere at the distance of Mercury the point on the surface where the sun is overhead would have a temperature of 631° C (absolute). With a quick rotation the mean surface temperature would be about 445° C (absolute) or 342° F. The corresponding absolute temperatures at the distance of Mars come out 318° C

(113° F) and 224° C (−56° F), and at that of Neptune only 71° C (−332° F) and 51° C (−368° F). The actual temperatures will, of course, be affected to a large extent by the presence of an atmosphere which, while directly reflecting a large proportion of the solar rays, checks the escape by radiation of such as penetrate it and reach the planet's surface.

Until comparatively lately, however, the only available methods of estimating the surface temperatures of the planets were those based on general physical principles, and in view of the great uncertainty as to the conditions prevailing on the planets, and particularly as regards the nature of their atmospheres, the conclusions arrived at were necessarily of a highly speculative character. But in recent years great strides have been made in the development of radiometric apparatus, and by the use of thermo-couples in vacuum cells with extremely small receivers and sensitive galvanometers it has been found practicable to measure with considerable accuracy the radiations received from the planetary surfaces, and even, in some cases, from particular parts of those surfaces. In these measurements transmission screens of such materials as water, quartz, glass, fluorite, are interposed in the path of the rays which absorb the radiations in certain parts of the spectrum, and thus enable the total radiation to be resolved into a number of spectral components. For example, when a water cell is employed, the infra-red heat radiations are cut out, and the ratio of the transmitted to the total radiation of the planet provides data for determining the temperature of the planet's surface. It will be clear that if the ratio of transmission through the water cell is large the heat radiated by the planet is small, but that if the transmission ratio is small the proportion of heat rays is comparatively great. The matter is, of course, complicated somewhat by the presence of water vapour in the terrestrial and planetary atmospheres, but the necessary corrections can be estimated, and it is found that the reduction of the observations by various methods such as those based on (1) the distribution of energy in the spectrum, (2) the fourth power law and the measured water cell transmission, as worked out by Menzel and (3) a comparison with observations of the moon, all lead to satisfactorily accordant results.

The conclusions reached are of great interest. Measurements of the heat radiations from Mercury give values which support the conclusion that the planet's periods of rotation and orbital revolution are the same, and that its atmosphere is negligible or nearly so. In the case of Venus a considerable amount of heat is apparently emitted even by the unilluminated surface, which suggests a quick rotation. Observations of Mars at the Lowell observatory in 1922, 1924 and 1926, which are in fair agreement with those made at Mount Wilson, show that despite the planet's distance from the sun the temperature during the day rises well above the freezing point, and exceeds that value even at the polar regions during the summer; that the bright regions are cooler than the dark regions; that the summer hemisphere is warmer than the winter hemisphere; that afternoon temperatures are higher than those of the morning, and that low temperatures are recorded from what appear to be cloud surfaces which check the escape of heat from below. These radiometric results for Mars are consistent with telescopic observations of the surface features—particularly with the melting of the polar caps—and with terrestrial experiences of seasonal and diurnal temperature changes.

As regards Jupiter and Saturn the results obtained have given occasion for some surprise. Physical observations of the surface features of these planets, particularly the former, combined with the known low density, suggest very strong analogies with the sun, and apparently give evidence of considerable stores of heat. Yet the radiometric researches of Coblentz, Lampland and Menzel indicate a temperature of about 100° C for the visible surface of Jupiter and a value slightly higher for that of Saturn. Dr. H. Jeffreys, too, has concluded on theoretical grounds that the temperature of these planets is low. Observers, however, find it difficult to accept the position that the very large and violent disturbances and rapid changes exhibited by Jupiter can have their origin merely in solar radiation, and incline to the view that whatever the superficial temperature there must be a considerable difference between that at the centre and that of the external parts of the planet's mass. The difficulty might be removed if it can be supposed that the cloudy surfaces of Jupiter and Saturn are composed of substances which have a very low boiling point.

Habitability of the Planets.—It will be clear that the various points above referred to have an important bearing on the question of the suitability of the planets to be the abode of life. Apart from the question of temperature their low density rules out the large planets of the outer group as possible habitations for anything at all resembling human life. It is on the planets of the inner group with their solid surfaces and their proximity to the sun that the requisite conditions must be looked for. Of these planets Mercury, whose periods of axial rotation and orbital revolution are identical, with its scanty atmosphere, its extremely high temperature on the sunlit side and the intense cold of that which is in perpetual night cannot be habitable unless it be in the restricted region near the boundary of the light and dark hemispheres. Of Venus almost nothing is known apart from its resemblance to the earth in volume and mass and its possession of a seemingly cloud-laden atmosphere. About Mars much information has been gathered. Its transparent atmosphere has permitted a study in considerable detail of its surface markings and physical condition with the result that the planet is known despite its small dimensions to exhibit important resemblances to the earth. It may, accordingly, well support some form of animate life, though certain important differences in the conditions prevailing on its surface would seem to preclude its habitation by beings quite like man. More than this can hardly be said, but it may be held probable that on a planet where the required conditions are found life of some sort exists, and that at some period in such a planet's life evolutionary processes may bring its inhabitants to the status of intelligent beings.

See ASTRONOMY and articles under planetary names.

PLANETARIUM is the name given to an arrangement, made by Zeiss of Jena, for producing an artificial sky. By optical methods images of the sun, moon, planets and stars are projected on a large hemispherical dome and by mechanical and electrical means the apparatus can be revolved so as to show the principal motions. The name planetarium is apparently given because of the success with which the apparent motions of the planets amongst the stars can be shown; but the apparatus makes possible the representation of many other astronomical phenomena.

For several centuries orreries have been used to demonstrate the motion of the planets round the sun according to the Copernican system. Perhaps the best arrangement of this kind is in the German Museum at Munich where the observer can be carried in a cage which is moved in a path representing the earth's orbit. By means of a periscope he can look out on the motions of the other planets and at the stars of the zodiacal constellations shown on the wall by means of small electric bulbs. But it is impossible in a model of this nature to make the relative distances correct and thus to get the proper alignment of the various bodies. When this instrument was ordered from Zeiss in 1913 it was suggested that another astronomical model might be made depicting the heavens as actually seen from the earth and it was suggested that the heavenly bodies might be represented by electric bulbs fixed or moving on a rotating dome. This suggestion, however, was soon discarded in favour of another, due to Dr. Bauersfeld, in which the images of the bodies were projected optically on a fixed dome. The resulting apparatus has been a great success. It is found that when a dome 50ft. or more in diameter is used, the appearance is extremely like that of the actual sky. For the stars it is merely necessary to have the projector mounted so that it can be rotated about an axis parallel to the earth's axis. For the sun, moon and planets small models, true to nature, are constructed. The angles between the orbit planes are allowed for and by the use of eccentric circular motion the elliptic motion is quite closely represented. For showing say the planet Venus, the model has pins representing Venus and the earth moving round the sun. A little projector is attached to the pin representing Venus and a linkage between the planets always directs the light away from the earth. Consequently, the image of the planet on the dome

is in the correct position amongst the stars. The gearing is so arranged that the mean motions are accurately reproduced and only comparatively slight periodic errors affect the motions of the sun, moon and planets. The phases of the moon are shown by an occulting device.

The planetarium can be operated at varying speeds corresponding to the phenomenon to be demonstrated so that even such a slow motion as that of the procession of the equinoxes is within its range. To show the rising and setting of the heavenly bodies a day is compressed into an interval of from 1 to 4 minutes; to show that of the planets the diurnal motion can be put out of gear and a year run off in intervals varying from 7 seconds to 4 minutes. The original model was made for one latitude only, but in later ones, by introducing an additional axis of rotation, the latitude can be altered at will. The stars are shown brighter than they appear in the sky—the eyes of the spectators coming from the daylight would otherwise take too long to be sensitive enough to see them. It is, of course, impossible to make the sun as bright as in nature but this has the advantage of enabling the stars to be seen in the sky along with the sun and thus demonstrate the motion of the sun amongst the stars.

With the planetarium the spectator can see in an hour or so motions which can only be seen in the heavens by years of watching. When a year is compressed into a minute or two the planets can be seen chasing one another about the sky describing loops, advancing and retrograding, just as they do so slowly in nature. Great attention has been paid to details so as to make the apparatus as perfect as possible; *e.g.*, the brightness of the objects is dimmed as they approach the horizon and the light is practically cut off as the star actually reaches the horizon. A number of devices have been introduced to assist a lecturer in describing the phenomena. The date corresponding to the configuration can be projected on the dome at any time as well as the names of the constellations, and by means of a luminous pointer the lecturer can point out objects of interest. The whole demonstration is most fascinating and has attracted large audiences in a considerable number of towns in Germany where planetaria have been erected. Instruments are now being erected in other countries.

(J. N.)

PLANING-MACHINES rank in importance with the lathes and drilling-machines, and cut various kinds of plane surfaces in metal. The principle is that of attaching the metal to a long table which slides truly upon a massive bed, so that by holding a cutting tool in a slide overhead, the material becomes shaved off as the table moves. The width of surface is treated by giving the tool a cross traverse. The slide moves on a horizontal rail for this purpose, and the rail is adjustable up and down two uprights flanking the bed. Tool-slides are often put on the faces of the uprights as well, so that the sides of the work may be planed. Planing-machines are of value both for big and small articles; they may take one of the former and deal with it singly, or a whole string of small objects can be clamped in line on the table and surfaced off. (*See* also WOOD-WORKING MACHINERY; MACHINE TOOLS.)

PLANKTON is the name which is now given to the drifting (and usually microscopic) life contained in the waters of the seas, lakes, ponds and streams. Its study was begun, just prior to 1845, by the great German zoologist, Johannes Müller in the sea round Heligoland. Associated with Müller, in 1845, were his pupils, Max Müller, Busch, Wilms, Wagener and others. Ernst Haeckel, as a student of 20 years of age, was with J. Müller at Heligoland, in 1854, and began to study the plankton. "Then," said Müller, "you have once entered this pelagic, magic world you will not easily leave it again." Rapid extension of plankton investigation followed, both in Germany and in Great Britain, and the great names associated with this branch of 19th century marine biology are Heinrich Müller, A. Kölliker, C. Gegenbaur, Leuckart, Carl Vogt, T. H. Huxley and McIntosh.

In 1873–76 the "Challenger" made her voyage of circumnavigation and great collections of plankton were made in all the seas of the world. Many other voyages have since been made but there has been none that did so much work as was carried out during those three years under the direction of Wyville Thomson and John Murray. Another equally great landmark was the "Plankton Expedition" carried out by the "National." Victor Hensen, of the University of Kiel, led this expedition (which worked in the Atlantic ocean) and with him were associated Brandt, Schütt, Fischer and Krümmell. All subsequent work on the plankton has been dominated by the methods elaborated by these workers and by the extraordinarily fertile ideas of Hensen, and these methods, with their results, make up the modern science of hydrobiology.

The Plankton in General.—The passively drifting, pelagic life of the sea and of fresh waters consists mainly of microscopic organisms. There are some large plants and animals that are planktonic in their habits: such are the gulf-weed (*Sargassum*), medusae, siphonophores and other jelly-fishes; some molluscs like the pteropods ("whale-feed"), the pearly nautilus, etc. It is not usual, however, to consider these relatively large plants and animals when we are discussing the plankton: in practice we take the latter to mean the organisms which are, as a rule, invisible to the naked eye, because of their minute size and translucency. Even the most transparent sea water may contain very large numbers of these microscopic organisms and sometimes they are so abundant that the water may be coloured, or turbid, and they may even tint snow and ice. A practical distinction is made between the Macroplankton, which can be caught by filtering the water through very finely woven silk cloth, and the Microplankton, which are so small that they escape through the pores of the finest fabrics that can be employed. Later on we shall consider more fully the methods of collecting the plankton. A further practical distinction, in discussing distribution, is that between the Transitory Plankton and the Permanent Plankton. The former category includes all those organisms which have a brief, pelagic, drifting stage in their life history, after which they develop into actively swimming, large animals (the Nekton), or into rooted or sedentary plants and animals (the Benthos). The latter category includes a multitude of species of organisms which live throughout their lives as planktonic, passively drifting individuals. It is customary to distinguish between Oceanic and Neritic Plankton, the former inhabiting water which is far from land and the latter being practically restricted to the zone of shallow water near the Continental coasts. Then there are many plankton organisms that prefer to live near the surface of the sea and these we call the Epiplankton, while there are others that habitually live in the deeper layers of the ocean: these make up the Bathyplankton. Finally the different oceans, seas, zones of latitudes, etc., tend to harbour characteristic plankton communities, so that a naturalist who is very familiar with plankton investigations can often say where an unknown sample has been collected.

After this general survey we may now consider the various kinds of organisms that occur in the plankton.

The Transitory Plankton.—A great number of marine organisms "spawn" in the general sense—that is, they discharge their spores, eggs and larvae into the sea, where these things simply drift about while they undergo development. After the latter process is complete the organisms leave the plankton communities, either to settle down on the sea-bottom or to roam about in the sea as freely-locomotory animals. Thus the eggs and larvae of innumerable marine species are transitorily planktonic organisms, finally becoming benthic or nektic ones. Benthos includes all the organisms that live on or are attached to the sea bottom, while nekton includes those others that are actively locomotory in their habits. (*See* MARINE BIOLOGY.)

Thus most of the fishes spawn, emitting their eggs and spermatozoa into the sea water, where the processes of fertilization and embryonic development occur. When embryonic development ends the little fish is a larva, and as such it simply drifts about in the sea. Finally its development is completed by a metamorphosis and then it assumes the form and habits which are characteristic of its species. It leaves the plankton and becomes a nektic animal. Most of the marine Crustacea reproduce in the same way, that is they may directly emit eggs into the sea,

or the parents may, for a time, carry these eggs attached to their bodies, but in most cases the embryos develop into larvae which are always small, practically non-migratory and which finish their development while drifting in the plankton. Many of the Mollusca lay their eggs (enclosed in cases, or cocoons) on the sea bottom, but others emit the eggs and sperms into the water. In all cases, however, the larvae drift about for a time. Just the same general life-history is displayed by most of the worms, the polyzoa and practically all the echinoderms, sponges and coelenterates. The rooted algae liberate their zoospores into the sea on the littoral and shallow-water zones and there these myriads of (even microscopically) tiny organisms drift about and perish.

The wealth of life that is so produced is incredibly great. Even one large cod will spawn annually several millions of eggs, all of which exist for a short time in the plankton, and some of which become larvae and small baby cod. So also with almost every kind of marine animal: its eggs that are spawned every year must generally be counted by the thousands or hundreds of thousands. Yet, on the average, of all the eggs produced by any marine animal only one or two can undergo development and growth up to full reproductive maturity. The remainder, destined to perish in the struggle for existence, have their life-phase for a few weeks or months in the hordes of transitorily planktonic organisms.

The Permanent Plankton.—In all parts of the seas and oceans the plankton always contains great numbers of organisms that have this habitat throughout their whole lives. There are many large, permanently planktonic organisms—some algae; many medusae (which are sometimes so numerous as to make a visible, coloured carpet on the surface of the sea); many other coelenterates (such as the Siphonophores and the Ctenophores); some worms; some molluscs like the pearly nautilus, and the Heteropods and Pteropods (the latter may exist in great shoals and form the food of the whalebone whales). These large plankton animals and plants are, however, few and unimportant when compared with the multitudes of the microscopically small animals and plants which abound even in water that appears, to the naked eye, to be perfectly clear and barren.

Among the Crustacea the little animals called Copepods, Schizopods, Ostracods, Cumacea, with some less abundant groups are always and everywhere present in the plankton and sometimes they are extraordinarily abundant. They live mainly in the upper layers of the sea, but many species are also found in very deep water. Their significance, even for human affairs, is very great for they are the food of such fishes as herrings, pilchards, sprats, like and other kinds that are regularly caught by the fishermen. Many other marine animals, of course, eat them. They may be so very abundant that sufficiently large numbers to cook and eat may be taken by fine nets drawn through the sea.

Worms belonging to the groups called Polychaetes and Chaetognaths (these are the bristly jointed worms and the translucent "arrow-worms") abound. The only planktonic vertebrate (or rather "chordate") animals are some of the Tunicates, and one kind of these creatures—the salps—may at times be so very abundant in the sea as to clog and sink the drift nets set by the herring fishermen. The Heteropods and Pteropods are the only permanent plankton dwellers belonging to the Mollusca. There are no echinoderms that are always planktonic but the beautiful larvae of these animals live for a time pelagically. The Coelenterates are, some of them, permanently planktonic (*see* above), but most of them (the zoophytes, sea anemones, corals, etc.) live on the sea bottom and their larvae appear for a short time only among the plankton. None of the sponges are permanent plankton denizens.

Great numbers of species of unicellular animals and plants are always planktonic: we shall notice the principal kinds very briefly, premising that their full description means writing great books on zoology and botany. Among the Protozoa are the Foraminifera and Radiolaria—the former characterized by their calcareous and the latter by their siliceous skeletons. These animals are microscopic in size (though sometimes big enough just to be discerned by the naked eye). They are found everywhere in the sea and they are so numerous that extensive regions of ocean-floor, at depths of about 2 to 3m., are covered with fine oozes made up almost entirely of the shells of Foraminifera and Radiolaria that

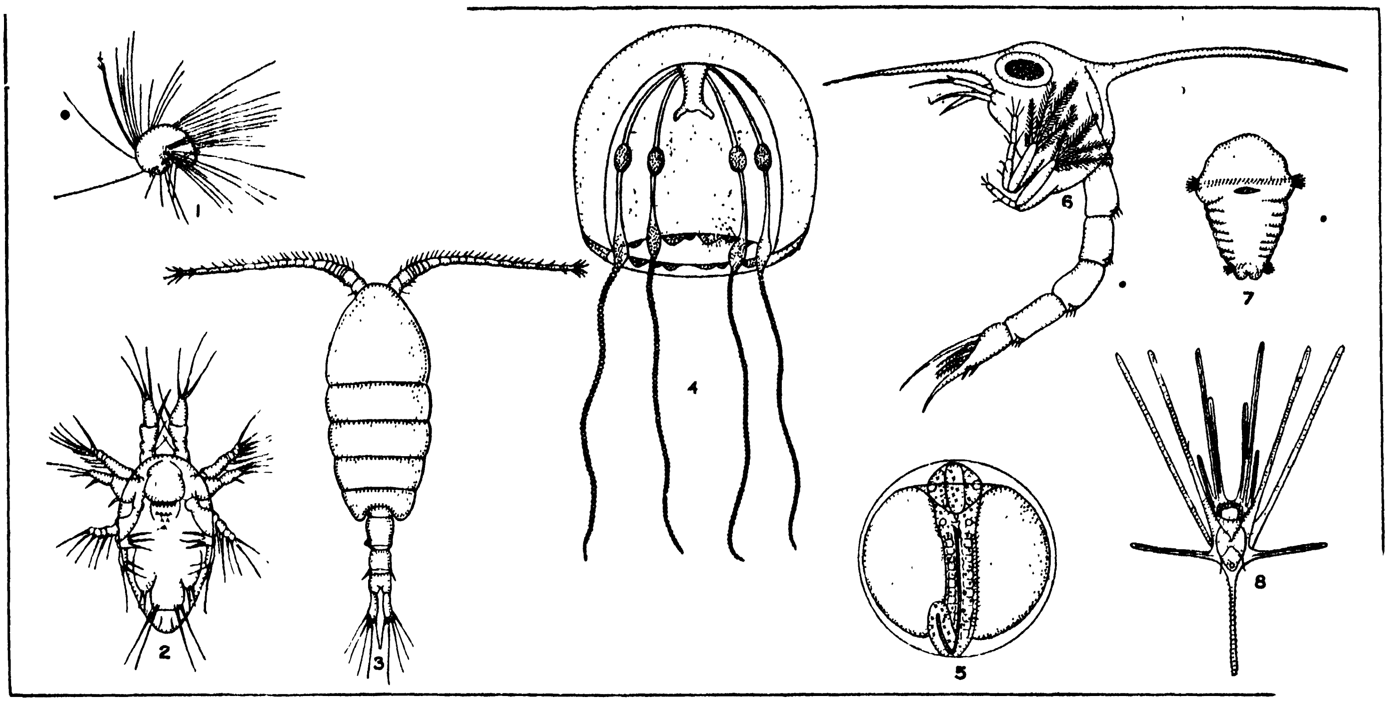

FIG. 2.—VARIOUS LARVAE OF MARINE ANIMALS (HIGHLY MAGNIFIED)

live and die in the upper layers of the ocean. These shells are beautiful and interesting objects when seen under the microscope. Very important from the human point of view are the Peridinians: these are unicellular organisms that can be regarded either as plants or animals and they are about as abundant as the Protozoa that we have already mentioned. They also have very elegant shells made of a kind of cellulose material which is impregnated with silica. Great numbers of Peridinians live in the sand and mud in the very shallow sea bottom near the land, but most of the species are pelagic—that is, they are permanently planktonic. The pelagic Peridinians are important food materials for some fishes—mainly the pilchard (when it is in the sardine stage). These organisms are interesting from another aspect—it is they that mainly cause the phosphorescence of the sea. Sometimes, when the sea is very fiery, an organism called *Noctiluca* is so abundant that the water may be visibly turbid and discoloured.

The Diatoms are to be regarded as unicellular, algal plants, and they are, on the whole, the most abundant of all the planktonic organisms. They have external, transparent, siliceous shells which are elegant in form and are often sculptured with beautiful patterns. They exist everywhere in water—in ponds, lakes, on the mud and sand of the foreshore and sea bottom, attached to weeds, etc.—the main restriction on their presence is the absence of light, for, being green plants, they cannot live except in the presence of solar radiation. There are innumerable species and they are so abundant in the ocean that millions of square miles of bottom, at about 2,000 fathoms in depth (and mainly in the Antarctic) are covered by the dead shells of Diatoms.

The Microplankton.—The above observations apply to the larger planktonic organisms, but there are numerous species which are not captured by using the ordinary "tow nets" (presently we refer to the methods that are employed by the planktologists). These smaller species (the Micro- or Nannoplankton) include many minute Diatoms, Peridinians, shelled and naked Protozoa, Flagellates, unicellular Algae and algal zoospores. There are, of course, hosts of marine bacteria, but these we do not consider in this connection. We shall see that, in point of numbers of individuals, the microplanktonic organisms far exceed the larger forms.

The Seasonal Variations in the Plankton.—Everywhere in the sea and in fresh waters the composition and abundance of the plankton change with the season. To some extent the nature and sequences of these changes depend on the re being investigated and this is particularly the case sider the larvae, for the nature and abundance of pend on the nature of the local benthic and nek however, we consider the North Atlantic regio general descriptions will apply, to some extent, most local regions.

The cold and dark months, December to Febr periods when the marine plankton is scarce and and Peridinians, in particular, are relatively fe is because of the feeble intensity of sunlight, for the growth and reproduction of these orga time about March or April there is a great outb sea. Certain indispensable food materials (in compounds, silica and phosphates) have been ac ing the dark months; in the spring there is a ri perature and this acts as a stimulus to vital proce main factor is the increase in the length of the day an ing intensity of sunlight. The result of these changes the vegetable plankton, but particularly the Diatoms, stimulated to reproduce, so that there is almost an explosiv burst of life in the sea and great swarms of Diatoms invade shallow sea areas. This is the great event of the year—the "ver nal maximum" of vegetable life in the sea.

Immediately following it comes the reproduction of the nektic and benthic animals. Hosts of Fishes, Crustacea, Mollusca, Echinoderms and worms spawn their eggs into the water, or deposit them on the sea bottom. The eggs hatch out and the waters of the sea teem with larvae. The latter must feed and they utilize the vegetable plankton (Diatoms, algal spores, etc.). The production of animal larvae lasts into the early summer (or even later with some species), but while it goes on there is a diminution in the abundance of the Diatoms. Those indispensable food-stuffs which accumulated during the winter months are largely used up while the vernal maximum of vegetable plankton lasts. The extraordinary abundance of Diatoms therefore falls off during the months of June to August, but about then the Peridinians begin to increase. The summer months are characterized then by a relative scarcity of Diatoms, a great increase in the Peridinians, an abundance of larvae belonging to many groups of invertebrates and a great abundance in the Copepods.

In the autumn or early winter the Diatoms sometimes increase

again—there is an autumnal maximum. But this is a very brief phase and with the shortening of the day and the drop in sea temperature towards the annual minimum all kinds of planktonic life in the sea decrease. In this very summary account of the seasonal change stress has been laid on certain physical agencies —light, temperature and inorganic food substances—that are regarded as of importance, but we must never forget that intrinsic causes are also operative. Heredity has implanted, in the organizations of all marine organisms, a cyclical tendency so that the annual outbursts of reproductive activity are stimulated, or set off, so to speak, by the seasonal changes.

The Abundance of the Plankton.—There is no part of the seas and oceans where planktonic organisms do not occur. Even in the greatest depths of the ocean we suspect that certain micro-crustacea exist. Under the ice, in polar regions, rich collections may be taken and there are abundant algal organisms in the pools that form in hollows on the surfaces of ice-floes in the summer. Snow and ice may actually be tinted with Diatoms and other organisms. The richest plankton in any part of the world-ocean is that found just on the borders of the polar seas, in the regions of melting ice. In general the temperate and cold seas are rich plankton, while the tropical and warm waters are relatively

a sea area can be obtained by indirect methods.
rst, that all animal life in the sea depends on
ıe animals can only subsist by eating other ani-
but the plants can use as their source of food-
ıc acid that is dissolved in the water. Utilizing the
.light they can synthesize this carbonic acid into
ȷ other vegetable substance. Now it is mainly the
'eridinians (and other plankton organisms that have
ıble mode of nutrition) that do this, for the total mass
ıe rooted algae must be very small in comparison with
.ass of the vegetable plankton. It is possible, by routine
.emical methods, to find out how much carbonic acid is removed
rom solution in a sea area, during the spring and summer seasons, and then converted into carbohydrate by the activity of the vegetable plankton. The result is very surprising: at least 300,000 kilog. of dry organic carbohydrate must be produced during a single season per square kilometre of sea surface. Or, expressed in more familiar terms, a spring and summer of organic production in the sea gives origin to about ten tons of moist vegetable substance per acre of sea. This is the marine harvest due to the activity of the vegetable plankton: at present man reaps only a very small fraction of it in the shape of the fishes and other edible animals that he catches.

Methods of Studying Plankton.—A veritable wonderland awaits the amateur naturalist who can spend a short time at the seaside during the spring months. He will require a student's microscope (magnifying 50 to 500 diameters) and some cheap, home-made apparatus. The net is simply a conical bag of the finest and strongest muslin obtainable: it is about 1 to 2ft. in diameter and about 4ft. long. Its mouth consists of an iron ring, to which a selvage of strong canvas is laced. The net is sewn on to this canvas edging. It is towed in the sea behind a rowing boat for about half an hour.

When the net is hauled it is drained of water and turned outside in. The pointed end is then rinsed in sea water contained in a 2 lb. glass jam jar. A small sieve is made by loosely tacking a piece of muslin on a square wooden frame about 4in. along each side. The water containing the catch is then slowly poured through the central part of the sieve. Then the latter is turned upside down and the plankton is washed off into a little sea water in the bottom of a saucer. This will now be a thick, greenish turbid mass. A dipping tube is made (like a fountain pen filler, but with a wider opening) and some of the plankton is lifted with this and put into a watch glass, which is then examined under the microscope. Examined day by day the spring and summer plankton is full of the most beautiful things.

Nets contrived to fish quantitatively are also used. In such investigations fine miller's silk bolting cloth is used. This has meshes of over 100 to the inch. Heaps of organisms escape through this net. To catch the very minute plankton the water must be centrifuged, or cultures are made in an analogous way to those employed by bacteriologists. Elaborate methods have been evolved for counting the organisms taken in a plankton catch.

Bibliography.—There is a huge literature on plankton but many general papers are cited, and their source stated, in *The Marine Plankton*, by Johnstone, Scott and Chadwick (Liverpool, 1924).

(J. A. J.)

PLANTAGENET, a surname conveniently, but unhistorically, applied to the royal line descended from the union of Geoffrey, count of Anjou, with the empress Maud, who are now styled by historians the Angevin house. It was, historically, only a personal nickname of Geoffrey, as was "Curtmantel" of his son (Henry II.), and was derived from his wearing in his cap a sprig of the broom (*genet*) plant. When the fashion of personal nicknames passed away, the members of the royal house were usually named from their birthplace, as Thomas "of Brotherton," Thomas "of Woodstock," and so forth. But Edward I. and his younger brother, the founder of the house of Lancaster, had still nicknames respectively, as "Longshanks" and "Crouchback." In the later days of the dynasty the surname of Beaufort was adopted by the legitimated issue of John of Gaunt by Katherine Swynford, but that of Plantagenet was bestowed on Arthur, natural son of Edward IV., who was created Viscount L'Isle. It appears, however, to have been adopted as a surname by Richard duke of York (father of Edward IV.) some 12 years before his death.

At the death of Geoffrey's grandson, Richard I., his younger brother John succeeded. John's younger son Richard, king of the Romans, left a son Edmund, earl of Cornwall, with whom his line ended; his elder son Henry III. left two sons of whom the younger was created earl of Lancaster and was grandfather of Henry, earl of Lancaster, whose heiress married John of Gaunt (*i.e.*, Ghent). (*See* Lancaster, House of.) John of Gaunt's next brother, Edmund of Langley, founded the Yorkist line. (*See* York, House of.)

Although no other dynasty has reigned so long over England since the Norman Conquest, the whole legitimate male issue of Count Geoffrey Plantagenet is clearly proved to have become extinct in 1499.

PLANTAGINACEAE, a family of dicotyledonous herbs, the best known members of which are the plantains (*Plantago*), cosmopolitan weeds, of which five species occur in Great Britain and upwards of 30 in the United States. (*See* Plantain.) The family contains three genera and about 200 species. The seeds of *Plantago Psyllium* (Mediterranean) are used in silk and cotton manufacture. The flowers, usually hermaphrodite and inconspicuous, are wind-pollinated.

PLANTAIN, a name given to certain plants with broad leaves. This is the case with certain species of *Plantago, Alisma* and *Musa,* to all of which the term is popularly applied. The species of *Plantago* (family Plantaginaceae) are mostly weeds with a dense tuft of radical leaves and scapes bearing terminal spikes of small flowers; the long spikes of *P. major,* when in seed, are used for feeding cage-birds; *P. lanceolata,* so called from its nar-

row lanceolate 3-6 ribbed leaves, is popularly known as ribwort; *Alisma Plantago-aquaticum* (family Alismaceae) is the water-plantain, so called from the resemblance of its broad ribbed aerial leaves to those of *P. major*. The tropical fruit known as plantain belongs to the genus *Musa*. (*See* BANANA.)

PLANTAIN-EATER: *see* TOURACOU.

PLANTATION, literally the placing of plants in the ground, hence a place planted or a collection of growing things, particularly used of ground planted with young trees. The term was early applied, in a figurative sense, to the settlement of people, and particularly to the colonization of North America in the early part of the 17th century and to the settlement of Scottish and English in the forfeited lands in Ireland. The practice of sending convicted criminals to serve on the plantations in the colonies became common in the 17th century (*see* DEPORTATION). For "plantation songs" *see* NEGRO.

PLANT BREEDING. The first object of plant breeding is to produce new varieties superior to one or more of the old ones. Superiority means agricultural superiority and is measured by net monetary return per acre. It may be sought in many directions, of which yielding capacity and quality of produce are chief. In many countries and for a diversity of crops, resistance to disease has a great importance. Rapid growth is sometimes a transcendent consideration because it ensures escape from an intensely hot summer or from early frosts.

The earliest efforts in crop improvement consisted of the simple practice, many centuries old, of picking out the finest plants as the source of seed for the next season. During the 19th century the two methods of breeding now universally used—selection of single plants and artificial hybridization—were brought to a relatively high pitch. But they were entirely empirical and, uninformed by scientific knowledge, appeared incapable of any substantial modification. Then, swiftly, with the opening of the 20th century, came Mendel's laws of heredity, Johannsen's theory of pure lines, and the mutation theory of de Vries. These great advances, while recasting biological science, gave to plant breeding an orderly basis and a new outlook.

An ordinary field crop, especially in a backward or agriculturally young country often contains plants of several different varieties. By selecting and separately propagating single plants it is possible to produce seed stock of these several varieties. Those which, on test, prove best, may be introduced into general cultivation. This procedure, the selection method of breeding, is widely used. Chevallier and Goldthorpe barleys and also Potato and Sandy oats, all of great value in their day, arose from selected single plants. Dr. E. S. Beaven's Archer and Plumage barleys are other notable selections. The earlier exponents sought to carry improvement further by restarting from the best seed from the best plant among the progeny of a single plant. Johannsen demonstrated the futility of this, showing that, in self-fertilizing plants, the descendants of a single plant were normally a "pure line," *i.e.*, all alike save for purely fortuitous differences and such as to breed true on producing seed.

Normal constancy in reproduction may, in some instances, be varied by the production of a "sport" or new type. The biological processes responsible for this happening—or mutation—are still imperfectly understood. But de Vries demonstrated that a mutation, once produced, remains constant in subsequent generations. Thus a valuable mutant type is a permanent asset to agriculture and de Vries' discoveries gave fresh stimulus to the selection method of breeding. Mutations may arise either in the reproduction of plants by seed or as buds. In citrus fruits mutant buds arise with marked frequency and it is by finding and propagating them that Californian growers of the navel orange have developed a considerable number of new types, some of all-round superiority to the original navel orange which was introduced from Brazil.

Artificial hybridization or crossing, now the chief method of breeding, may be illustrated by a simple hypothetical example. Suppose it were desired to breed a wheat having short straw and earliness in ripening (short-early); that the only short straw variety adapted to the country concerned was late ripening (short-late); and that the only available early ripening variety had tall straw (tall-early). The actual half-bred or first-hybrid (F_1) obtained by hybridizing the two chosen varieties would be about intermediate in straw and maturity. If allowed to self-fertilize it would form seeds from which would grow the second hybrid generation (F_2) plants. Mendel's laws make it possible to predict (i.) That among the F_2 plants would be four types, viz., short-late: short-early: tall-late: tall-early. (ii.) That the four types would occur in certain definite proportions (in other crosses, involving different plant characters, the proportions might be different from these but they would always be constant and systematically explicable for any one case) (iii.) That only a proportion of the F_2 plants of any one type would breed true to type.

By raising separate progenies from the seed of all short-early F_2 plants it would be possible to select those lines which were fixed or true breeding.

Unfortunately yield and almost all attributes of agricultural consequence do not behave with this hypothetical simplicity. They are, indeed, not single units of inheritance but combinations of many. Thus the breeder cannot pick the ideal F_2 plant and by simple seed propagation build up a stock of an ideal new variety. In cereals, for instance, 10 to 12 years of continual selection must follow on the act of hybridizing before it is possible to obtain a uniform true breeding type having the desired combination of characters from the two parent forms. Not even the keenest eye, the ripest experience or the utmost resource of science is able to detect, in the early stages of breeding, which is best of the new types that hybridization has brought into being. It is necessary by successive years of study to eliminate types one by one until a few remain. These must then be systematically tested for yield and the other characters of importance. The test methods associated with plant breeding represent a specialized field of applied science.

The older hybridists frequently sought to cross widely different parents, as for instance cabbage by turnip or two markedly divergent wheats. Complication or failure was the usual result. Morgan's chromosome theory of heredity has now furnished the breeder with both a test and an understanding of the limits of cross-compatibility.

WHEAT AND OTHER CROPS

Improved varieties of wheat take first rank, and among them the Marquis wheat of Canada is pre-eminent in point of acreage. In 1892, Dr. William Saunders crossed Hard Red Calcutta, a commercial grade rather than a variety, and Red Fife, then the standard wheat of western Canada. Subsequently his son, Dr. Charles E. Saunders, selected one type from the progeny. This became commercially established in Canada in 1911 under the name of Marquis. In 1917 it constituted 80% of the wheat of the prairie provinces. Imported into the United States in 1913 it had, by 1919, a spread of 11,900,000 acres. Only one wheat is now more widespread in America; this is Turkey, which, with twice the area of Marquis, is a striking example of introduction, for it was brought from Russia by Mennonite immigrants. Earlier maturity, the primary distinction between Marquis and the Red Fife and other wheats it has displaced, makes for immunity from rust, drought and frost.

India, with great environmental diversity and characteristic impurity of native varieties, has proved a fine field for the breeder. Under Dr. A. Howard, the Pusa Institute has established selected wheats which are ousting the older forms. Pusa 12 and Pusa 4 have an area of 500,000 acres in the United Provinces, while Punjab 11 is grown in the canalized parts of the Punjab on nearly twice this scale. Helped by the provision of good seed, these new products are estimated to represent an annual gain to the cultivators of £1,000,000.

Something of romance attaches to the introduction into Argentina of a wheat from the Szechwan province of China. It has proved highly resistant to *Puccinia triticina*, the rust which more than anything else threatened to suppress the great promise of wheat-growing in South America. The introducer, Mr. W. O Backhouse, has now raised hybrids which, both rust resistant and generally superior, are fast becoming the standard forms.

From the Swedish station, Svalöf, have come a number of new wheats, barleys, oats and peas; Swedish Iron wheat has added to its laurels by gaining a hold in Great Britain; millers, however, dislike the thick skin and the quality of its grain. The Little Joss and Yeoman wheats bred by Prof. Sir R. H. Biffen and introduced in 1912 and 1917, occupy one-tenth and one-fifth respectively of the whole wheat area of the 14 principal producing counties. Little Joss, a hybrid from Ghirka (Russian), and Square Head's Master (British) are the only forms with a definite resistance to yellow rust (*Puccinia glumarum*), besides possessing a marked standing capacity and a curiously wide soil adaptation. Yeoman is also a product of premeditated synthetic breeding. The parents were Browick (British) and Red Fife—the best bread-making wheat. Heavy yield and great standing power are merits it shares with the best of the older forms; but its quality or bread-making capacity has set a standard formerly believed impossible in British wheats.

Barley.—Barley is of peculiar interest because the quality of beer-making kinds is nearly as important as the yield. At the end of the 19th century Chevallier and Standwell were the prevailing forms in Ireland. Archer barley was introduced from England in 1900, and Irish Archer, a selection made by Dr. H. Hunter, soon displaced the older varieties. An even more marked success attended his hybrid Spratt-Archer (derived from a cross between Archer and Spratt, the latter being an old form with special adaptation to peaty soils), distinguished by high yield, exceptional standing power and superior quality; it now occupies almost 90% of the barley area of Ireland. It is estimated that £40,000 spent on breeding and testing in Ireland during the period 1905–25 has brought an increase equivalent to £250,000 per annum. Contemporaneously the selections, Archer and Plumage, introduced by Dr. E. S. Beaven of Warminster, have contributed to the prosperity of English growers.

Roots.—Roots, such as potatoes which flower uncertainly and mangolds whose varieties freely intercross in the field, are difficult subjects. But mangolds and swedes have yielded to that systematic patience which has done so much in Danish agriculture. Helweg, in Denmark, first made clear that the only sound basis of estimation for mangolds was yield of solid matter per acre and not mere wet bulk. Next he demonstrated that different forms or strains within any one variety might be widely divergent in gross yield and percentage of solid matter. Indeed, two strains of the same variety might correspond to a difference of £6 to £8 in value of feeding material from one acre. The best strains were picked out, and by persistent teaching all bad strains were forced out of cultivation; good seed was ensured, and roots came to have a greater feeding value per acre than corn. In Denmark the area under roots has steadily grown, and when the World War stopped the importation of feeding-stuffs it was roots that saved Denmark. There was a time when wart disease (*Synchytrium endobioticum*) appeared to threaten wholesale destruction of British potato crops. But steady production of immune varieties, reinforced by appropriate legislation, may now be said to have brought security to the one great crop in which this country is still self-supporting.

Other Staple Crops.—Rice in Malaya and South India, the millets in India, the Fulghum oat of Texas and Kansas, the hybrid round-tipped tobacco of Connecticut, Svalöf's Victory oat, which has proved itself to be one of the best oats grown in Great Britain, and Dr. C. A. Barber's new sugar-canes in India are among many other valuable new products of the last decade.

PLANTIN, CHRISTOPHE (1514–1589), French printer, was born in a village near Tours (probably Saint-Avertin). He learned bookbinding and bookselling at Caen, and, having married in that town, settled in 1549 as bookbinder in Antwerp, where he was soon known as the first in his profession. A bad wound in the arm seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was *La Institutione di una fanciulla nata nobilmente*, by J. M. Bruto, with a French translation, and this was soon followed by many other works in French and Latin, which in point of execution rivalled the best printing of his time, while the masters in the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562, Plantin himself being absent in Paris, his workmen printed an heretical pamphlet, which caused his movables to be seized and sold. It seems, however, that he recovered a great deal of the money, and in 1563 he associated himself with some friends to carry on his business on a larger scale. Among them were two grandnephews of Dan. Bomberg, who furnished him with the fine Hebrew types of that renowned Venetian printer. His editions of the Bible in Hebrew, Latin and Dutch, his *Corpus juris*, Latin and Greek classics, and many other works produced at this period are renowned for their beautiful execution and accuracy.

A much greater enterprise was planned by him in those years—the publication of a *Biblia polyglotta*, which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II. king of Spain, who sent him the learned Benedictus Arias Montanus to superintend the work. It was finished in five years (1569–73, 8 vols. folio). Plantin earned little profit, but received the privilege of printing all liturgical books for the states of King Philip, and the office of "prototypographus regius." Though outwardly a faithful son of the church, he was till his death the partisan of a mystical sect of heretics; and it is now proved that many of their books published without the name of a printer came from his presses together with the missals, breviaries, etc., for the Roman Catholic Church.

Besides the polyglot Bible, Plantin published in those years editions of St. Augustine and St. Jerome, the botanical works of Dodonaeus, Clusius and Lobelius, the description of the Netherlands by Guicciardini, etc. In 1575 his printing-office reckoned more than 20 presses and 73 workmen, besides a similar number that worked for the office at home. But in Nov. 1576 the town was plundered and in part burnt by the Spaniards, and Plantin had to pay an exorbitant ransom. He established a branch of his office in Paris; and when in 1583 the states of Holland sought a typographer for the newly erected university at Leyden, he left his much reduced business in Antwerp to his sons-in-law John Moerentorf (Moretus) and Francis van Ravelinghen (Raphelengius), and settled there. When in 1585 Antwerp was taken by the prince of Parma and affairs became there more settled, he left the office in Leyden to Raphelengius and returned to Antwerp, where he worked till his death on July 1, 1589. His son-in-law, John Moretus, and his descendants continued to print many works of note "in officina Plantiniana," but from the second half of the 17th century the house began to decline. It continued, however, in the possession of the Moretus family, which religiously left everything in the office untouched, and when in 1876 the town of Antwerp acquired the old buildings with all their contents, for 1,200,000 francs, the authorities created one of the most remarkable museums of its kind in existence, the Musée Plantin, opened Aug. 19, 1877.
